 Elmassian. Colour photography. 10,155 and 10,180. Apr. 12.
 Gorsky. Three-colour photography. 10,955. Apr. 20.
 Mills. Photographic transfer processes. 10,823. Apr. 19.

COMPLETE SPECIFICATION ACCEPTED.

28,287 (1919). Christensen. Hardening photographic films during development. (135,477.) Apr. 28.

I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Furnaces [; *Cylindrical gas-fired* —]. A. B. Chantaine, Marcinelle, Belgium. Eng. Pat. 18,473, 8.8.14. Int. Conv., 10.9.13.

THE gas and air are admitted under slight pressure through separate ports or burners tangentially to the inner wall of a cylindrical chamber, a gas inlet being arranged immediately behind each air inlet, so that the air is thrown outwards against the inner wall of the furnace; the pressures of the air and of the gas are independently adjustable. Separate outlets for products of combustion may be provided for each pair of gas and air inlets.—B. M. V.

Distillation; Continuous fractional —. A. M. O'Brien, Abadan, Persian Gulf. Eng. Pat. 140,140, 13.12.18. (Appl. 20,765/18.)

IN a series of stills for the continuous distillation of petroleum or other substance the stills decrease in size approximately in proportion to the amount of liquor to be distilled in them; the condenser tanks are also made in corresponding dimensions, and the same cooling water may be used in all of them, starting at the largest or coolest. Some (or all) of the products of combustion may be transferred from furnace to furnace, any additional heat necessary being made up by auxiliary burners or furnaces.—B. M. V.

Refrigerating processes; Solution for absorption —. C. Delaygue, Marseilles. Eng. Pat. 140,356, 23.12.13. (Appl. 367/20.)

IN the ammonia absorption refrigeration process the following is used as the absorbing liquor:—Ammonium nitrate 3 grms., trimethylamine 2 grms., liquefied ammonia gas 554 c.c., and water to 1 litre. The absorptive power of ammonium nitrate solution for ammonia is greatly increased by addition of trimethylamine.—B. M. V.

Gases; Electrical treatment of —. L. Bradley, East Orange, N.J., Assignor to Research Corporation, New York. U.S. Pat. 1,333,790, 16.3.20. Appl., 28.6.15.

THE apparatus comprises a number of rigid discharge electrodes, arranged vertically and axially within a number of opposing tubular electrodes, with radially adjustable flanges fixed longitudinally on the discharge electrodes. The discharge electrodes are connected at their upper and lower ends respectively to insulated frames above and below the tubular electrodes.—B. N.

Gases; Apparatus for electrical treatment of —. J. C. Davidson, Vancouver, B.C., Assignor to International Precipitation Co., Los Angeles, Cal. U.S. Pat. 1,334,231, 16.3.20. Appl., 3.2.17.

THE apparatus comprises a gas receiving chamber, a discharge electrode mounted on an insulator, and a gas inlet provided with a deflector surrounding the insulator, and situated in the path of the gas to protect the insulator from the deposition of material suspended in the gas. Means are provided for supplying liquid to the insulator to remove deposited material. The insulator comprises a bushing of fragile material extending through the wall of the gas chamber, and connected to it by a yielding medium; a conductor extends through the bushing and is connected to the discharge electrode, and there is a support for the conductor outside the chamber.—B. N.

Electrical purification of gases; Insulator for use in the —. Siemens-Schuckertwerke, G.m.b.H., Siemensstadt. Ger. Pat. 316,498, 13.10.18.

THE leads to the high-tension electrodes are em-

bedded in a number of insulating plates arranged within the precipitation chamber so that their planes are at right angles to the direction of flow of the gas. The plates occupy the upper part of the chamber, and their transverse length equals that of the chamber, so that no appreciable flow of gas occurs within the space between two adjacent plates. The high-tension electrodes are connected to the embedded leads and alternate with low-tension gauze electrodes.—J. S. G. T.

Electrical purification of gases; Appliance for the —. Siemens-Schuckertwerke, G.m.b.H., Siemensstadt. Ger. Pat. 318,132, 29.5.18.

THE material precipitated from the gas collects in a chamber, beneath the stream of gas, in which a number of easily removable slides or flaps are arranged at right angles to the direction of flow of the gas, in order to prevent motion of the gas in the collecting chamber.—J. S. G. T.

Electrical purification of dusty gases; Process for —. H. Püning, Münster. Ger. Pat. 318,772, 11.2.19.

AT intervals such a velocity is imparted to the gas stream as will enable it to detach and carry forward from the electrodes any deposited dust.—J. S. G. T.

Grinding machine. W. Travell, New York. U.S. Pat. 1,333,946, 16.3.20. Appl., 9.3.16.

A GRINDING mill comprises a shell provided with partitions having central openings and forming internal circumferential grooves containing grinding rollers. Adjacent partitions communicate through openings, out of alinement with respect to each other, and permitting passage of material.—B. N.

Filter; Continuous electrical mechanical —. A. F. Meston, Assignor to Research Corporation, New York. U.S. Pat. 1,334,160, 16.3.20. Appl., 23.2.18.

AN apparatus for filtering a liquid is provided with two electrodes, one of which is formed of a drum with a porous rim and mounted so as to be rotated, the speed of rotation varying in proportion to the current flowing through the circuit. The porous rim is surrounded by a filtering medium, and the liquid is passed between the electrodes.—B. N.

Catalysers; Composition for making —. C. Ellis, Montclair, N.J. U.S. Pat. 1,335,161, 30.3.20. Appl., 21.8.19.

A COMPOSITION which yields a catalyst when heated consists of a basic compound of nickel ground with a small amount of oil.—A. B. S.

Contact-substances; Ceramic support for —. V. Zieren, Berlin-Friedenau. Ger. Pat. 317,979, 25.10.17.

Porous ceramic material, preferably in the form of small tubes with projecting rims, is employed as a support for contact substances. The diameter of the tubes should not exceed 20 mm., and the thickness of the walls 2 mm. The material is impregnated with, for example, a platinum solution, and this reduced, so that the tube becomes coated internally and externally with metallic platinum.—J. S. G. T.

Recovering dissolved or finely divided material; Process for —. I. Ebers, Ahrensburg. Ger. Pat. 309,102, 9.1.18. Addition to 306,484 (this J., 1920, 258 A).

THE process of atomising the liquid flowing from the pressure vessel is assisted by introducing some of the vapour of the liquid at the jet through which the liquid is sprayed.—J. S. G. T.

Concentrating liquids; Process and apparatus for —. A. Herrlich, Halle. Ger. Pat. 315,035, 21.3.18.

THE liquid to be concentrated flows downwards over a number of hollow plates heated internally, so that the briskly boiling liquid on any plate impinges forcibly on the lower corrugated surface of the plate immediately above. The vapours flow over the corrugated surface to the circumference, where they strike against an annular baffle, any liquid which is separated passing, together with the residue of the liquor to be concentrated, down to the next lower heated plate.—J. S. G. T.

Concentrating or drying liquids; Process for —. A. Friedländer, Berlin-Halensee. Ger. Pat. 316,489, 3.9.18.

SUBSTANCES which swell on wetting, e.g., glue, are formed into plates, rods, etc., upon a skeleton frame, and these frames are supported parallel to one another in the liquid to be concentrated with so much space separating them that when the material swells adjacent frames do not touch each other or the walls of the chamber. The concentrated liquid may be drawn off, or the plates may be withdrawn and the thickened mass adhering to them removed mechanically.—J. S. G. T.

Fractionation of gaseous mixtures by partial condensation due to cooling under pressure. Ges. für Lindes Eismaschinen A.-G., Höllriegelskreuth. Ger. Pat. 316,343, 5.2.18.

THE choking of the fractionating apparatus is prevented by liquefying the solid portion of the solid and liquid fraction already separated from the gas prior to relieving the pressure. For this purpose heat exchange by counter-current is effected with the stream of gas to be fractionated.—J. S. G. T.

Filling material for absorption and reaction towers; Hollow bodies for use as —. V. Zieren, Berlin-Friedenau. Ger. Pat. 316,497, 19.12.18.

A NUMBER of rings of different angular patterns are arranged one upon another, and so joined that they form a coherent body, in which the component elements of similar pattern are arranged parallel to one another. Alternatively, rings of the same angular pattern may be used, but with the angles of the rings out of alinement in vertical series. The rings are composed of wire, either single or plaited, or may be cut from a tube and suitably shaped by notching and bending.—J. S. G. T.

Collecting and washing salts; Apparatus for —. H. A. Schmidt, Würzen. Ger. Pat. 316,702, 20.10.18.

By means of a movable mechanical device a number of stationary suction-filter vessels can be consecutively washed and the salt collected and conveyed to the next filter vessel of the series.—J. S. G. T.

Electrical heater for vapours or conducting gases. Allgem. Elektrizitäts-Ges., Berlin. Ger. Pat. 317,302, 8.5.18.

THE gas or vapour is itself used as heating resistance, the heater consisting of a number of parallel insulated pipes connecting the supply pipe for the gas with the delivery pipe. Insulated electrodes are introduced within the insulated pipes, and the electric current passes from these electrodes through the gas or vapour. The device is best operated with high tension current, and can be employed, for example, as a steam superheater in conjunction with an electrical steam boiler.—J. S. G. T.

Protecting apparatus and vessels used in chemical industry against the action of chemicals; Method of —. F. Schüller, Frankfurt. Ger. Pat. 318,033, 14.9.18.

A PROTECTIVE coating is formed of a number of thin

layers of stoneware alternating with layers of silicate or thin layers of glass. The first layer of stoneware is reinforced with metal insertions.

—J. S. G. T.

Prevention of frothing; Apparatus for —. A. Redlich, Vienna. Ger. Pat. 318,478, 26.9.18. Int. Conv., 10.10.17.

A NUMBER of chambers are in a circle around and carried by a shaft which rotates within the space where frothing may occur. The chambers are open only in the direction of rotation, and are each provided with a drainage tube for liquid resulting from bursting of the bubbles constituting the froth.

—J. S. G. T.

Grinding, mixing, and like machines; Scrapers for use in —. O. Shaw, Stockport, and F. Shaw and Co., Ltd., Bradford. Eng. Pat. 140,483, 30.9.18. (Appl. 15,845/18.)

Washing coal, coke, sand, and other materials; Apparatus for —. J. H. Harrison, Gateshead. Eng. Pat. 140,616, 15.4.19. (Appl. 9639/19.)

Purifying liquids [soiled lubricating oils] by sifting, depositing, and overflowing action; Apparatus for —. A. E. Lienart, Brussels. Eng. Pat. 140,677, 30.6.19. (Appl. 16,383/19.) Int. Conv., 10.3.19.

Furnaces; Means for consuming smoke in —. C. H. Halt, Indianapolis, Ind., U.S.A. Eng. Pat. 140,859, 2.1.19. (Appl. 162/19.)

Centrifugal apparatus with planetary movement. W. Mauss, Johannesburg. Eng. Pat. 140,962, 15.8.19. (Appl. 20,118/19.)

Emptying the contents of bins into furnaces or the like; Devices for —. B. E. D. Kilburn, London. From Sulzer Frères, Winterthur, Switzerland. Eng. Pat. 140,963, 20.8.19. (Appl. 20,458/19.)

Tunnel kilns. G. H. Benjamin, New York. Eng. Pat. 140,578, 6.3.19. (Appl. 5605/19.)

SEE U.S. Pat. 1,292,568 of 1919; J., 1919, 313 A.

Furnaces. A. Smallwood, London. U.S. Pats. 1,335,202-4, 30.3.20. Appl., 31.7.18.

SEE Eng. Pats. 125,744, 125,224, and 125,515 of 1918; J., 1919, 489 A, 372 A, 347 A.

Evacuating gases from vessels; Arrangement for —. H. Gerdien, Assignor to Siemens u. Halske A.-G., Berlin. U.S. Pat. 1,335,829, 6.4.20. Appl., 6.10.15.

SEE Eng. Pat. 14,918 of 1915; J., 1916, 101.

Drying organic materials. Ger. Pat. 315,497. See IIB.

Electro-osmotic process. Eng. Pat. 135,817. See XI.

Electro-osmotic dehydration. Ger. Pats. 316,444 and 316,494-6. See XI.

Electro-osmotic electrode. Ger. Pat. 316,593. See XI.

Displacement of liquids. Ger. Pats. 305,512 and 307,701-2. See XI.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Banded bituminous coal; Behaviour of the constituents of — on coking. Studies in the composition of coal. R. Lessing. Chem. Soc. Trans., 1920, 117, 247-256.

COKING tests were carried out on samples of fusain, durain, clarain, and vitrain (cf. J., 1919, 452 A,

614A) in an apparatus previously described (J., 1912, 465, 471), at 900° C. with a heating period of 7 min. and at 600° for 5 min. Fusain showed no outward change in appearance after coking, and had no tendency to cohere, the residue being a powder. Durain had a little greater tendency to cohere than fusain, but the particles retained their angular shape and form. Clarain showed considerable fusion and merging of particles. At 900° C. most of the fine and medium-sized particles lost their identity almost completely. The vitrain particles were well sintered and showed rounding of the angular edges, but the consolidation of particles did not go so far as with clarain. The coke specimens from vitrain were of the "mushroom" type. At 900° C. the free carbon formed with durain was considerably higher than with clarain and vitrain. On the other hand, at 600° C. no carbon was produced from durain, whilst the amounts from clarain and vitrain were only slightly reduced. The gas yields from clarain and vitrain were almost equal, and greater than that from durain. This seems to indicate a considerable difference in the chemical nature of the primary decomposition products of durain on the one side and of clarain and vitrain on the other.—W. P.

Banded bituminous coal; Mineral constituents of —. Studies in the composition of coal. R. Lessing. Chem. Soc. Trans., 1920, 117, 256—265 (cf. ante).

The peculiar behaviour on carbonisation of fusain, durain, clarain, and vitrain suggested that the results were influenced or accentuated by the catalytic effect of their mineral components. Considerable differences were found in the composition of the ashes from the four constituents. A large proportion of lime and soluble matter was found in fusain, and its presence was probably due to infiltration of calcium salts; the lime appears to be present in fusain as calcium carbonate. The thin veins of white mineral found along the cleavage planes contained 40—45% CaCO₃. The composition of the durain ash was comparatively simple, the ash consisting to the extent of 93% of alumina and silica. The composition of the ashes of clarain and vitrain suggest that they represent mainly the remainder of the original plant ashes.—W. P.

Coal; Action of — upon a photographic plate. E. Sinkinson. Chem. Soc. Trans., 1920, 117, 165—170.

The action of coal upon a photographic plate in the dark (cf. J., 1913, 969; 1918, 262A; 1919, 452A) depends upon the presence of oxygen. A sample of coal saturated with oxygen had less effect than an untreated sample, indicating that the absorption of oxygen is part of the mechanism of the action. Coals which had been heated above 500°—530° C. no longer had any action on a photographic plate. It is concluded that the ingredient causing the effect on a photographic plate in the dark is to be found in that portion of the coal which is extracted by pyridine, other than the resin (J., 1919, 752A).

—W. P.

Coal; Effect of excessive moisture in —. A. H. Thwaite. Coke Oven Managers' Assoc., 13.3.20. Gas World, 1920, 72, Coking Sect., 38—39.

The optimum moisture content for coal to be carbonised is given as 8—10%. The drainage of the washed coal would be considerably assisted if large lumps of good coal were crushed separately from inferior coal to a size from 2 in. cube downwards. From results obtained by Bone and Mellor it is estimated that 924 cu. ft. of gas is required to evaporate each 1.0% of water in a ton of coal above 80%. Excessive moisture leads to damage of the oven walls, and an increased carbonising period of

at least 2 hrs. for every 2% moisture above 10% is necessary. As regards the by-products, excessive moisture imposes heavy duties on the exhaustors, condensers, and (in the case of an indirect ammonia plant) the stills, which have to treat a weaker liquor than otherwise. On direct ammonia plants the effect is more serious, as all moisture from the coal is carried along with the gas, making it very difficult to maintain the necessary temperature for heating the ovens.—A. G.

Moisture in coals, etc.; Determining —. A. R. Myhill. Gas J., 1920, 150, 21.

The method comprises the distillation of 200 c.c. of water-free benzol, toluol, or xylol with 100 g. of coal, or other substance to be tested, up to 110° C. or over, the distillate being caught in a graduated receiver.—A. G.

Water-gas; Heat conservation and —. E. G. Stewart. London and S. Distr. Jun. Gas Assoc., 26.3.20. Gas J., 1920, 149, 750—755.

The factors governing the efficiency of a water-gas plant are discussed and it is pointed out that a counter-current of steam possesses a distinct advantage, leading to good reduction and the provision of a cool top zone. With the blow waste gases at 1800° F. (980° C.) the efficiency of the plant is given as 58%, whilst with the gases at 1500° F. (815° C.) and the carbon burning to 90% CO during the air blow, the thermal efficiency may be only 34%. Working results of a large carburetted water-gas plant at Fulham are given, together with a description of a waste-heat boiler of special design and of the economies effected by its use.—A. G.

Gas; Influence of impurities in — on the corrosion of meters and the blockage of service pipes. A. R. Myhill. Gas World, 1920, 72, 265.

DEPOSITS caused by impurities have been found to consist of iron rust, free sulphuric acid, iron sulphates, thiocyanates, ferrocyanides, pyridine and ammonium compounds, and free sulphur. Corrosion is facilitated by the presence of air and moisture and of cyanogen compounds and sulphide. An insoluble iron-ammonium-hydrogen ferrocyanide is produced when ammonia, ferric oxide, iron, and hydrocyanic acid react together, and pyridine forms a similar compound. Pyridine can be washed out of the gas by the use of cold water in the finishing scrubber, and the Williams process for the removal of cyanogen is recommended, ammonium thiocyanate being recovered.—A. G.

Benzol; Estimation of — in coke-oven gas and scrubbing oil. L. Shuttleworth. Gas World, 1920, 72, Coking Sect., 43.

DETAILS are given of the determination of benzol in coke-oven gas by absorption in petroleum oil and of the benzol in the oil by means of fractionation.—A. G.

Hydrocarbons; Analysis of — by the aid of bacteria. J. Tausz and M. Peter. Zentr. Bakt. u. Parasit., II. Abt., 1919, 49, 497—554. Chem. Zentr., 1920, 91, II., 261.

THE separation of paraffins from naphthenes can be effected by means of *B. aliphaticum*, *B. aliphaticum liquefaciens*, and the paraffin bacterium, which are described; they were isolated from garden mould by culture in organic and inorganic media containing *n*-hexane, cyclohexane, or paraffin oil. Paraffin bacteria are without action on naphthenes, henzenoid hydrocarbons, and some paraffins (*n*-hexane and *n*-octane), but attack higher paraffins such as hexadecane, triacontane, and tetratriacontane. The other two species are inert towards cyclic hydrocarbons and hexylene, but attack paraffins and *n*-caprylene and hexadecylene.

Destruction of the reactive hydrocarbons is complete even in the presence of hydrocarbons which are not attacked. The presence of very small proportions of aliphatic hydrocarbons in natural naphthenes or of impurity in artificial specimens is shown by the clouding due to bacterial growth of media containing the hydrocarbon under examination. The method can be used for the detection of paraffins in crude oils and their products and for the isolation of pure naphthenes. As regards enzymes urease was absent; diffusion lipase and proteolytic enzymes were shown in the case of *B. aliphaticum* and the paraffin bacterium, diastase by paraffin bacterium and *B. aliphaticum*, and catalase by both the aliphaticum species. New constants for hydrocarbons purified by means of the bacterial treatment are: 1,3-dimethylcyclohexane, b.p., 118°–120° C., sp. gr. at 20°/4° C., 0.771; $n_D^{20} = 1.42558$; 1,3,4-trimethylcyclohexane, b.p., 139°–140° C., sp. gr. at 20°/4° C., 0.789; $n_D^{20} = 1.4330$.—A. E. D.

Ceresin; Algebraic method for the detection of adulteration of — with paraffin. H. Smelkus. Chem.-Zeit., 1920, 44, 273–275, 286–288.

HOLDE's method (J., 1914, 242) consists in fractional precipitation from chloroform by means of alcohol; the paraffin can be detected by the diminished refractive index of the fraction in which it is concentrated. Equations and a graphical method are developed, for which the original should be consulted.—A. E. D.

Waste products in the petroleum industry; Working up of —. E. W. Albrecht. Chem.-Zeit., 1920, 44, 282.

THE thick acid tar produced in the treatment of lubricating oils with sulphuric acid is washed until free from acid. The residue is mixed with Trinidad asphalt and used for paving. The acid liquor is concentrated. The thin acid tar resulting from the treatment of solar oil with oleum is washed similarly and the acid recovered. The dilute alkali wash always contains emulsified oil. This is recovered by neutralising the alkali.—A. E. D.

PATENTS.

Peat; Process for dehydrating —. C. Bouillon, Paris. Eng. Pat. 140,112, 17.1.18. (Appl. 987/18.)

PEAT, preferably finely divided, is treated with a cold dilute solution of calcium chloride or other substance capable of coagulating blood. (Reference is directed to Eng. Pats. 9911 of 1907, and 3367 and 25,385 of 1912; J., 1908, 553; 1913, 277, 1149.)

—A. G.

Peat and the like; Method and apparatus for treating [dehydrating] —. H. H. Hindshaw, Ann Arbor, Mich. U.S. Pat. 1,334,492, 23.3.20. Appl., 3.7.18.

PEAT is conveyed through a chamber, partly cylindrical and partly conical, by means of a screw, which breaks up the peat in the cylindrical part and compresses it in the conical part. The peat then passes to another chamber, where it is subjected to similar treatment, but under a vacuum to remove the air that was released from the air cells by the first treatment.—B. M. V.

Peat dryer. W. S. Jackson, Toronto, Canada. U.S. Pat. 1,334,495, 23.3.20. Appl., 6.5.18.

A HOLLOW shaft carrying radial agitators and a

hollow worm are rotated in a jacketed cylinder, through which the peat is passed. Steam is supplied to the jacket, to the worm, and to the shaft.

—B. M. V.

Peat; Process for treating —. R. Gruhl, Charlottenburg. Ger. Pat. 310,111, 23.8.17.

PEAT is rendered water-resistant by treatment with hydrochloric or nitric acid, chlorine, or acid salts of mineral acids, or by treatment first with chlorine and then with nitric or hydrochloric acid, or with a mixture of these acids. Moulded peat may be treated with dilute nitric acid and then heated, either with or without pressure. The gelatinous constituents of the peat are changed into substances which do not swell in water and are easily washed out; the washed peat may be moulded with or without pressure. After drying the treated peat has completely lost its swelling power and almost completely its water-absorbing power.—B. V. S.

Combustible mass of kieselguhr soaked with spirit. H. von Schütz, Berlin-Wilmersdorf. Ger. Pat. 316,346, 31.10.17.

KIESELGUHR which has been purified by successive washing, centrifuging, extraction with acids, washing, and calcining will absorb up to four times its weight of alcohol.—D. F. T.

Light-coke product and method of making same. Method of utilising fuel. H. Rodman, Edgewood, Pa., Assignor to Rodman Chemical Co., East Pittsburgh, Pa. U.S. Pats. 1,334,404 and 1,334,405, 23.3.20. Appl., 22.6.15.

CRUSHED coking coal is fed on to a heated tumbling mass of separate non-viscous particles, the mass being of sufficient size relatively to the amount of coal fed in to insure a separation of the coal during the coking process, so that the coal is subjected to a tumbling action whilst in the viscous state.

Gases; Production of rich — by means of petroleum residues and apparatus therefor. Soc. de Chimie et Catalyse Industrielles, Paris. Eng. Pat. 140,128, 15.10.18. (Appl. 16,820/18.) Int. Conv., 20.2.18.

PETROLEUM residues are vaporised and the vapours passed through retorts at 500°–600° C., containing a metallic catalyst, e.g., iron or copper. The gases thus obtained are used to enrich blue water-gas or other poor gas, whilst the liquid hydrocarbons which distil up to 150° C. may be used as a motor fuel.—A. G.

Gas-cleaning device. J. Keith and D. B. Bain, London. Eng. Pat. 140,170, 12.2.19. (Appl. 3405/19.)

THE gas (producer-gas, blast-furnace gas, or the like) passes through a casing provided with two revolving paddle wheels in series, on one of which water is caused to play. The tar is thus condensed, and the tar-water mixture is separated from the gas partly by the action of the second paddle-wheel and partly by a centrifugal fan in a separate chamber.—A. G.

Ammonia; Method for recovering — in gasification processes. Bergmann-Elektrizitäts-Werke A.-G., Berlin. Ger. Pat. 298,891, 21.3.16.

A high yield of ammonia is obtained by mixing steam with the air required for combustion, the supply of steam and air being adjusted to suit the nature of the material being gasified and the size and type of gas producer.—W. J. W.

Producer-gas plants; Obtaining by-products from —. J. Pintsch A.-G., Berlin. Ger. Pat. 316,500, 15.9.17.

THE hot producer-gas, after passage through an

apparatus in which it preheats the air supply to the producers, is cooled and scrubbed free from ammonia, the ammoniacal liquor obtained is used as the cooling medium in the coolers for the gas from the producers, and then, while warm, is employed to enrich the air supply with water vapour and ammonia. The air supply, before it is led into the producers, is freed from ammonia, and is completely saturated with water vapour.—L. A. C.

Gasoline; Apparatus for manufacture of —. R. F. Bacon and B. T. Brooks, Pittsburgh, Pa., and C. W. Clark, Chicago, Ill., Assignors to Gulf Refining Co., Pittsburgh, Pa. U.S. Pat. 1,334,731, 23.3.20. Appl., 1.2.15.

AN apparatus for cracking and distilling petroleum oils under pressure consists of a receptacle for the oil and means for heating the oil to the temperature of distillation, for feeding the oil under pressure, and for maintaining the pressure at 60—300 lb. per sq. in. The lower settling zone of the receptacle is in free communication with the upper cracking and distilling zone, so as to remove continuously by gravity the particles of coke and tar produced.—J. W. D.

Gas generators or the like; Apparatus for agitating the fuel in — and means for operating the same. G. H. Bentley and E. G. Appleby, London. Eng. Pat. 140,891, 13.3.19. (Appl. 6336/19.)

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Dry distillation or drying of organic materials [wood, waste cellulose lyes, etc.]; Process and furnace for the —. Aktiebolaget Cellulosa, Stockholm, and G. F. Magnuson, Gelle, Sweden. Ger. Pat. 315,497, 11.1.17. Int. Conv., 1.12.16.

THE gases evolved during drying or dry distillation are utilised to transmit heat from a heating chamber to the material to be treated (organic material either alone or mixed with inorganic material). The heating chamber is arranged between two treatment chambers, and injectors or similar devices are provided to effect the desired circulation of the gases, which pass from above downwards over the material to be treated. A pressure chamber may be arranged above the heating chamber and the treatment chambers, and is provided with suitable openings whereby the hot gases may be forced into the upper part of the treatment chambers.—J. S. G. T.

Vacuum tubes. N. V. Philip's Gloeilampenfabrieken, G. Holst, and E. Costerhuis, Eindhoven, Holland. Eng. Pat. 139,860, 5.2.19. (Appl. 2879/19.)

THE gas in a vacuum tube is renewed automatically or added to by means of a device, comprising a gas reservoir containing two electrodes, or a heating filament or like device for heating the gas; the reservoir is connected to one end of a U-tube containing mercury, the other end being closed. The U-tube is connected to the vacuum tube

through a porous plug in a branch tube, the latter being connected to the U-tube at a point between the ends.—B. N.

Electrical discharge tube. C. E. Green and J. H. Clough, Schenectady, N.Y., Assignors to General Electric Co. U.S. Pat. 1,334,150, 16.3.20. Appl., 11.7.16.

AN electrical discharge device comprises an envelope containing a rare gas, a magnesium cathode, and an anode.—B. N.

Cathode for vapour-filled or gas-filled discharge tubes. W. Gormershausen, Berlin-Schöneberg, and A. Partzsch, Berlin-Karlshorst. Ger. Pat. 315,990, 8.7.17.

THE cathode is constituted of two parts. The one is connected with the source of current, but does not furnish any electronic emission, this being derived from a second metal of lower vaporising temperature placed in the immediate neighbourhood but insulated from the first. The vaporisable metal may be, for example, iron, nickel, copper, or aluminium, and the cathode itself platinum.

III.—TAR AND TAR PRODUCTS.

Benzol in gas etc. Shuttleworth. See IIa.

Hydrocarbons. Tausz and Peter. See IIa.

PATENTS.

Wood tar or the like [lignite or peat tar]; Extraction of higher fatty acids and other organic acids from —. E. Börnstein, Berlin. Ger. Pat. 315,417, 6.9.18. Addition to 314,358.

TAR from lignite, peat, and the like is treated as described in the chief patent (J., 1920, 57 A). The oil obtained by distilling lignite tar at 220°—250° C. with superheated steam is freed from pitch, treated with an alkali carbonate, and washed with water. A portion of the arachidic acid separates as an acid salt and is removed by filtration, neutral oils are extracted from the filtrate by treatment with a light oil, and higher fatty acids are then precipitated by the addition of a mineral acid and distilled at 15 mm. Palmitic, oleic, and arachidic acids distil above 190° C.; the tars mentioned do not yield abietic acid.—L. A. C.

Oil-like products; Process for obtaining neutral —. M. Wendriner, Berlin. Ger. Pat. 316,998, 13.6.14.

THE saturated wash liquors obtained by extracting crude benzene and tar oils with alkalis and sul-

phuric acid respectively are mixed in equivalent proportions. The neutral oily mixture (pyridine and phenols) so obtained may be purified by fractionation, filtration, etc., or the wash liquors may be separately purified before mixing.—B. V. S.

αβ-Dibromotetrahydronaphthalene and Δ¹-dihydronaphthalene; Production of —. J. von Braun. Ger. Pat. 316,218, 27.8.18.

TETRAHYDRONAPHTHALENE is treated with the calculated quantity of bromine at 100°–140° C., and the resulting αβ-dibromotetrahydronaphthalene (m. p. 69° C.) is submitted to the action of magnesium and ether or of tin and alcohol with formation of Δ¹-dihydronaphthalene, b.p. 85° C. at 15 mm., solidif. pt. –8° C.—D. F. T.

Bituminous material [pitch or the like, in filamentary form]; Manufacture of —. H. Wade, London. From The Barrett Co., New York. Eng. Pat. 133,466, 15.10.18. (Appl. 16,847/18.)

Tar soap. Ger. Pat. 316,258. See XII.

IV.—COLOURING MATTERS AND DYES.

Phthaleins and fluorans. M. Copisarow. Chem. Soc. Trans., 1920, 117, 209–218.

IN most cases the formation of phthaleins is accompanied by the production of substances belonging to the o-ketonic acid, hydroxyanthraquinone, and fluoran series. Zinc chloride as a condensing agent is more efficient than concentrated sulphuric acid, giving a 46% yield of phenolphthalein, against 26% with the acid, and 59.3% yield of α-naphtholphthalein, compared with 22.4% with sulphuric acid. The zinc chloride is most efficient when prepared by evaporating to dryness a faintly acid solution of the salt. Hydrogen chloride as a condensing agent favours the formation of hydroxyanthraquinones and phthaleins, but it is not very effective unless used in conjunction with zinc chloride. Boric acid used with sulphuric acid improves the yield of phenolphthalein to 31%, 8% of fluoran and 5% of hydroxyanthraquinones being produced at the same time. o-Cresolphthalein was obtained in 46% yield by the zinc chloride condensation, but p-cresol gave only a 26% yield of 2,7-dimethylfluoran and 2.5% of 4-hydroxy-1-methylantraquinone. Similarly β-naphthol in contradistinction to α-naphthol gave no phthalein, but only a 12% yield of β-naphthylfluoran. These facts provide evidence that the hydroxyl group in the phthaleins takes up the para position to the central C atom of the phthaloyl group.—G. F. M.

PATENT.

Tetrakisazo dyes; Blue —. J. Dedichen, Berlin-Halensee, Germany, Assignor to The Chemical Foundation, Inc. U.S. Pat. 1,319,852, 28.10.19. Appl., 6.11.16.

See Eng. Pat. 101,967 of 1916; J., 1917, 1174.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Nitrocellulose from wood pulp. Woodbridge. See XXII.

Finger-prints. Mitchell. See XXIII.

PATENTS.

Wool and allied materials in the raw state or at any of the various stages of manufacture; Treatment for cleansing [scouring] of —. T. Hollis and A. Woodmansey, Leeds. Eng. Pat. 137,747, 14.6.19. (Appl. 15,007/19.)

THE material is cleansed, either cold or at a tem-

perature not exceeding 90° F. (32° C.), in open machines by means of oil or oils (mineral, fatty, or coal tar oils), e.g., petroleum fractions not lighter than kerosene, olive oil or other similar non-drying oils, re-distilled creosote or residual oils such as anthracene oil or "green" oil, or oils or fatty acids modified by sulphonation, by amidation, by the addition of alkali, of soap, glycerin, or other emulsifying agents. The media may be used separately, or in any desired combination, or in any sequence; water may be present in small quantities according to the media. The media are removed, according to their properties, by means of soluble oils, mild alkalis, or weak soap solutions. Where fibrous material has been treated with soluble oil or soluble oil solutions or with modified oils, it may be passed forward for carding or preparing with a percentage of oil or solution still remaining, which, however, may be easily removed by mild alkaline treatment in the backwater (backwashing) or in later operations of manufacture.—L. L. L.

Lubricant for use in weaving, braiding, rope-making, and the like. L. Minton, Manchester. Eng. Pat. 140,174, 19.2.19. (Appl. 4114/19.)

A MIXTURE of ground mica and powdered aluminium, together with tallow, soap, etc., or with water or oil, is used as a lubricant for the yarn in weaving and similar machines, particularly in the manufacture of lace curtains.—J. F. B.

Fibre from typha seeds; Treatment of — for use in manufacturing textiles. Jata-Werk für pflanzliche Füllstoffe G.m.b.H., Dresden. Ger. Pat. 305,578, 28.9.17.

THE fibres or hairs from typha seeds are hardened and made suitable for spinning by treatment for one or more hours in a 15% solution of sodium chloride boiling under about 1 atm.—L. A. C.

Textile fibres; Method for the preparation of —. Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pat. 316,414, 30.11.18.

CERTAIN vegetable juices are applied to the treatment of textile fibres for the removal of the substances which are susceptible to decomposition by enzymes. Of the rhizomes, roots, and tubers of value for the above purpose the potato is typical; typha fibres, for example, may be submitted to the amylolytic and proteolytic action of the juice of the potato at 40°–50° C.—D. F. T.

Textile fibres from Malva crispa and Lavatera trimestris. A. Hammer, Berlin. Ger. Pats. (A) 316,951 and (B) 316,952, 3.9.18.

(A) THE roots of *Malva crispa* are subjected to a retting process, and the fibres are stripped by breaking the woody portions. The root fibres are finer and softer than the stem fibres. (B) The bast of *Lavatera trimestris* or *Malope grandiflora* is treated by the cold or hot water retting system or by boiling and subsequent breaking or spraying with jets of water, whereby a long flax-like fibre is obtained. By further resolution by means of chemicals, a fibre having more of the character of cotton is produced.—J. F. B.

Mulberry bark; Manufacture of fine spinning fibres from —. G. Mark, Bretnig. Ger. Pat. 317,043, 15.9.18.

FIBRES isolated in the usual manner are caused to shrink and become curly by the action of strong alkalis. The product is pliable and very fine, and is easily spun by the methods employed for cotton or wool spinning.—J. F. B.

Soda-cellulose, particularly wood-cellulose; Process of producing —. E. L. Rinman, Djursholm, Sweden. U.S. Pat. 1,319,360, 21.10.19. Appl., 23.5.18.

THE raw material is boiled with caustic soda lye

(60 g. per litre) in presence of a contact substance, which is insoluble in caustic soda lye and furthers reduction, e.g., mercury.

Cymene obtained in sulphite-cellulose process; Method of recovering —. L. Akerblom, Stockholm. U.S. Pat. 1,333,694, 16.3.20. Appl., 11.2.18.

THE gases from the cellulose digester are led into a receptacle containing acid for a subsequent digestion; the greater portion of this acid is then tapped off from the lower end of the receptacle and the remainder, together with the cymene floating on the liquor, is conducted into a second receptacle. The level of liquid in the latter is then raised by introducing a liquid heavier than cymene, so that the cymene is forced up into a narrow portion of the receptacle from which it is drawn off.—J. F. B.

Adhesive for articles made of cellulose derivatives. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 317,412, 26.10.17.

THE dimethyl, diethyl, or β -methyl ester of adipic acid may be employed as an adhesive for articles made of cellulose derivatives.—L. A. C.

Counter-board and process of making same. A. L. Clapp, Marblehead, Mass., Assignor to The Metalite Co., Amesbury, Mass. U.S. Pat. 1,332,541, 2.3.20. Appl., 28.6.17.

FIBROUS cellulose is treated with alkali without the application of heat; the stock thus obtained is formed into sheets, and the sheets are dried.

—J. F. B.

Paper; Process of manufacturing —. A. Imaoka, Tokyo, Japan. U.S. Pat. 1,333,255, 9.3.20. Appl., 9.7.19.

THE outer bark of abaca is boiled in a solution of caustic alkali, whereby the non-fibrous part of the bark is caused to gelatinise, and the gelatin-like substance thus obtained is caused to cover the fibres for the manufacture of paper.—J. F. B.

Paper, boards, and paper textiles; Process for sizing and waterproofing —. P. E. Altmann, Dresden-Tolkewitz. Ger. Pat. 304,205, 2.8.17.

THE material is impregnated with a mixture of saponified beeswax, water-soluble oils, and talc, and the sizing agent is fixed by means of alum solution.

—J. F. B.

Emulsions for sizing paper; Manufacture of —. G. Muth, Nuremberg. Ger. Pat. 316,345, 27.6.16.

COUMARONE resin, or a similar coal-tar resin, is emulsified with an aqueous solution of a vegetable or animal glue or a similar colloid, and a solution of an aluminium salt is added; casein may be employed as the colloid if it is first converted to the water-soluble form.—L. A. C.

Impregnating paper and the like; Machines for —. C. W. Mayer, Rochester, N.Y., U.S.A. Eng. Pat. 140,861, 6.1.19. (Appl. 399/19.)

Paper felt; Manufacture of — for roofing or the like. H. Wade, London. From The Barrett Co., New York. Eng. Pat. 127,994, 12.6.18. (Appl. 9693/18.)

Distillation or drying. Ger. Pat. 315,497. See IIa.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Bleaching apparatus and the like. J. R. Fish, Bolton. Eng. Pat. 137,947, 5.3.19. (Appl. 5429/19.)

MECHANISM outside and inside the kier is provided

to give to a hollow plaiting machine arm, at the extremities of which are rollers, a rotation about an axis for spreading the cloth, and a reciprocating motion so as to cause it to plait the fabric radially. The rollers at the ends of the plaiting machine arms draw the fabric into the kier. By means of a differential gear the combined motions are made to take place simultaneously.—L. L. L.

Dyeing machine; Automatic yarn hank —. Textilmaschinen Fabrik A.-G., Zurich, Switzerland. Eng. Pat. 128,586, 20.6.19. (Appl. 15,611/19.) Int. Conv., 20.6.18.

TWO connected frames are movable intermittently, simultaneously, and in the same direction along the side walls of the dyeing trough, which are toothed on their upper edges. Forks are provided for lifting the hank-carrying rods from the toothed side walls and for carrying them through the trough. The apparatus is practically free from machine parts above the dyeing trough, and consequently the injurious effect of the vapours from the bath is reduced to a minimum.—L. L. L.

Dyeing or similarly treating yarns in the form of hanks, skeins or bundles; Machines for —. A. Ashworth, Manchester. Eng. Pat. 137,980, 1.5.19. (Appl. 10,822/19.)

AN improved form of the machine described in Eng. Pat. 113,575 (this J., 1918, 204 A) comprises a single rectangular tank without any central compartment or division. The dye liquor is pumped directly into the tank, and passes through a wire gauze screen to ensure even distribution. The skeins or bundles of material are laid full length across the tank in the direction of the flow of liquor. The dry yarn is compressed by a lid fitting the tank with a sliding fit and having its upper edges bevelled, to receive a rope of cotton or other packing upon which an angle iron frame is clamped.—L. L. L.

Fibre-treating machine. H. M. Dudley, Philadelphia, Pa. U.S. Pat. 1,328,987, 27.1.20. Appl., 4.12.18.

A FIBRE chamber is provided with removable foraminous bottom and top plates, and with a spider follower, which abuts against the top plate and moves it with respect to the bottom plate. Means are provided for forcing liquid in either direction through the device.—L. L. L.

Dyeing machine. Hosiery-dyeing machine. Fabric-treating device. Textile-treating device. H. M. Dudley, Philadelphia, Pa. U.S. Pats. (A) 1,334,526, (B) 1,334,527, (C) 1,334,528, and (D) 1,334,529, 23.3.20. Appl., (A) 20.11.17, (B) 5.6.18, (C) 22.1.19, and (D) 25.2.19. (Cf. J., 1920, 228 A.)

(A) THE machine consists of a receptacle in which are hollow perforated spindles on which fibres may be wound. The fibres can be compressed on the spindles by means of removable bars, and means are provided for forcing a liquid through the spindles and so through the fibre, through the fibre into the hollow spindles, and through the whole machine. (B) A cylindrical machine contains a series of reels placed end to end and formed by a perforated spindle on which are spaced perforated discs. The fibres are wound on these reels and covered with perforated plates. A liquid can be forced through the spindle and fibre in either direction. (C) The fabrics to be treated are contained in a chamber which can be revolved at varying rates. A liquid can be forced through the fabric chamber. (D) The fibre is wound on beams in a dyeing machine. Means are provided for passing a liquid through the series of beams in outward and longitudinal directions simultaneously.—A. J. H.

Fibrous material; Method of colouring —. C. H. Dennison, Wollaston, Mass., Assignor to American Rubber Co. U.S. Pat. 1,332,974, 9.3.20. Appl., 10.8.16.

THE fibrous material is subjected to the action of a solution of cadmium chloride and of a polysulphide of an alkaline-earth metal, and is finally treated with a vulcanisable plastic compound.

—J. F. B.

Fibrous material; Method of colouring —. W. A. Gibbons, Flushing, N.Y., Assignor to American Rubber Co. U.S. Pat. 1,332,982, 9.3.20. Appl., 10.8.16.

FIBROUS material is coloured and rubberised by dipping it in a solution of potassium antimony tartrate and a solution of ammonium sulphide, whereby antimony sulphide is formed directly in or upon the fibres, and the material is then coated with a vulcanisable plastic compound.—J. F. B.

Dyes; Means of fastening — in material and waterproofing same. H. Sharp, Leeds. Eng. Pat. 140,222, 3.4.19. (Appl. 8360/19.)

DYED fabrics are treated successively with solutions of alum, of paraffin wax, rosin, and curd soap, and of Epsom salts (magnesium sulphate).

—A. J. H.

Textile fabrics; Finishing or lustring —. J. B. Lomax, Furness Vale. Eng. Pat. 137,710, 15.4.19. (Appl. 9532/19.)

THE fabrics are passed through a Schreiner calendaring machine under much heavier pressure and at a higher temperature than is usually employed, the Schreiner calender roll being heated to a blue heat or to as high a temperature as the cloth will withstand without injury. Whilst still hot and under tension the fabric is treated on one or both sides with a finishing liquor, composed preferably of a boiling solution of alizarin oil. The fabric is wound on rollers and left in the wet state for 10–12 hours, and then stretched and stentered.

—L. L. L.

Finishing fabrics. J. H. Wrigley, Manchester, and A. B. Henshilwood, Bradford. Eng. Pat. 137,948, 6.3.19. (Appl. 5538/19.)

SHEET rubber or rubber-covered fabric or other elastic material is wound together with the fabric to be treated, so that it forms a layer between adjacent coils of the fabric. When such a roll is treated in a beetling machine, although the more prominent fibres, or surfaces, receive the bulk of the pressure, this is transmitted by the elastic material to the less prominent surfaces, and a more uniform finish is obtained without undesirable "watered" or "moirée" effects.—L. L. L.

Beetling and treatment of fabrics. J. D. Lumsden, W. R. Mackenzie, E. H. Robinson, and M. Fort, Almondbank, Perthshire. Eng. Pat. 137,968, 5.4.19. (Appl. 8616/19.)

THE beetling properties of cotton, linen, union, or other fabrics composed mainly or wholly of vegetable fibres are improved by removing oils, fats, waxes, or resinous products from the fabrics. For this purpose the material is subjected to a dry-cleaning treatment, or a treatment with a volatile solvent. In the case of goods to be bleached the solvent treatment may precede bleaching, thereby ensuring good beetling properties irrespective of the bleaching treatment accorded. This process is particularly useful when applied to the beetle-finishing of coloured bordered goods, and linen and cotton goods generally containing threads which are also often required to withstand bleaching.

—L. L. L.

Bleaching-boiler plant. C. Tütsch, Winterthur, Switzerland. U.S. Pat. 1,335,925, 6.4.20. Appl., 21.9.18.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Ammonia; Catalytic synthesis of —. M. Guichard, Vavon, Cornec, Cantagrel, Stevenson, Apard, and Bourdiol. Bull. Soc. d'Encour., 1920, 132, 71–102.

THE authors have specially studied the characteristics of various catalysts, chiefly the non-alkali metals, which do not demand absolute dryness of the gaseous mixture. The life of catalysts such as iron, cobalt, nickel, tungsten, and molybdenum is greatly extended by admixture with refractory substances, such as magnesia and alumina, and greater activity is secured by using a combination of two metals. Of 400 catalysts examined iron-molybdenum appears to be the most resistant, and to give the highest concentration of ammonia, viz., more than 4% as compared with:—iron, less than 1%; molybdenum, less than 1.5%; nickel, 3%; and cobalt, 3%. The method of preparation is important, and the most satisfactory results are obtained by precipitation of ferric nitrate with ammonium molybdate, ignition, and subsequent reduction. In absence of moisture, uranium gives good results, but its combinations, uranium-cobalt and uranium-molybdenum, are inferior, whilst uranium-nickel is unsatisfactory, and uranium-tungsten almost entirely inactive. The effect of catalytic poisons is briefly discussed. A partial study has been made of the cycle of operations, involving circulation of the compressed gases, heat recovery, absorption of ammonia under pressure, and best arrangement of the furnace.—W. J. W.

Nitrogen and hydrogen mixture; Preparation of — by decomposition of ammonia. R. O. E. Davis and L. B. Olmstead. J. Ind. Eng. Chem., 1920, 12, 316–317.

ANHYDROUS ammonia was decomposed into a mixture of hydrogen and nitrogen ($3H_2:N_2$) by passing it through an electrically-heated tube furnace containing iron turnings or steel wool as catalyst, and subsequently absorbing the undecomposed ammonia. The ammonia remaining in the scrubbed gases rarely exceeded 0.2%. For ordinary operations a yield of 100 cb. ft. per hour of the gaseous mixture was obtained, the temperature being maintained at 675° C. The average period of contact with the catalyst was about 5 secs. When copper is used as catalyst a temperature about 200° C. higher and longer contact are required. (Cf. J. C. S., June.) —C. A. M.

Ammonia and formates; Production of — from cyanides, ferrocyanides, and cyanised briquettes. G. W. Heise and H. E. Foote. J. Ind. Eng. Chem., 1920, 12, 331–336.

IN the hydrolysis of cyanides in an autoclave under varying pressures good yields of ammonia were obtained by steaming under a pressure of 50 lb., and a quantitative yield at 200 lb. pressure. Ferro-

cyanides were hydrolysed more slowly, a maximum yield of 46% being obtained after steaming for 44 hours at a pressure of 300–330 lb. In the case of cyanised briquettes yields of over 90% were obtained by steaming for 30 to 45 mins. at a pressure of 300–330 lb. A temperature of 600° C. was required to obtain good results with steam at atmospheric pressure, whilst with steam at 100 lb. pressure a temperature of 400° C. was satisfactory.

—C. A. M.

Electrolysis of mixed solutions of alkali salts. Phenomena of electrolytic migration. M. H. van Laer. *Rec. Trav. Chim.*, 1920, 39, 301–329.

In the electrolysis of a solution of sodium hydroxide in a diaphragm cell the current yield is small and variable. The electrolysis of a solution of sodium carbonate presents the same fundamental characteristics, and in this case as the electrolysis proceeds the resistance of the cell increases owing to the formation of sodium bicarbonate. The introduction into the solution of an oxy salt of sodium such as the chlorate, sulphate, or nitrate prevents the formation of the bicarbonate, and consequently a cathode liquid very rich in sodium hydroxide can be obtained. The nitrate gives the best result, and the current yield increases with the concentration of the oxy salt. Using this same method with a saturated solution of barium nitrate holding barium carbonate in suspension as anolyte, and a rotating anode, crystals of barium hydroxide were ultimately obtained from the cathode liquid, which at the start was a weak solution of the hydroxide. (*Cf.* J. C. S., ii., 282.)—W. G.

Aluminates; Hydrolysis of alkali — and methods of determining the concentration of hydroxyl ions in concentrated solutions of alkali hydride. R. Fricke. *Z. Elektrochem.*, 1920, 26, 129–151.

THE hydrolysis of alkali aluminates is a time reaction. So-called crystalline alumina is not really crystalline; its properties vary with the age of the product. The ageing of alumina is proportional to the hydroxyl ion concentration of the alkaline solution in equilibrium with it. Aged solutions of alkali aluminates contain considerable quantities of colloidal alumina. The hydroxyl ion concentration of concentrated alkali solutions can be estimated by an electrometric method. (*Cf.* J. C. S., June.)

—J. F. S.

Sulphuric ions; Detection of masked — in complex compounds. P. Job and G. Urbain. *Comptes rend.*, 1920, 170, 843–845.

In complex cobalt compounds the total SO_4 ion present is estimated by precipitation in the usual way as barium sulphate and the free SO_4 ion by precipitation in the cold as benzidine sulphate. The difference gives the masked SO_4 ion present in the complex compound.—W. G.

Hypoiodous acid; Estimation and kinetics of — in acid solution. V. Cofman. *Bull. Soc. Chim.*, 1920, 27, 234–239.

THE fact that hypoiodous acid, but neither free iodine nor any other iodine compound, gives stable iodo compounds almost instantaneously with phenols forms the basis of the following method for the estimation of this acid. To a measured volume of the solution under examination potassium iodide is added, the solution is acidified, if necessary, and titrated with standard thiosulphate. The operation is then repeated, but this time an excess of phenol is added before the potassium iodide. The difference in the amount of iodine found by the two titrations is a measure of the amount of hypoiodous acid present. (*Cf.* J. C. S., ii., 329.)—W. G.

Boric acid; Acidimetric estimation of —. J. A. M. van Liempt. *Rec. Trav. Chim.*, 1920, 39, 358–370.

If a suitable excess of mannitol, glycerol, or hævulose is added to the solution, boric acid may be estimated electrometrically by measuring the hydrogen-ion concentration of the solution after successive additions of standard alkali.—W. G.

Ferrates; Influence of superimposed alternating current on the anodic formation of —. G. Grube and H. Gmelin. *Z. Elektrochem.*, 1920, 26, 153–161.

CONCENTRATED solutions of sodium ferrate may be obtained by electrolysis of a 40% solution of sodium hydroxide at 35° C. in a divided cell using a platinum cathode and an iron anode. The current to be employed is 3.33 amp./sq. dm. direct current with 5.0 amp./sq. dm. alternating current superimposed. (*Cf.* J. C. S., June.)—J. F. S.

Gases; Action of finely divided —. C. Zengheis. *Comptes rend.*, 1920, 170, 883–885.

By passing hydrogen, generated in an external vessel, through filter paper or parchment (as used for dialysers) into solutions of mercuric chloride, potassium chlorate, etc., the author has obtained noticeable reduction of these salts. Similarly carbon dioxide in aqueous solution was reduced to formaldehyde and trioxymethylene. Under somewhat similar conditions certain oxidations can be effected, and nitrogen can be caused to combine with hydrogen in the cold. The author considers that the reactions brought about by gases in their nascent or occluded state are not necessarily due to any excess of free energy possessed by free atoms, but simply to the extremely finely divided state of the gases.—W. G.

Hydrogen; Sorption of — by palladium at low temperatures. J. B. Firth. *Chem. Soc. Trans.*, 1920, 117, 171–183.

AT the temperature of liquid air “active” palladium is “inactive” so far as absorption of hydrogen is concerned, and immersion in liquid air tends to retard the activity when the temperature is allowed to rise once again to the normal. Similar effects were produced after cooling at 0° C. At these low temperatures, however, there is rapid occlusion or “adsorption” of hydrogen. The limiting temperature for absorption or diffusion into the interior of the metal is probably about 0° C.; below this temperature adsorption only occurs, from 0°–150° C. adsorption followed by absorption, and above 150° C. absorption only.—G. F. M.

Absorptive power of sugar charcoal; Effect of heating on the — for sulphur dioxide. R. M. Winter and H. B. Baker. *Chem. Soc. Trans.*, 1920, 117, 319–320.

THE specific gravity of purified sugar charcoal was increased from 1.76 to 1.81 by heating to 900° C. in a muffle furnace for 40 hours, and at the same time the amount of sulphur dioxide capable of being absorbed by 1 grm. increased from 97 c.c. to 288 c.c. —G. F. M.

PATENTS.

Acid plant. E. L. Larison, Anaconda, Mont. U.S. Pat. 1,334,381, 23.3.20. Appl., 10.2.19.

A CHAMBER for use in the manufacture of sulphuric acid consists of interior masonry walls and a lead

sheathing supported by the walls and by a framework, the members of which are also supported by the walls.—A. R. P.

Acetic acid of high concentration; Production of — from gases containing acetic acid vapour. Konsortium für elektrochem. Ind., G.m.b.H., Munich. Ger. Pat. 305,125, 29.6.16.

Gas containing acetic acid vapour is scrubbed in a tower, or the like, with a counter-current of water, which is fed in at such a rate that the whole or the greater part leaves the apparatus as vapour together with the gas.—L. A. C.

Nitric acid; Preparation of — from hot nitrous gases. Chem. Fabr. Griesheim-Elektron, Frankfurt. Ger. Pat. 304,322, 11.8.16.

Hot nitrous gases are passed through one or more towers supplied with dilute nitric acid from succeeding absorption towers so as to evaporate part of the water and increase the concentration of the acid to 67%.—A. B. S.

Hydrochloric acid and magnesia; Preparation of —. P. Beck, Nordhausen. Ger. Pat. 304,342, 7.8.17.

MAGNESIUM chloride or oxychloride is mixed with 2–5% of magnesium sulphate previously dissolved in water, the mixture formed into balls or briquettes and heated in the presence of water or steam. The production of magnesia dust is thereby prevented, and the yield of hydrochloric acid is greater than when more magnesium sulphate is present.

—A. B. S.

Sodium sulphate; Process of making —. Salzwirk Heilbrunn, A.-G., Heilbronn, Germany. Eng. Pat. 134,214, 20.10.19. (Appl. 25,676/19.) Int. Conv., 24.1.18.

A MIXTURE of sodium bisulphate and sodium chloride is heated to a temperature sufficiently high to yield molten sodium sulphate. Impurities are removed by passage of air or steam through the molten mass and/or the addition of an alkali, such as lime, baryta, or sodium carbonate. A finely divided product may be obtained by cooling with agitation, and crystalline sodium sulphate may be prepared by addition of the requisite amount of water. The hydrochloric acid evolved is freed from traces of hydrogen sulphide and sulphurous and sulphuric acids by passage over sodium chloride at a temperature slightly higher than that of the charge; the preheated salt is then employed for recharging the furnace.—L. A. C.

Phosphorus and phosphoric acid; Manufacture of —. W. H. Waggaman, Washington, D.C. U.S. Pat. 1,334,474, 23.3.20. Appl., 1.8.19.

BRIQUETTES prepared by compressing a finely ground mixture of natural phosphates, silica, a solid fuel, and a binder, are heated in a furnace to drive off phosphorus and phosphoric acid; flames and hot gases are then directed on to the surface of the molten mass, whereby further quantities of phosphorus and phosphoric acid are obtained.

—L. A. C.

Thorium; Process of separating — from other metals of the rare earths. O. Dietsche, Berlin-Lichtenberg, Germany, Assignor to The Chemical Foundation, Inc. U.S. Pat. 1,335,157, 30.3.20. Appl., 15.4.15.

THORIUM is separated from the other metals of the rare earths by treating a solution of these metals with a soluble fluorine compound corresponding to the amount of thorium present.—A. B. S.

Ammonium nitrate; Manufacture of —. Berlin-Anhaltische Maschinenbau-A.-G., Berlin. Ger. Pat. 299,602, 18.9.15.

NITRIC acid is diluted with a cold saturated solu-

tion of ammonium nitrate, and during the neutralisation of the acid with ammonia gas the solution is cooled by constantly circulating a portion through a cooler.—L. A. C.

Ammonium sulphate; Partial replacement of sulphuric acid by a bisulphate solution in the manufacture of —. Berlin-Anhaltische Maschinenbau-A.-G., Berlin. Ger. Pat. 299,742, 16.7.15.

A SOLUTION for the partial replacement of sulphuric acid in the manufacture of ammonium sulphate is prepared by dissolving a bisulphate in the liquor condensed from the gas both before and during the hot separation of tar.—L. A. C.

Ammonium sulphate; Manufacture of — from gas liquor and gypsum. Chem. Ind.-A.-G., and F. Wolf, Bochum. Ger. Pat. 299,752, 20.5.16.

A MIXTURE of gas liquor and gypsum is treated with carbon dioxide under pressure, and the solution of ammonium sulphate obtained is filtered and freed from hydrogen sulphide by heating and passage over hog iron ore.—L. A. C.

Ammonium sulphate; Manufacture of — from calcium sulphate and ammonium carbonate. Badische Anilin- und Soda-Fabrik, Ludwigshafen. Ger. Pat. 300,724, 30.7.16.

THE crude gypsum is calcined before treatment with ammonium carbonate to facilitate filtration of the ammonium sulphate solution from the lime sludge.—L. A. C.

Magnesia; Production of — for artificial stones and ceramic purposes. K. Schmid, Altmügeln. Ger. Pat. 303,870, 7.7.15.

MAGNESIA for use in the manufacture of artificial stone and for ceramic purposes is prepared by heating ammonium magnesium carbonate, obtained by adding ammonium carbonate to the waste liquor of the potash industry. The recovery of the ammonium salt from the mother liquor makes the process remunerative.—A. B. S.

Hydrogen sulphide; Preparation of — from sulphates. Apparate-Vertriebs Ges.m.b.H., Berlin-Wilmersdorf. Ger. Pat. 304,231, 14.7.16.

SULPHATES are reduced by means of hydrocarbons, e.g., natural gas or the like, at 840°–1050° C., and hydrogen sulphide is liberated from the sulphides formed by means of gases containing carbon dioxide.—A. B. S.

Hydrogen sulphide; Preparation of — from calcium sulphate. P. Beck, Nordhausen. Ger. Pat. 305,103, 9.8.17.

CALCIUM sulphate is converted into calcium sulphhydrate by treating it with barium hydrosulphide, the resulting barium sulphate being reduced to sulphide and the latter converted into the hydrosulphide.—A. B. S.

Potassium chloride; Extraction of — from carnallite by the cold process. Kaliwerke Grossherzog von Sachsen A.-G., Dietlas, and K. Hepke, Dorndorf. Ger. Pat. 316,215, 17.11.18.

As an improvement in the cold process of extracting potassium chloride from carnallite whereby the quantity of mother liquor employed is much reduced, a portion of the potassium chloride emulsion is withdrawn from the extraction apparatus, at a point situated between the inlet for the carnallite and the inlet for the extraction liquor, where the maximum concentration of magnesium chloride is not attained and where the liquor is sufficiently mobile to allow of the separation of the kieserite by gravity.—L. A. C.

Iron; Recovery of — from liquors containing ferric salts. H. Frischer, Zehlendorf. Ger. Pat. 317,633, 26.3.18.

IRON is removed from liquors containing ferric salts in solution by reducing the iron to the ferrous state and afterwards re-oxidising it to a basic ferric salt. Thus, an alum liquor may be treated first with barium sulphide (which forms ferrous sulphate) and then with barium peroxide, which forms basic ferric sulphate, $\text{Fe}_2(\text{OH})_2\text{SO}_4$. The reduction may also be effected by scrap iron or aluminium and the oxidation with sodium peroxide.—A. B. S.

Copper sulphate and hydrogen; Preparation of — by electrolysis. S. Simonek, Budapest, and P. Mike, Gödöllő, Hungary. Ger. Pat. 317,691, 2.12.16.

COPPER sulphate and hydrogen are produced by passing an electric current through dilute sulphuric acid in a cell divided into two parts by a diaphragm, using a copper anode.—A. B. S.

Sulphur retort. W. E. Clifford, Salt Lake City, Utah, and T. H. Green, Springfield, Ill., Assignors to United Filters Corp., New York. U.S. Pat. 1,332,512, 2.3.20. Appl., 25.1.19.

THE retort is formed in two sections, one being movable relatively to the other. A driving shaft is journaled in the fixed section and a rotary cage for the sulphur-bearing material is carried by the movable section. The cage telescopes within the fixed section of the retort as the movable section is moved toward and away from it. Co-operating clutches on the driving shaft and cage respectively are automatically brought into and out of operation as the cage is telescoped in and out of the fixed retort section.—J. F. B.

Sulphur; Production of — from calcium sulphate. Badische Anilin- u. Soda-Fabrik, Ludwigshafen. Ger. Pat. 302,433, 21.9.16.

A MIXTURE of calcium sulphate and fuel, with or without silicious or argillaceous matter to form a thin slag, is heated in a shaft furnace with a limited amount of air, so as to liberate the sulphur, which is removed from the furnace gases by washing with water. The slag may be used as a hydraulic cement.—A. B. S.

Sulphur; Purification of —. J. J. Hood, London. Eng. Pat. 140,844, 27.11.18. (Appl. 19,585/18.)

SEE U.S. Pats. 1,331,645-6 of 1920; J., 1920, 295 A. Spent oxide may be leached with a solvent of sulphur and the solution purified by the process described.

VIII.—GLASS; CERAMICS.

Sillimanite refractories; The Malinile process for the production of —. A. Malinovsky. J. Amer. Ceram. Soc., 1920, 3, 40-68.

THE complete conversion of clay into crystalline sillimanite cannot be effected in a firebrick kiln, but is readily accomplished in a blast or cupola furnace in the presence of coke. The excess of silica in the clay is volatilised, probably after being reduced first to silicon carbide and then to silicon, which ignites spontaneously with great evolution of heat. Iron, if present, acts as a catalyst, effecting the more complete reduction of the silica and forming some ferro-silicon, which sinks to the bottom of the furnace. Titanium is desirable, as it restrains the combination of iron with alumina and allows it to act wholly on the silica. A little iron is carried out by the blast as magnetite, but most of the iron remains in the metallic state. If cryolite is present the volatilisation of the silica is very rapid, and the alumina combines with some of the silica. Lime retards the formation of sillimanite. Felspar and mica facilitate the conversion into sillimanite above 1300° C. by dissolving the clay, sillimanite crystallising out of the fused solution. After heating for about three hours the contents of the cupola begin to boil, and the silica volatilises in dense bluish and finally brown fumes for about 2 hours, after which the process is completed, but the air blast is continued so as to produce a porous mass of sp. gr. 2.62-2.86, which is allowed to cool, then crushed, and the iron removed magnetically. The product is crude sillimanite melting at cone 36-40 (1790°-1920° C.); pure sillimanite melts at 1815° C. The product is highly refractory, not sensitive to sudden changes in temperature, and is not affected by acids, even hydrofluoric acid. It consists chiefly of intertwined crystals of sillimanite, but may contain a little amorphous sillimanite, glass (apparently also sillimanite), and slag. The crystals vary in length from 0.01 to 0.50 mm.—A. B. S.

Refractories; Physical characteristics of specialised —. (A) M. L. Hartmann and O. A. Hougen. (B) M. L. Hartmann and J. F. Kohler. Trans. Amer. Electrochem. Soc., 1920, 349-354, 355-358. [Advance copies.]

(A) *Spalling losses.*—Five to ten bricks of the same kind were dried, weighed, and used as "headers" in the front wall of an oil-fired furnace, where they were heated to 1350° C. for one hour. They were then removed and the heated end exposed for 15 mins. to a blast of cold air from a nozzle 2 in. diameter, delivering 27 cu. ft. per min. The operation was repeated ten times, and the percentage loss of weight was regarded as the spalling loss. The least spalling (0-12%) occurred with carborundum bricks and grade A fireclay; 43-65% with bauxite, zirconia, and grades B and C fireclays, whilst

chrome, silica, and magnesia bricks were completely destroyed with less than ten treatments. All the bricks cracked during the test. (b) Abrasion tests were made by cutting a groove in the ends of each brick so as to expose the maximum area to cutting and then applying the bricks at a constant pressure of 25 lb. for 5 mins. to a carborundum grinding wheel. The bricks were tested when cold and also immediately after heating to 1350° C. The variations in bricks of the same kind and even from the same manufacturer were large. The relative resistance to abrasion of the cold bricks is shown by the following figures, which represent the difference in the depth of the groove before and after the test: carborundum, zirconia, and bauxite, 0.01–0.2 in.; grade C fireclay, magnesia, and chrome bricks, 0.05–0.07 in.; silica bricks, 0.17 in.; grades A and B fireclay, 0.25–0.26 in. The corresponding figures for bricks at 1350° C. are: carborundum and bauxite, 0.1–0.4 in.; zirconia, recrystallised carborundum, and grade C fireclay, 0.06–0.07 in.; grades A and B fireclay, 0.09–0.11 in.; chrome, 0.27 in.; magnesia, 1.25 in.; the silica brick spalled too badly to permit any abrasion test. —A. B. S.

Pottery; The use of American raw materials in the manufacture of white ware —. A. V. Bleininger and W. W. McDanel. J. Amer. Ceram. Soc., 1920, 3, 134–148.

SATISFACTORY white pottery can be made from raw materials of American origin.

Silicious sagger mixtures. M. R. Hornung. J. Amer. Ceram. Soc., 1920, 3, 69–76.

IN making saggars, chert, especially if it has been calcined, is more satisfactory than quartzite. To produce a sagger which neither shrinks nor expands about 60–65% of raw chert or quartzite or their equivalent must be present. Finely ground silicious materials are preferable to coarser ones. The addition of calcined flint-clay reduces the tendency to spall. A mixture of raw clay 50, calcined flint clay 20, and chert 30% is recommended. —A. B. S.

Terra-cotta glazes; Development of —. E. C. Hill. J. Amer. Ceram. Soc., 1920, 3, 13–25.

THE effect of adding tin oxide or barium or magnesium carbonate to a Bristol or terra-cotta glaze containing felspar, flint, clay, whiting, and zinc oxide was investigated. Tin oxide increases the whiteness of a glaze, but if more than 7% is added it tends to produce crawling and cracks. The fusibility of the glaze is reduced in proportion to the tin oxide or barium carbonate added. Magnesium carbonate if present in the proportion of more than 0.20 equivalent of MgO tends to cause crawling and cracks. Addition of magnesia makes the glaze more refractory. A decrease in the proportion of clay present usually increases the fusibility of the glaze, but decreases the gloss in glazes high in clay. Addition of clay increases the fusibility only when there is at least 0.40 equivalent of CaO present. —A. B. S.

Tin oxide in glazes; Substitutes for —. R. H. Minton. J. Amer. Ceram. Soc., 1920, 3, 6–12.

IN leadless terra-cotta and porcelain glazes the presence of zinc oxide is useful. Tin oxide and its substitutes and barium oxide increase opacity more than clay. In a terra-cotta glaze the presence of both barium and zinc oxides improves opacity. Leukonin (sodium metantimonate) and antimony oxide, where they can be used, are almost as efficient as tin oxide in producing opacity, but zirconium oxide (terrar) appears to be the best substitute for tin oxide when it can be obtained at a sufficiently low price. Alumina produces matt glazes. —A. B. S.

PATENTS.

Double-walled glass vessel on the Dewar system and process for manufacturing the same. Isola Ges. für Wärme und Kälte-Isolierung m.b.H., Berlin. Eng. Pat. 137,541, 9.1.20. (Appl. 744/20.) Int. Conv., 13.10.15.

DEWAR vessels with walls 2–5 mm. thick and up to 5–10 litres capacity may be made if the vessels, as soon as they are formed, are placed in a casing of metal, asbestos, or other substance, previously heated to a high temperature (400°–500° C.), and the casing and its contents placed in a hot oven, heated to 700°–800° C., and then cooled very slowly. —A. B. S.

Glass; Method of and apparatus for drawing —. A. E. Spinasse, Mount Vernon, Ohio. U.S. Pat. 1,336,056, 6.4.20. Appl., 16.10.15.

THE glass article is drawn from a portion of the glass segregated by a device having sloping polished walls and means for circulating water through it so as to cool it sufficiently to avoid adhesion of the glass. —A. B. S.

Ceramic article [; Refractory —] and method of making same. W. M. W. Horn, Teplitz, Austria, Assignor to The Chemical Foundation Inc. U.S. Pat. 1,335,167, 30.3.20. Appl., 28.10.14.

A REFRACTORY ceramic material, suitable for the heating elements of radiators and capable of withstanding changes in temperature between 20° and 120° C., consists of plastic fireclay, ground grog, and lean kaolin, and is substantially free from quartz, felspar, alkalis, and alkaline earths. —A. B. S.

Tunnel oven; Water-smoking in a —. F. K. Meiser, Nuremberg. Ger. Pat. 315,774, 18.2.19.

THE hot flue gases from the preheating zone are withdrawn from the interior of the tunnel and caused to heat a series of pipes through which is passed a supply of air, the latter being applied under pressure to water-smoke the goods. —A. B. S.

Kilns; Operation of continuous down-draught chamber —. F. K. Meiser, Nuremberg. Ger. Pat. 316,535, 27.6.17.

HER air for combustion is led independently and simultaneously by means of supplementary flues into two chambers being fired. If required, in one chamber the supply of air may be restricted to ensure reducing conditions, whilst in the other oxidising conditions may prevail. By the proposed arrangement double the customary quantity of air is passed through the cooling chambers and a correspondingly larger amount of waste heat is recovered. —A. B. S.

Artificial grinding stones; Production of — for wet grinding. M. Mudrack, Wolfenbüttel. Ger. Pat. 317,583, 3.5.18.

WATERPROOF artificial grindstones are made of a mixture of magnesium chloride lye, "hydraulic magnesia," and quartz, carborundum, emery, or emery-substitute, with oil, wax, or grease. —A. B. S.

Enamelling and annealing furnace. P. Dupont, Paris. U.S. Pat. 1,335,279, 30.3.20. Appl., 14.3.18. SEE Eng. Pat. 114,618 of 1918; J., 1918, 700 A.

Pottery and other like articles; Casting of —. B. J. Allen, Blythe Bridge, and R. Y. Ames, Gidea Park. U.S. Pat. 1,336,180, 6.4.20. Appl., 14.8.17.

SEE Eng. Pat. 110,649 of 1916; J., 1917, 1274.

Ceramic support for contact substances. Ger. Pat. 317,979. See I.

Protecting apparatus. Ger. Pat. 318,033. See I.

Magnesia. Ger. Pat. 303,870. See VII.

IX.—BUILDING MATERIALS.

Portland cement; Thermal phenomena in the setting of —. F. Killig. Zement, 1919, 8, 499—501, 511—515, 523—527, 536—538, 548—551. Chem. Zentr., 1920, 91, 11., 280—281.

The amount of heat evolved during the setting of cement was determined by means of a calorimeter, and tests with a number of samples indicate that measurement of the heat evolved may be more satisfactory than the use of Vicat's needle for investigating the setting of cement.—A. B. S.

PATENTS.

Potassium compounds; Process for recovering — in connection with cement manufacture. A. Mond, London. From The International Precipitation Co., Los Angeles, Cal., U.S.A. Eng. Pat. 134,920, 13.11.18. (Appl. 18,554/18.)

Sodium or magnesium chloride or other alkaline-earth chloride is added to a cement raw mix, or to the fuel, or to both, and the cement mix is heated to a temperature sufficient to drive off any potassium chloride present without melting the mixture. The condensed vapour or dust is collected (e.g., by electrical precipitation) and leached with water and the potassium chloride recovered by evaporation and crystallisation. Any insoluble potassium compounds in the residue after leaching are recovered by adding this residue to another portion of cement raw mix and proceeding as before. The mother liquor is used instead of part of the water in a wet grinding cement plant or it is employed to wet the fuel in a dry grinding plant so as to use any surplus sodium chloride present, or part of the mother liquor may be used for this purpose and the remainder as a solvent of potassium salts in fresh quantities of dust.—A. B. S.

Alkali-bearing rocks; Treatment of — [for production of cement with volatilisation of the alkali]. F. Krupp A.-G. Grusonwerk, Magdeburg-Buckau. Ger. Pat. 315,464, 7.7.18. Addition to 304,080 and 308,690 (J., 1918, 374 A; 1919, 179 A).

By the addition of sulphur, iron sulphide, etc. to the calcium salt (calcium sulphate) mentioned in the chief patent, and by the action of the oxygen in the air and the furnace gases, the acid is liberated and caused to combine, in presence of steam, with the alkali, the potassium sulphate formed being condensed in suitable chambers.—W. J. W.

Concrete; Reinforced — for marine purposes. L. R. Ferguson, Philadelphia, Pa., U.S.A. Eng. Pat. 140,126, 3.10.18. (Appl. 16,100/18.)

In reinforced concrete partly submerged in seawater, the metallic reinforcement in the portion above the water-level or exposed to the atmosphere is made of electro-plated, galvanised, or other rust-resisting or non-corrodible metal to prevent cracking and spalling of the concrete.—A. B. S.

Asbestos-bearing rock; Process of treating —. Asbestos cement. H. S. Ashenhurst, Assignor to J. D. Hubbard, Chicago, Ill. U.S. Pat. 1,317,852 and 1,317,853, 7.10.19. Appl., 18.11.18.

An asbestos cement having a volume-weight of about 25 lb. per cub. ft. is prepared by grinding waste "asbestos sand" in a ball mill,

separating the asbestos by treatment on a screen with 900 meshes per sq. in., and then allowing it to fall freely through a long pipe. When the product is used as a cement, the alkali silicates present pass into solution and are decomposed by atmospheric carbon dioxide with liberation of silicic acid, which acts as a binder.

[Heat-] insulating material made of basic magnesium carbonate and fibres; Production of —. Lipsia Chem. Fabr., Mügeln. Ger. Pat. 303,310, 16.3.15.

Basic magnesium carbonate is precipitated on mineral, vegetable, or animal fibres, and is either drained in a press or allowed to set therein. The process may be carried out in two stages, normal magnesium carbonate being precipitated from a saline liquor and then converted into the basic carbonate by boiling with water.—A. B. S.

Xylolite; Production of non-expanding —. E. Kühn, Bahnhof Gleschendorf. Ger. Pat. 317,493, 22.5.19.

The addition of 1—2% of wood ashes to the materials customarily used for xylolite prevents it cracking as a result of expansion.—A. B. S.

Lime-sand bricks; Hardening —. G. Beil, Königsberg. Ger. Pat. 317,845, 15.6.18.

By placing the freshly-made bricks in a suitable tunnel and heating them by means of exhaust steam before passing them into the ordinary hardening chamber, the time required for hardening is reduced by three hours.—A. B. S.

Slag; Utilisation of — as a building and other constructional material. T. F. Hoare, Bradford. Eng. Pat. 140,874, 12.2.19. (Appl. 3470/19.)

Sulphur from calcium sulphate. Ger. Pat. 302,433. See VII.

Magnesia. Ger. Pat. 303,870. See VII.

Moulded articles. Eng. Pat. 124,669. See XI.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Carbon in iron [: Determination of —]. T. D. Yonsen. Trans. Amer. Electrochem. Soc., 1920, 43—58. [Advance copy.]

In estimating carbon in irons containing less than 0.10% errors occur chiefly in absorption and weighing. To eliminate these errors a method is described in which the carbon dioxide is separated by freezing with liquid air, and is then allowed to expand into a known volume and the increase in pressure noted. The analysis is carried out in three stages, namely, with the sample (a) evacuated cold, (b) heated to 600° C. in vacuo, and (c) heated to 1000° C. in oxygen. This differentiates between the carbon due to gas admitted into the tube when introducing the sample, that existing as adsorbed carbon monoxide or dioxide, and that existing in combined form. In the case of electrolytic iron the amounts of carbon found for the three stages were 0.005%, 0.005%, and 0.005% respectively. By taking suitable precautions in sampling, weighing, etc. the accuracy of the determination is within $\pm 0.0001\%$.—J. W. D.

Carbon determination in ferro-alloys. C. J. Rottmann. Trans. Amer. Electrochem. Soc., 1920, 59—68. [Advance copy.]

By the method described an accuracy of 0.002% can be consistently attained in estimating carbon

in ferro-alloys such as vanadium-, chrome-tungsten-, and chrome-nickel steels. The sample is cleaned with ether in a Soxhlet apparatus, then heated *in vacuo* for several hours at 450° C., and finally heated in oxygen at 1000° C., the carbon dioxide being absorbed in a new type of potash bulb which is compact, light, easily manipulated, and gives complete absorption. Combustion is carried out in a thick-walled silica tube heated either by a nichrome resistance wire or by a carbon resistance furnace. If the latter furnace is used the tube has to be well protected with alundum to prevent penetration of external carbon. No advantage is gained by heating to 1450° C.—J. W. D.

Corrosion of wrought iron; Influence of enclosed slag on the —. L. T. Richardson. Trans. Amer. Electrochem. Soc., 1920, 99—104. [Advance copy.]

PIECES of Swedish iron and wrought iron taken on transverse and longitudinal sections were exposed to the weather for varying periods. The loss in weight and depth of the corrosion pits were found to be approximately the same in both transverse and longitudinal sections. Microscopical examination of the sections in no case gave visible evidences of slag inclusions hindering the corrosion, as several of the slag layers were penetrated, and it is concluded that any superior resistance to corrosion that wrought iron may have is not due to slag inclusions, but to some other cause such as purity of the iron.—J. W. D.

Mild steel; Slag inclusions and decoxidation processes in —. P. Oberhoffer and K. d'Huirt. Stahl u. Eisen, 1919, 39, 165—169, 196—202.

By the oxidation of iron at high temperatures two non-metallic products make their appearance in the microstructure, *viz.*, FeO and Fe₂O₃, the proportion of FeO to Fe₂O₃ increasing as the temperature is raised. The oxides occur sometimes as isolated particles, sometimes as cell walls around the crystal of iron. These oxides decarburise steel. In the molten condition iron oxide compounds exert a solvent action on iron, which may be retained in solid solution on cooling. Ferrous and ferric oxides form solid solutions with each other. Up to 400° C. treatment with hydrogen for 20 min. produces no change, but at 500° C. in 40 min. the bright constituent of the eutectic formed by melting mill-scale is reduced to metallic iron. It is not till 950° C. is reached that the darkest constituent is reduced, 30 min. being required. The exact nature of the two constituents cannot be determined. By forging at 900° C. oxide inclusions in electrolytic iron were appreciably deformed. The mean size of these inclusions was about 25μ, the lower part of the melt containing a larger number than the upper parts. A eutectic structure of Fe-FeO, very similar in character to that of the Cu-Cu₂O eutectic, was observed, which eutectic is very rich in iron. Manganese oxide occurs in greyish particles which, unlike ferrous oxide, are well crystallised, the melting point being higher than that of iron. These inclusions are found towards the top of the ingot. There appears to be some tendency to form a MnO-Fe eutectic. Deoxidation occurs more readily with manganese alloys containing carbon than with pure manganese, and, in addition, the higher manganese alloys reacted with oxygen more readily than those containing less manganese. The ratio of the manganese oxide to ferrous oxide is given as 2.7:1 in oxidised melts rich in manganese. The reaction $\text{FeO} + \text{Mn} = \text{MnO} + \text{Fe}$ does not represent the conditions, no pure MnO being formed. The oxide inclusions appear to consist of more than one constituent, and are in part reducible by hydrogen at 950° C.—F. C. Th.

Carbon steel; Mechanism of quenching in —. P. Chevenard. Rev. Mét., 1919, 16, 17—79. (Cf. J., 1918, 91 A, 420 A.)

IN the case of the more reversible steels where the transformation on cooling occurs entirely at a high temperature, 600°—700° C. (Ar₁), the material is brought into the normal condition and consists of pearlite or troostite, while where the $\gamma \rightarrow \alpha$ change occurs between 150° C. and 300° C. the structure is martensitic. Between these two extremes a complete gradation of intermediate stages may be realised, both Ar₁ and Ar₂ being present and the structure comprising both troostite and martensite. By studying the volume changes of wires very delicate indications of the internal changes occurring can be obtained. To obtain in a steel the same intensity of hardening the cooling must be more and more rapid as the maximum temperature is brought nearer to the Ac point. Further, as the carbon content is lowered the rapidity of quenching must be increased to obtain the same effect. Martensite appears to be an unstable solid solution of carbon in α -iron. A full description of the apparatus designed for registering the dilation of steel wires with temperature is given.—F. C. Th.

Galvanised steel; Metallographic study of —. Y. Tajiri. Soc. Naval Architects, Japan. Engineering, 1920, 109, 327—329.

IN the case of mild steel galvanised by immersion in molten zinc at 650° C., the layer in contact with the steel surface is very hard and brittle. The crystals are perpendicular to the steel surface, and appear to consist of an iron-zinc alloy with 5% Fe. The cleavages are weakest in a direction perpendicular to the steel surface, and under shock this layer tends to split in this direction. Between this layer and the outer layer of zinc is generally found a granular structure of lower iron content (about 2%), which is less hard and brittle and less easily broken. A hexagonal structure may be developed. A decarburising action of the zinc is noted on the surface of the metal after long immersion. It is considered better practice to galvanise the steel before wire drawing rather than afterwards on account of the loss of strength in the latter case due to the heating. As regards the influence of galvanising, the ultimate strength of a mild steel bar was reduced from 25.2 to 24.0 tons, and the yield point from 22.0 to 19.0 tons per sq. m., whilst the elongation (% on 10 diams.) increased from 24.7 to 25.

—F. C. Th.

Copper; Effect of cold drawing on physical properties of commercially pure —. W. E. Alkins. Inst. of Metals, 12.3.20. [Advance copy.] 62 pages.

THE abnormality previously observed in the change of tensile strength with progressive reduction of area (this J., 1918, 587 A) is shown to occur at a reduction which varies with the previous annealing treatment and with the severity of the successive reductions of area. The curves expressing the relationship of the percentage reduction of area with tensile strength, scleroscope hardness, specific volume, and elongation in the tensile test all show two distinct portions connected by an approximately horizontal step over a small range. The breaks all occur at approximately the same reduction. A periodicity in the drawing operation is suggested by the differential tarnishing of the wires. If tarnished wires are lightly re-polished a banded appearance is found which bears some relationship to the diameter of the wire. In the preparation of wires of high electrical conductivity better results are obtained from a large number of light draughts than from fewer heavier ones.—F. C. Th.

Copper; Influence of cold rolling on physical properties of —. F. Johnson. Inst. of Metals, 12.3.20. [Advance copy.] 31 pages.

When copper containing 99.91% Cu and 0.05% O was rolled abnormalities in the effect of rolling upon the physical properties were detected at the following reductions in thickness: 17, 31, 50, 67, 88, suggesting a periodic effect. The ordinary mechanical properties in tension and the lateral spread of the metal during rolling agreed well. The minimum elongation was recorded with a reduction of thickness of about 90%, after which it increased with further rolling from 11.2% to 13.65% after a reduction of 97.8%. The true elastic limit after a reduction of 50% was 8.1 tons per sq. in., and after 58%, 15.8 tons.—F. C. Th.

Copper; Effects of hydrogen on —. W. C. Hotherhall and E. L. Rhead. Inst. of Metals, 12.3.20. [Advance copy.] 10 pages.

SOUND castings can be obtained from copper in which about 0.02% of hydrogen is present if the metal is cast at a suitable temperature. Unless, however, a considerable amount of arsenic is present a badly piped ingot will be produced. Sulphide distributed more or less evenly throughout the metal in the untreated state is concentrated at the crystal boundaries in hydrogenised copper. This lowers the electrical conductivity and renders the copper liable to fail prematurely under load. The hydrogen present is believed to exist in solid solution.—F. C. Th.

Copper; Idiomorphic crystals of electro-deposited —. W. E. Hughes. Inst. of Metals, 12.3.20. [Advance copy.] 14 pages.

WELL-FORMED crystals were obtained under the following conditions:—The bath consisted of 1½ kilos. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, 200 c.c. perchloric acid (sp. gr. 1.12), and 4½ litres of water. The cathode was an iron cylinder lightly coated with copper. The current density decreased during the work from 14 to 12.5 amps. per sq. ft., the voltage being 0.4. At room temperature 3 or 4 days were required for well-formed crystals. These are believed to be tetrakis-hexahedra, and are certainly not octahedra.—F. C. Th.

Brass; Removal of internal stress in 70:30 — by low-temperature annealing. H. Moore and S. Beckinsale. Inst. of Metals, 12.3.20. [Advance copy.] 11 pages.

THE minimum time in which the internal stresses in cold-worked 70:30 brass were completely removed by low-temperature annealing were:—At 200° C., 96 hrs.; 225°, 48; 250°, 5; 275°, 1 hr.; 300°, 20 min.; 325°, 5 min. The minimum times in which notable softening was produced were found to depend on the original hardness. The harder the brass, the lower the temperature and the shorter the time of annealing required to cause a reduction of hardness. For a Brinell hardness not exceeding 165 (2 mm. ball, load 40 kilos.) the internal stress can be completely removed without appreciable loss of hardness by annealing for 1 hr. at 275° C. or for shorter times at slightly higher temperatures or at 250° C. for 5 hrs. At 100° C. the internal stress is not appreciably reduced even after many weeks.—F. C. Th.

[*Corrosion of 70:30 brass condenser tubes.*] Fifth Report of the Corrosion Committee of the Inst. of Metals. G. D. Bengough, R. M. Jones, and R. Pirret. Inst. of Metals, 12.3.20. [Advance copy.] 71 pages.

IN condenser tubes of 70:30 brass the surface layer consists of structureless and highly distorted metal, the resistance of which to corrosion by saline and fresh waters is undoubtedly much greater than

that of the underlying crystalline metal. Whenever this surface layer is penetrated corrosion of the tube will proceed at an increased rate. The thickness of the layer is usually of the order of 0.01 mm. The types of corrosion of brass condenser tubes may be divided into five classes. *General thinning* is usually too slow to be of any serious consequence in practice, but in fresh water, especially in the presence of free acid, rapid general thinning may occur. In 6 weeks water containing 3 pts. HCl per 100,000 caused a loss of thickness of 2–4%. *Deposit attack* is the principal cause of pitting. In sodium chloride solution the cuprous oxide formed on the surface gradually changes to cuprous chloride. When this adheres it is gradually changed to cupric chloride and cuprous oxide; the corrosive action of the former is very rapid, the action being both recurrent and local. Foreign bodies, especially colloids, lying in the tube, act as loci for such pitting. It is necessary, therefore, to keep the tubes clean. *Layer dezincification* is characterised by a disintegration of the tube with the re-deposition of copper over large areas, and occurs under both marine and fresh water conditions. In the latter case it is often associated with acid water. *Local dezincification* is a type of deposit attack stimulated by the presence of foreign bodies. It occurs only in sea-water, and is always associated with adhering white salt (colloidal zinc oxychloride with some carbonate). It occurs spontaneously at 40°–50° C. in a few days. Great and unexplained differences are found in the behaviour of different batches of tubes to this action. *Water-line attack*.—The increased corrosion of a brass tube partly immersed in sea-water occurs not at the water line, but up to as much as 2 cm. above it. The attack is not uniform, but is concentrated at areas covered by salt. Electrolytic protection of brass tubes slows down but does not necessarily inhibit corrosion, currents as large as 20–25 amps. per 1000 sq. ft. being insufficient.—F. C. Th.

Copper-aluminium-zinc alloys rich in zinc. E. H. Schulz and M. Wachler. Metall u. Erz, 1919, 16, 170–176, 195–201.

THE solubility of aluminium in zinc is 0.75% at 380° C. and at room temperature. The addition of 2% of copper produces no change in the diagram for the zinc-rich zinc-aluminium alloys, but beyond this content a ternary eutectic appears containing 6.5 Al and 2% Cu, and melting at 370° C. The addition of 7% of copper prevents the formation of blow holes. By the addition of aluminium to zinc containing copper a rapid increase of hardness occurs up to 3% Al, after which no change occurs up to 10%. Addition of copper, especially up to 3%, to zinc-aluminium alloys, produces a marked hardening. An alloy with 3.5% Al and 4% Cu has the same hardness as one containing 9% Cu and free from aluminium. A given hardness is attained with the minimum additions if both copper and aluminium are used. The tensile strength curves of the ternary alloys bear little or no relationship to those of hardness. Both copper and aluminium raise the tenacity of zinc fairly proportionally to the content, the effect of copper being 3 or 4 times as great as that of aluminium. A maximum stress of 15 kilos. per sq. mm. may be obtained by the addition of 4.7% Cu, or 4% Cu and 3% Al, or 2% Cu and 9% Al. Pure zinc possesses no elastic limit, plastic deformation occurring under all loads. By addition of copper elastic limits up to 22 kilos. per sq. mm. at 7% Cu and 30 kilos. per sq. mm. at 10% Cu are obtained. The effect of aluminium is very similar. In the ternary alloys the elastic limit is related to the hardness. An elastic limit (in compression) of 30 kilos. per sq. mm. is obtained with the ternary alloys containing 11% Cu and 11% Al, 4% Cu and 1% Al, 2% Cu and 2% Al, or 1% Cu and 5% Al.—F. C. Th.

Zinc alloys with aluminium and copper. W. Rosenhain, J. L. Haughton, and K. E. Bingham. *Inst. Metals*, 12.3.20. [Advance copy.] 57 pages.

THE constitution of zinc alloys containing up to 10% Cu and 15% Al is illustrated by diagrams showing the primary, secondary, tertiary, and quaternary separation. Addition of 1% of copper to zinc makes possible a reduction of 90% in thickness by cold rolling without signs of cracks; a further 2% of aluminium causes cracks to appear at a much earlier stage. For hot rolling the alloys a temperature just below the transformation temperature $\eta + \gamma = \beta$ (285° C.) gives better results than one above it. Tensile tests on chilled castings cast at as low a temperature as possible showed that with a constant copper content, the addition of aluminium raised the tensile strength to a marked extent. With more than 4% Al the addition of copper gave a maximum tensile strength at 3%. In hot-rolled alloys the addition of both copper and aluminium raised the tensile strength. Heat treatment had practically no effect on the mechanical properties of chilled bars, but a considerable one on the hot-rolled alloys. Annealing an alloy with 3% Cu and 7% Al at 300° C. raised the tensile strength and considerably reduced the elongation. This anomalous behaviour is attributed to the formation of a large amount of amorphous material during the later stages of rolling, which tends to recrystallise readily. The ageing properties of the alloys render them useless for most purposes. When tested one year after rolling most of the alloys had fallen off considerably in ductility and slightly in tensile strength. Alloys containing Zn 88, Cu 4, and Al 8%, recommended by Guillet and Bernard (this J., 1918, 769 A), undergo a certain amount of shrinkage with ageing, and in the rolled condition deteriorate so as to become useless after a few months. Where a small amount of shrinkage is not an objection alloys containing 3% Cu and 6–15% Al are useful where great strength is required. Special attention is drawn to the great improvement in the mechanical properties of zinc, both in the cold-rolled and hot-rolled conditions, by the addition of a small quantity of copper, e.g., Zn 99 Cu 1.—T. H. Bu.

Bronze plating. F. C. Mathers and S. Sowder. *Trans. Amer. Electrochem. Soc.*, 1920, 83–86. [Advance copy.]

BRONZE can be deposited from a bath containing 5% potassium hydroxide, 0.5% potassium cyanide, 0.38% ammonium stannic chloride, and 1.5% potassium copper cyanide at 40°–50° C., and a current density of 0.4 amp. per sq. dm. (3.75 amp. per sq. ft.), using bronze anodes, with good results. The anodes, however, do not corrode satisfactorily in an oxalate bath, and the authors therefore recommend the use of copper anodes and a bath consisting of copper and tin oxalates dissolved in ammonium oxalate, together with a little potassium sulphate, citric acid, and ammonium citrate or similar salts. The tin content of the bath is maintained by occasionally precipitating copper from a portion of it with metallic tin.—A. R. P.

Tin-phosphorus alloys. A. C. Vivian. *Inst. Metals*, 12.4.20. [Advance copy.] 35 pages.

A SERIES of alloys was prepared in sealed glass tubes embedded in sand in an enclosing steel case, a thermocouple being cemented into contact with the glass tube. Up to 8% P the alloys were obtained by carefully fusing a high-percentage product at atmospheric pressure. From 6.5% to 20% P conjugate solutions occur, but between 16% and 30% P there is little sign of conjugate solutions remaining in the cooled ingot. Above 30% elementary phosphorus appears, but conjugate solutions are roughly indicated at high temperatures. Up to about 12% P the ground mass contains 14.7% P, which

represents the maximum solid solution (α_1) of tin in Sn_3P_2 (α_2). The $\alpha\beta$ eutectic contains 20.5% P and freezes at 540° C. The β phosphide contains 25.8% P, corresponding to Sn_3P_4 . Above 26% P the γ phosphide (about 44% P) occurs as black strings. The $\beta\gamma$ eutectic contains about 31.3% P and freezes at 530° C. Above 44% P the alloys contain red phosphorus. The vapour phase is necessary for the formation of alloys above 2.5% P. The tin arrest decreases with the phosphorus content to nil at 14.5%. From the data obtained a temperature-concentration diagram up to 50% P is suggested.

—T. H. Bu.

Manganiferous silicate slags; Reduction of —. E. F. Kern. *Trans. Amer. Electrochem. Soc.*, 1920, 221–232. [Advance copy.]

SPECIALLY prepared manganiferous silicate slags were reduced experimentally in an electric furnace to produce manganese-silicon-iron alloys of varying composition. Anthracite was used as reducing agent, and the most suitable temperature for reduction was found to be 1470° C. The amount of available metal recovered from the slags varied from 19 to 90%, the loss being due to incomplete reduction and volatilisation. By treatment of a lead blast-furnace zinc slag in a similar manner 75% of the lead and 70% of the zinc were distilled off, and 91% of the iron, 95% of the manganese, and 62% of the copper recovered.—J. W. D.

Electrolytic chromium. G. J. Sargent. *Trans. Amer. Electrochem. Soc.*, 1920, 275–292. [Advance copy.]

A COON deposit of chromium may be obtained by electrolysis of a solution containing 24.5% CrO_3 and 0.3% $\text{Cr}_2(\text{SO}_4)_3$ at 20° C. with a current density at the cathode of 10 amps. per sq. dm. A yield of 0.1 grm. of chromium per ampère-hour is obtained with a voltage of 3 volts and an electrode distance of 2.5 cm. The light grey deposit has scleroscope hardness 75, is unaffected by air, oxygen, or chlorine below 300° C., and may be obtained up to 1.25 cm. thick. Lead anodes give the best results, as the chromic acid reduced at the cathode is re-oxidised at the anode and the composition of the bath thus kept constant. No deposit of chromium is obtained if there is no chromium sulphate present.—A. R. P.

Calcium; Electrolytic production of —. P. H. Brace. *Trans. Amer. Electrochem. Soc.*, 1920, 69–82. [Advance copy.]

THE electrolyte (pure calcium chloride) was first melted by alternating current in an Acheson graphite pot fixed on a water-cooled base and surrounded with insulating material. When the pot was full of molten electrolyte the alternating current was switched off and direct current used for the electrolysis. The anodes were made of graphite and a round-ended iron nut screwed on to a copper rod acted as cathode, which was rotated during the experiment and gradually withdrawn as the deposit grew. A current of 200 amps. was used and was kept uniform to within one amp. during the whole run. The electrolyte was prepared by heating calcium chloride with a small quantity of calcium and stirring with an iron rod until no more gas was evolved and then pouring into iron moulds. Satisfactory deposits in the form of rods about 14 in. long and $\frac{1}{8}$ in. diam. were obtained, which could be worked into wire and sheet by the usual methods. The metal contained 1.08% Cl; sp. gr., 1.46; elect. resist., 6.77 microhms per cm. cube at 22° C.—A. R. P.

Gold and silicon; Alloys of —. C. di Capua. *Atti R. Accad. Lincei*, 1920, 29, i., 111–114.

GOLD and silicon are miscible in all proportions in the liquid condition, but are completely immiscible

in the solid state. The melting point of gold is lowered by about 800° C. by 6–7% Si. (Cf. J.C.S., ii., 323.)—T. H. P.

Sodium amalgam; Influence of various metals on the decomposition of — by water. E. Muller and A. Riedel. Z. Elektrochem., 1920, 26, 101–109.

The rate of decomposition of sodium amalgam by water is very much accelerated by the presence of a small piece of chromium, ferromolybdenum, ferrovanadium, or ferrotungsten. The catalysis is due to an increase of surface caused by the solution and reprecipitation of the catalyst. It will be possible to apply this action to the mercury electrode process for the manufacture of sodium hydroxide if it is found possible to remove entirely the finely divided catalyst from the mercury at the end of the process; otherwise the whole current will not be used in forming sodium amalgam but a portion will be used in liberating hydrogen.—J. F. S.

Metals; Alteration of — by cold working and alloying. P. Ludwik. Z. Ver. deuts. Ing., 1919, 142–144. Chem.-Zeit., 1919, 43, Rep., 308.

A GENERAL account of the effect of cold work on a crystalline aggregate is given. The irreversible changes due to alloying are probably different in nature from the changes due to cold work.

—F. C. Th.

Thermal electromotive force; Study of — as an aid to the investigation of the constitution of alloy systems. J. L. Haughton. Inst. Metals, 12.4.20. [Advance copy.] 25 pages.

THE forms of the E.M.F.-temperature or E.M.F.-composition curves for various alloy systems are described (cf. Broniewski, Ann. Chim. Phys., 1912, 25, 5). The author has investigated theoretically the effect of the arrangement of the constituents in eutectiferous systems, and finds that if they are arranged in series alternately the number of sections does not affect the result. If the constituents are arranged in parallel the E.M.F. generated will be the same as with the series arrangement if the resistance of the constituents is the same; otherwise it will be less. These deductions were verified by experiments on copper and nickel. Practical details are given for the investigation of alloy systems by measurement of the thermal E.M.F., and possible errors due to the Seebeck, Peltier, Thomson, and Benedicks effects are considered.—T. H. Bu.

Blast-furnace gas; Production of power from —. S. H. Fowles. Inst. Elect. Eng., 11.3.20. Engineering, 1920, 109, 443–445.

It is estimated that 1,000,000 h.p. is being constantly wasted in Great Britain in the form of potential energy from blast-furnace gas. The use of blast-furnace gas for boiler-firing is uneconomical, as even with modern plant and clean gas only 30% efficiency is attained. In present practice 40% of the gas is used on the stoves, 15% on the blowers, and none on the boilers, so that 45% is available for other purposes, equivalent to 3000 k.w.-hours per furnace per hour. The furnace blowers require 800 h.p., taking 0.2 ton of coal and 15% of the gas, the total B.Th.U.s required being 20,824,000. The economy on 50 furnaces amounts to 400,000 tons of coal per annum, which is almost equal to the coal required to produce the total units sold in 1911–12 by the 303 electricity works in the United Kingdom. The Halberg-Beth plant for gas-cleaning is recommended, the potash being recovered and the moisture being removed from the gas, making it better for gas-engine use. The residual dust is given as 0.002 gm. per cub. m.

—A. G.

Ternary alloys; Model for representing constitution of —. W. Rosenham. Inst. of Metals, 12.3.20. [Advance copy.] 8 pages.

PATENTS.

Chromium-steel alloy. J. L. Cox, Assignor to Midvale Steel and Ordnance Co., Philadelphia, Pa. U.S. Pat. 1,333,651, 16.3.20. Appl., 1.5.19.

THE alloy contains over 1% but less than 1.5% of carbon and over 20% but less than 60% of chromium.—T. H. Bu.

Titaniferous iron ore; Process for treating —. J. J. W. H. van der Toorn, Assignor to Industrie & Mijnbouw Maatschappij "Titan," The Hague, Netherlands. U.S. Pat. 1,331,001, 16.3.20. Appl., 25.3.18.

A MIXTURE of finely-ground titaniferous iron ores, coal, and limestone flux is briquetted, and the briquettes are reduced to obtain metallic iron. (Cf. Eng. Pat. 114,309 of 1918; J., 1919, 108A.)

—T. H. Bu.

Steel; Treating —. E. F. Kenney, Philadelphia, Pa. U.S. Pat. 1,331,379, 23.3.20. Appl., 20.11.19.

STEEL shapes are finished in a rolling mill at a red heat, allowed to cool to between 500° and 1200° F. (260°–650° C.), and placed in a furnace maintained between these temperatures until the heat of the different parts is substantially equalised. They are then withdrawn and straightened.—A. R. P.

Sheet-iron or other metal; Process for coating — [with metals]. H. Lippmann, Berlin. Ger. Pat. 310,137, 23.3.18.

THE metal to be coated is treated with aluminium, or given a preliminary coat of aluminium paint (Ger. Pat. 312,480; J., 1919, 729A), which is burnt on; the metal is then treated with zinc chloride solution or other solution which acts in a similar manner, and finally subjected to a rolling operation in the bath of the molten coating metal.—A. R. P.

Hardening of articles made of wrought iron; Process for the superficial —. J. Jönsson, Hamburg. Ger. Pat. 317,087, 9.12.17.

WROUGHT iron or other iron low in carbon may be hardened superficially by heating it in contact with small pieces, flakes, or powder of iron rich in carbon (such as cast iron) and a flux until the cast iron melts.—A. B. S.

Ores; Treatment of —. F. Krupp A.-G. Grusonwerk, Assignees of W. Kauffmann, Magdeburg-Buckau, Germany. Eng. Pat. 109,271, 1.9.17. (Appl. 12,590/17.) Int. Conv., 15.9.15.

ORES are calcined or roasted in a revolving cylindrical furnace, to which air is admitted through a series of tuyeres distributed along its length in such a way that the amount of air admitted through each tuyere corresponds to the amount of fuel to be burnt in the vicinity. By this means complete roasting is effected without any sintering taking place and without the application of external heat even if the ore is poor in combustible constituents.

—A. R. P.

Zinc solutions; Purification of —. S. Field, and The Metals Extraction Corporation, Ltd., London. Eng. Pats. (a) 138,946, 22.5.18, (b) 138,950, 25.6.18, and (c) 138,951, 16.11.18. (Appls. 8535, 10,708, and 18,832/18.)

(A) Impure zinc sulphate solution is heated to 80°–100° C. and treated with ozonised air in the presence of a metallic oxide, hydroxide, or carbonate to aid in the precipitation of the metals to be removed. The solution is agitated during treatment. The use of a mixture of manganese dioxide and lead dioxide produced in the electrolysis of a zinc

solution with lead anodes is recommended. (b) Two metals in contact, neither of which is identical with any foreign metal to be removed, are introduced into the solution to be purified. One metal is electro-negative to the metals to be removed and the other either the metal of the solution or electro-positive thereto. Generally the amalgam of the metal forming the base of the solution to be purified is used. The solution is preferably acidified and heated to 70°–100° C. (c) Zinc sulphate solutions containing copper are purified from nickel, copper, and cadmium by agitating at 80°–100° C. with zinc fume or "blue powder" in the presence of a small quantity of acid. The nickel is reduced to 0.5 part per million or less. If the solution is free from copper a small quantity of a soluble copper salt is added. Further acid is added to the zinc solution as required during purification. The zinc may be revived for re-use by washing with a dilute acid.—T. H. Bu.

Zinc solutions; Purification of — H. L. Sulman, S. Field, and The Metals Extraction Corporation, Ltd., London. Eng. Pats. (A) 138,947, and (b) 138,948, 28.5.18. (Appls. 8331-2/18.)

The neutral impure zinc sulphate solution is freed from iron, arsenic, antimony, copper, and cadmium, and then treated (a) with zinc fume or "blue powder" (preferably first washed with acid) at 80°–100° C., whereby the nickel content is reduced to 0.5 part per million or less; and (b) with lead peroxide or manganese dioxide, or a mixture of both (e.g., the mud obtained from electrolytic cells during the deposition of zinc from manganiferous zinc solutions with lead anodes) at 80°–100° C., which reduces the cobalt to the order of 0.5 part per million, or less.—T. H. Bu.

Zinc; Production of good, workable — from inferior material. Siemens-Schuckertwerke G.m.b.H., Siemensstadt. Ger. Pat. 301,335, 9.10.15.

Impure zinc may be freed from sulphur, oxygen, lead, iron, cadmium, and arsenic by heating it to a temperature at which it melts but does not volatilise or oxidise appreciably, and then passing steam or carbon dioxide through it or treating it with charcoal or wood.—A. B. S.

Zinc and other metals; Refining — W. Nestmann, Köln-Kalk. Ger. Pat. 317,511, 1.1.19.

The metal is purified by fusing it and allowing it to stand for a long time in the molten condition. Specifically heavier impurities separate during the solidification of the metal, and after removing these the metal is again fused to allow of the separation of other impurities.

Zinc alloy; Production of a — F. Kammerer, Pforzheim. Ger. Pat. 308,527, 9.12.17.

An alloy of high melting point, moderate hardness, and considerable tenacity and high resistance to compression is obtained by mixing 91–98 parts of zinc with 2–6 parts of copper and manganese, the manganese itself amounting to 0.5–1.7 parts.—D. F. T.

Alloy. F. M. Becket, Assignor to Electro-Metallurgical Co., Niagara Falls, N.Y. U.S. Pat. 1,333,151, 9.3.20. Appl., 26.9.19.

An iron alloy containing 10–45% of chromium, 3–25% of manganese, 0–3% of carbon, and 0–3% of silicon is machinable, resists oxidation at high temperatures, has a low magnetic permeability, and responds readily to heat treatment.—T. H. Bu.

Alloy; Metal — J. B. Grenagle, Catonsville, Md., Assignor to The Rare Metals Reduction Co. U.S. Pat. 1,334,089, 16.3.20. Appl., 16.7.17.

An alloy containing Zr 6.8%, Cr 53.5%, and Ta 39.7%.—T. H. Bu.

Alloy for backing electrotypes and for the manufacture of type metal. M. Schlötter, Berlin-Wilmersdorf. Ger. Pat. 316,369, 27.8.16.

THE tin of the usual lead-antimony-tin alloy is replaced wholly or in part by mercury and the antimony by a suitable smaller quantity of arsenic. An alloy containing Pb 99.4%, As 0.4%, and Hg 0.2% is capable of giving the same number of impressions as one containing Pb 75%, Sb 18%, and Sn 7%.—D. F. T.

Metal; Process of drawing refractory — J. Hisamoto, Nagoya, and Toyo-Kagaku-Yakin-Kabushiki-Kaisha, Tokyo, Japan. Eng. Pat. 139,065, 23.4.19. (Appl. 10,169/19.)

A BAR of refractory metal, e.g., tungsten, is surrounded by a refractory oxide in a metal tube, from which air and moisture are exhausted. The tube, raised to a suitable temperature, is hammered and worked and then drawn into a filament, the tube metal and oxide being finally removed from the core of refractory metal.—T. H. Bu.

Lead; Refining — T. H. Leathart, and Locke, Blackett and Co., Ltd., Newcastle-on-Tyne. Eng. Pat. 140,278. (Appls. 13,597, 25.5.19, and 17,785, 16.7.19.)

ZINC, arsenic, antimony, and other volatile impurities are removed from lead by treating the molten metal with sodium or with phosphorus, mercury, and potassium, or each separately, and then heating the mixture to redness or blowing air or steam, or both, through it. An alloy of 99 parts of lead with one part of the purifying agent is preferably prepared and then one part of one or more of these alloys is added to fifty parts of the lead to be treated.—A. R. P.

Solder for metals, particularly aluminium. R. Iversen, Christiania. U.S. Pat. 1,332,899, 9.3.20. Appl., 27.10.19.

THE solder is composed of tin, zinc, copper, aluminium, and manganese.—T. H. Bu.

Aluminium; Soldering substance for — with process for obtaining it. A. M. Ayala, Madrid. U.S. Pat. 1,333,237, 9.3.20. Appl., 8.3.19.

A solder for aluminium, having a fusion point varying from 180° to 250° C., is composed of 37–43% of zinc, 37–42% of tin, and 17–24% of lead.—T. H. Bu.

Ores; Process of concentrating — J. T. Terry, jun., Assignor to Terry Mining and Metallurgical Corp., Salt Lake City, Utah. U.S. Pat. 1,334,420, 23.3.20. Appl., 16.1.19.

THE powdered ore is treated in water containing a metal-ammonia salt, and the concentrate is recovered by flotation.—B. N.

Copper; Method and apparatus for precipitating — from hot solutions. F. Laist, Anaconda, Mont. U.S. Pat. 1,333,985, 16.3.20. Appl., 8.9.19.

A COPPER-BEARING material is leached with an acid solution, and the copper-rich solution is impregnated with sulphur dioxide and heated to precipitate the copper. The steam is used to preheat another quantity of solution.—T. H. Bu.

Sulphidation and flotation of minerals. J. W. Thompson, Superior, Ariz., and J. T. Terry, jun., Salt Lake City, Utah, Assignors to Metals Recovery Co., New York. U.S. Pat. 1,334,720, 23.3.20. Appl., 16.11.16.

SULPHIDATION of ores preparatory to flotation is carried out in an apparatus consisting of a number of centrifugal pumps, means for feeding the ore pulp to the first of the pumps, and means

for supplying hydrogen sulphide between the pumps so that it is intimately mixed with the pulp.
—J. W. D.

Sulphidation and flotation of ores. J. W. Thompson, Superior, Ariz., Assignor to Metals Recovery Co., New York. U.S. Pat. 1,334,721, 23.3.20. Appl., 16.11.16.

OXIDISED ores which have been sulphidised by the action of a soluble sulphide are subjected to a preliminary aeration treatment before flotation.
—J. W. D.

Concentrating oxidised ores by sulphidation and flotation. Concentrating oxidised ores by flotation. J. M. Callow and J. T. Terry, jun., Salt Lake City, Utah, and J. W. Thompson, Superior, Ariz., Assignors to Metals Recovery Co., New York. U.S. Pats. (a) 1,334,733 and (n) 1,334,734, 23.3.20. Appl., 16.11.16 and 25.11.16.

THE ore pulp is subjected to (a) a combined sulphidising and frothing agent treatment, or (n) a preliminary treatment with a frothing agent, followed by sulphidation, and the resulting sulphidised pulp is subjected to a froth-flotation process.—J. W. D.

Furnace; Smelting —. A. Jones, Los Angeles, Cal., Assignor to U.S. Smelting Furnace Co., Belleville, Ill. U.S. Pat. 1,334,459, 23.3.20. Appl., 28.5.17.

THE furnace consists of a cylindrical body with removable conical ends, both the furnace and the ends being lined with refractory material. The inner part of each end carries a supporting track for rotating the furnace, and the outer part is provided with a central opening.—J. W. D.

Roasted ores containing copper, zinc, silver, etc. [e.g. chloridised pyrites cinders]; *Process for leaching* —. W. Braumüller, Duisburg. Ger. Pat. 309,161, 2.5.15. Addition to 307,648 (this J., 1919, 910 A).

THE hot roasted mass is made into a pulp with a little of the leaching liquid, and run into movable vessels (trucks or vats), from which it is transferred as required to the leaching tanks. By this means loss of material is avoided and the distributing device can be either dispensed with or replaced by a simple cone.—A. R. P.

Pyrites cinder; Process and kiln for chloridising-roasting of —. J. Simon, Frankfurt. Ger. Pat. 317,601, 3.8.17.

PYRITES cinder is mixed with salt and 0–2% of coke breeze and fed into an air-tight shaft-kiln, and air is blown through it in an upward direction. The kiln may have two grates, one of which rotates so as to ensure continuous removal of the roasted product and thus increase the output of soluble copper with a minimum quantity of salt.—A. B. S.

Manganiferous slags and ores; Process for working up — by wet chlorination. Farbenfabr. vorm. F. Bayer and Co., Leverkusen. Ger. Pat. 309,278, 30.9.17.

MANGANESE ores or slags are heated at a high temperature under pressure with a solution of ferrous chloride (e.g. spent pickling liquor). The manganese dissolves as chloride, while iron is precipitated (compare Ger. Pat. 307,174; this J., 1919, 951 A).—A. R. P.

Electric arc welding, cutting and repairing [using alternating current]. C. J. Holslag, South Orange, N.J., U.S.A. Eng. Pat. 126,271, 14.11.18. (Appl. 18,689/18.) Int. Conv., 30.4.18.

Roasting of ores or concentrates. U. C. Tainton, Martinez, Cal., U.S.A. Eng. Pat. 140,943, 13.6.19. (Appl. 14,989/19.)

SEE U.S. Pat. 1,310,455 of 1919; J., 1919, 643 A.

Roasting furnace. F. Fouarge, Swansea. U.S. Pat. 1,335,490, 30.3.20. Appl., 24.4.17. Renewed 4.2.20.

SEE Eng. Pat. 102,595 of 1916; J., 1917, 142.

Electric blast-furnace. J. Bibby and J. O. Boving, Assignors to Electro-Metals, Ltd., London. U.S. Pat. 1,336,017, 6.4.20. Appl., 16.1.19.

SEE Eng. Pat. 132,616 of 1918; J., 1919, 867 A.

Zinc solutions; Purification of —. H. L. Sulman and S. Field, Assignors to The Metals Extraction Corporation, Ltd., London. U.S. Pat. 1,336,386, 6.4.20. Appl., 12.5.19.

SEE Eng. Pat. 138,948 of 1918; preceding.

XI.—ELECTRO-CHEMISTRY.

Electric furnaces; Step induction regulator for —. P. B. Short. Trans. Amer. Electrochem. Soc., 1920, 35—42. [Advance copy.]

A DETAILED description is given of an electrical control equipment recently designed for twenty electric furnaces in Norway, consisting of a combination induction-type regulator, a selector switch, a transfer switch, a series transformer, and a suitable panel for meters and switches.—B. N.

Electrolysis of alkali salts. Van Laer. See VII.

Ferrates. Grube and Gmelin. See VII.

PATENTS.

Primary galvanic batteries with unalterable electrolyte. E. W. Jungner, Kneippbaden, Sweden. Eng. Pat. 118,843, 30.8.18. (Appl. 14,106/18.) Int. Conv., 4.9.17.

AN electropositive porous carbon electrode having one surface exposed to the air, and a substance, capable of facilitating depolarisation by the oxygen of the air, deposited on this surface, is floated on the electrolyte, so that the air-depolarising substance is only partly soaked by the liquid. The electrode may be made in the form of a frame containing pieces of electrically conducting carbon, with plates or ribs pressed against the carbon pieces by springs serving as terminals for the electrode. An oxide of a metal (Cu, Ag, Mn, Hg) may be used as the depolarising substance. The cell may be covered by a porous cover, admitting air to the air-depolarising substance, but preventing or delaying evaporation from the electrolyte. The electro-negative electrode may be composed of zinc, iron, tin, lead, or aluminium in an electrolyte of a sodium or potassium salt, or iron, tin, or lead in an ammonium salt electrolyte, the latter also containing not more than 10% of an alkali metal or ammonium hydroxide or carbonate. The metal combines with the acid radical of the electrolyte, whilst a soluble alkali hydroxide is also formed, which transforms the electronegative metal into an insoluble hydroxide, regenerating the original electrolyte. The metallic electrode may consist of a horizontal grate with vertical parallel bars or ribs connected together, the limbs being of different length, and with an extension outside the cell for manually imparting a shaking motion to the electrode so as to remove the deposited metallic hydroxide.—B. N.

Moulded articles [insulators, resistance blocks, etc.]; Manufacture of —. The British Westinghouse Electric and Manufacturing Co., Ltd., London. From Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa., U.S.A. Eng. Pat. 124,669, 10.9.18. (Appl. 14,722/18.)

DRY hydraulic cement is mixed with a dry fusible impregnating material, such as resin or pitch, preferably coumarone or indene-resin, with or without addition of asbestos and barytes or other inert filler; the mixture is wetted, moulded, allowed to set, and then heated to fuse the impregnating material.

Electro-osmotic process for removing water from materials. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Eng. Pat. 135,817, 25.6.18. (Appl. 10,455/18.) Int. Conv., 20.10.17.

WATER is removed electro-osmotically from vegetable, animal, or mineral substances by first treating the material, which is to be dried, with the water-containing electrolyte flowing away from material under electro-osmotic treatment; or the material may be brought to the osmotic apparatus in the form of a thin magma, by washing it from its natural bed by a jet of water obtained from the liquid flowing away from material under electro-osmotic treatment.—B. N.

Displacement of liquids in materials [e.g., nitrocellulose] by other liquids, by the aid of electro-osmosis; Process for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pats. (A) 305,512, 18.3.17, (B) 307,701, 6.6.17, and (C) 307,702, 21.6.17.

(A) THE material to be treated is subjected to the action of the electric current between electrodes, the displacing liquid being introduced at one electrode and the displaced liquid removed at the other. The material is separated from the electrodes by diaphragms. The process is accelerated by the use of electrolytes, viz., by those containing OH-ions if the liquid moves towards the cathode and by those containing H-ions if it moves towards the anode. In displacing water from nitrocellulose by alcohol, for example, alcohol is fed in at the anode, and the displaced water collects at the cathode, both electrodes being perforated. The cellulose bodies for which the process is particularly suitable, are, for electro-osmotic purposes, almost without exception electro-negative, so that the process is favourably influenced by the addition of a small quantity of ammonia, caustic soda, etc. (B) The displacing liquid is introduced and the displaced liquid removed at places corresponding to the specific gravities of the respective liquids. For example, the displaced fluid is drawn off at the lowest point if its specific gravity is greater, and at the highest point if its specific gravity is lower, than that of the displacing fluid. (C) The displacing fluid is cooled before use, enabling stronger currents to be employed without the risk of attaining dangerous temperatures.—J. S. G. T.

Electro-osmotic dehydration of animal, vegetable, and mineral substances; Process for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,444, 14.2.18.

A MOVING electrode is employed which serves also as a conveyor for the material to be treated. The electrode may be in the form of an endless band, which is periodically displaced relatively to the other (stationary) electrode, for the purpose of filling the dehydration space, and relatively to a scraper or to the material itself for purposes of emptying. The band electrode is also provided with a suitable cut-out for purposes of emptying.—J. S. G. T.

Electro-osmotic dehydration apparatus; Process for feeding material to be treated in —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,494, 21.10.17.

THE material to be treated is fed along those electrodes at which liquid is removed, the feed opening being placed adjacent to this electrode, or the channels for feeding the material passing through the electrodes. The fresh material thus meets a very fluid mass of material, which opposes very little resistance to its passage, and the layer of dehydrated material is not disturbed.

—J. S. G. T.

Electro-osmotic dehydration apparatus. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,495, 21.10.17.

DISTANCE pieces in the form of pegs, frames, etc., and insulated from one of the electrodes, are disposed between the electrodes. The channels for conveying the material to be treated may serve also as distance pieces, being for this purpose mechanically attached to the electrode at which the dried material is separated.—J. S. G. T.

Electro-osmotic dehydration of vegetable, animal and mineral materials; Apparatus for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,496, 21.10.17.

THE material to be treated is subjected to treatment in a so-called chamber-press, the plates of which are employed as electrodes, one or both of these being of a permeable nature. The frames are provided with channels covered with filter-cloth or wire gauze and connected to an outlet channel.

—J. S. G. T.

Electrodes for electro-osmotic purposes; Double —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Ger. Pat. 316,593, 21.10.17.

A GRID of corrugated sheet iron is covered on both sides with a thin removable layer of wire gauze. Alternatively, two perforated metal sheets may be connected by bolts or the like and covered on both sides with wire gauze.—J. S. G. T.

Electrodes for electric furnaces. Det Norske Aktieselskab for Elektrokem. Ind. Norsk Industri-Hypotekbank, Christiania. Eng. Pat. 137,811, 8.9.19. (Appl. 22,068/19.) Int. Conv., 17.1.19.

AN electrode consisting of a metallic casing filled with a carbonaceous mass (see Eng. Pats. 116,853 and 119,018; this J., 1918, 429 A, 661 A) is heated to a comparatively low temperature, preferably in the furnace in which it is to be used, part of the heat being generated by current passed into the mass through the metal casing. Internal ribs, with or without projections on the casing, ensure good electrical contact between the internal mass and the casing, and the latter is provided also with holes through which the gases, evolved during the baking, escape. The casing is made in sections, so that as the lower part is consumed a fresh section may be added to the top containing the stamped electrode mass.—B. N.

Electrode. K. Tornberg, Lynn, Mass., Assignor to General Electric Co. U.S. Pat. 1,334,820, 23.3.20. Appl., 28.8.18.

THE electrode comprises a metal tube, a film of water-glass on the inner surface thereof, a filling of magnetite mixture in the tube, and a seal on the top of the filling consisting of a solidified button of plastic material having about 0.5% of anhydrous potassium fluoride incorporated in it.—B. N.

Carbon electrodes; Production of a strong protective coating for —. Ges. für Teerverwertung-m. b. H., Duisberg-Meiderich. Ger. Pat. 316,450, 6.11.17.

A coating which does not flake off at the temperature of the electric furnace is produced by treating the electrodes after baking, and while hot, with a mixture of metallic oxides and water-glass or like substance.—J. S. G. T.

Electric furnaces. E. Fenton, Loughborough. Eng. Pat. 139,843, 21.6.19. (Appl. 21,831/18.)

A VERTICAL electric furnace comprises a stationary base and a body portion adapted to be rotated relatively to the base, the latter being provided with a discharge opening through which the material is uniformly fed downwards by rotation of the upper portion. The upper and lower portions are separated by a water-seal into which flows water projected on to the furnace for cooling purposes; the overflow passes over the outer surface of the base of the furnace. To ensure uniform clearance at the adjacent extremities of the upper and base portions of the furnace, a circular lining consisting of detachable segmental plates is provided.—B. N.

Electric furnace. P. de Miles, New York. U.S. Pats. (A) 1,317,863 and (B) 1,317,864, 7.10.19. Appl., 25.1.18.

(A) A CRUCIBLE of electrically resistant material is supported by a number of spaced electrodes, which in turn are supported by arms, and means are provided for exerting pressure on the electrodes to cause them to make good contact with the crucible. (B) An electrical resistance rod extends through a hollow casing and is engaged by spaced electrode terminals, and means, insulated from the electrodes, are provided for exerting pressure on the electrodes to ensure good contact with the resistance rod.

Electric furnace. W. K. Booth, Assignor to The Booth Electric Furnace Co., Chicago, Ill. U.S. Pat. 1,332,795, 2.3.20. Appl., 3.2.19.

THE furnace body, with contact members mounted on it, is supported so that it can turn on an axis, adjustable electrode clamps being supported on the ends of the furnace body and engaging the electrodes extending through the ends. The contact members are connected with the clamps by flexible conductors supplying current through a second set of contact members engaging the first-named contacts.—B. N.

Electric furnace and method of operation. L. C. H. Groeger, Chicago, Ill. U.S. Pat. 1,333,914, 16.3.20. Appl., 5.4.19.

THE heating chamber of the furnace is provided with a hearth terminal and a number of co-acting side electrodes which extend towards each other from the sides, and are so disposed above the bath as to enable an arc to be established directly between their inner ends. The electrodes may be tilted, and an arc may be established directly between the electrodes, or between the electrodes and the bath, with the circuit completed through the hearth terminal.—B. N.

Electric furnace. M. R. Trembour, Watervliet, N.Y., Assignor to Ludlum Electric Furnace Corp., Albany, N.Y. U.S. Pat. 1,333,950, 16.3.20. Appl., 24.3.16.

THE furnace is provided with a melting hearth, ovoid in plan, and with a dish bottom constricted towards the opposite ends of its major axis, where doors are placed for charging and discharging. A removable low arched roof, similar to the hearth in shape, is provided with arches at the opposite

ends of its major axis, thus completing the door openings. Vertically-adjustable electrodes, passing through the roof, are arranged along the major axis of the furnace.—B. N.

[Electric] furnace for endothermic gas reactions [e.g., oxidation of nitrogen]. Elektrochem. Werke, G.m.b.H., Berlin. Ger. Pat. 316,349, 24.3.17. Addition to 268,410.

THE gases, after passing through the hot zone between the electrodes, are conveyed through a long, water-cooled tube constructed of a thin material which is a good conductor of heat and of such a diameter that the velocity of the gases through the tube is several hundred metres per second. The temperature is reduced almost instantaneously by about 1000° C., and a nitric oxide concentration of 2.5% is attained.—L. A. C.

Electrochemical reactions in gases and vapour by means of the alternating discharge; Process and apparatus for effecting —. H. Spiel, Vienna. Ger. Pat. 317,502, 19.7.18. Int. Conv., 19.7.17.

AN absorbing liquid functions as one or other of the electrodes or as an auxiliary electrode. The arc is struck between a liquid surface and a tubular electrode through which a brisk stream of drops flows. Electrolytic decomposition of the absorbing liquid is prevented by employing current of frequency above 500 per sec. In this manner air may be converted into an aqueous solution of nitric acid. In similar manner, by discharge of oxygen in the presence of organic or inorganic liquids, oxidation processes may be effected, and hydrogenation and chlorination similarly in presence of hydrogen and chlorine respectively. Organic substances may be synthesised by the discharge of carbonaceous gases or vapours over water and other liquids.—J. S. G. T.

Electrolytic cell. U. C. Tainton, Johannesburg, Transvaal. U.S. Pat. 1,334,419, 23.3.20. Appl., 5.11.18.

THE cell comprises a casing consisting of a number of ring sections secured together, with a fixed electrode, provided with a central opening, secured in the interior of each alternate casing. A shaft, extending through the casing, is journaled in and insulated from the head members, and electrodes are secured on the shaft at points intermediate of the fixed electrodes. A rotary motion is given to the shaft and electrodes carried by it. Means are provided for passing an electrolyte from one end of the casing to the other. Each fixed electrode is enclosed in, but spaced from, a fabric covering, forming a chamber about each fixed electrode for the reception of an electrolyte, and preventing the circulating electrolyte from mixing with the one about the fixed electrodes and from coming in contact with the latter.—B. N.

[Electrolytic] oxygen and hydrogen generator. G. Miller, Los Angeles, Cal. U.S. Pat. 1,334,668, 23.3.20. Appl., 17.6.19.

A CELL member, open at one end and closed at the other, made of non-metallic, non-conducting, non-absorbent material and having a transverse partition, is mounted in a receptacle containing an electrolyte with the open end downwards, the transverse partition being spaced slightly above the floor of the container, and electrodes are mounted within the chambers with a gas conduit leading from each of them.—B. N.

Electro-osmotically removing liquids from materials; Apparatus for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.), Berlin. Eng. Pat. 135,818, 25.6.18. (Appl. 10,457/18.) Int. Conv., 20.10.17.

XII.—FATS; OILS; WAXES.

Oils and fats; Purification of —. B. Lach.
Oel u. Fettind., 1919, 1, 363—364, 389—391,
414—416. Chem. Zentr., 1920, 91, 11., 251.

VARIOUS fats and oils can be purified by treatment with nascent hydrogen (zinc and acid). A white product may thus be obtained from dirty tallow, and the method gives good results with distilled olein. Rancid fats may be rendered fit for use by boiling them with live steam, and treating them while boiling with 1 to 2% of alum, which is added, little by little, as a concentrated solution. The fat is neutralised etc. after an hour. The method is applicable to bone fat, margarine, etc.—C. A. M.

Soap; Analysis of —. Weber. Seifens.-Zeit., 1919, 46, 652. Chem.-Zeit., 1920, 44, Rep., 98.

For factory control water in soap is best determined by Fahrion's method (J., 1910, 1065) when carbonates are absent, but for the analysis of filled soaps, lubricating soaps, and soap powder distillation with xylene gives the best results. Free alkali is determined by Davidsohn's method, a solution of the soap in 60—70% alcohol being treated with barium chloride, and then titrated with standard acid without filtering. Alkali carbonate is determined by direct titration of a 50% alcoholic solution of the soap, and deducting the amount of acid neutralised by the free alkali. In determining the fatty acids by extraction with ether, the ethereal solution is left for 12 hours over dehydrated sodium sulphate, and then filtered, and the residual sodium sulphate washed with ether. In the case of soaps containing coconut or palm-kernel oils, Goldschmidt's method is used. After evaporation of the ether, 2 to 3 grms. of the fatty acids is titrated with N/2 alcoholic alkali solution, and the result calculated on 1 gm. of fatty acids. Four grms. of the soap is then dissolved in sodium silicate solution, and treated with hydrochloric acid, the fatty acids extracted with ether, the ethereal solution washed with sodium chloride solution and evaporated, and the residue dissolved in about 55 c.c. of neutral alcohol and treated as described.—C. A. M.

Myricyl alcohol; Brodie's —. A. Gascard.
Comptes rend., 1920, 170, 886—888.

By careful analysis of the corresponding iodide and comparison of the alcohol, iodide, and corresponding saturated hydrocarbon with known adjacent members in the same series, it is shown that the myricyl alcohol obtained from beeswax has the formula $C_{31}H_{63}OH$. (Cf. J. C. S., June.)—W. G.

PATENTS.

Fats, oils, and waxes and their acids; Process for decolorising —. Vereinigte Chem. Werke A.-G., and K. Lüdecke, Charlottenburg. Ger. Pat. 317,448, 22.1.18.

FATS or the like, after hydrolysis of the neutral constituents, are treated with chlorine, and the products are hydrolysed by heating in the absence of water with the addition of substances capable of absorbing hydrochloric acid. The product is distilled with superheated steam under reduced pressure, yielding a fat free from odour and suitable for use in soap manufacture.—L. A. C.

Lipase; Manufacture of preparations containing —. R. Willstätter, Munich. Ger. Pat. 317,503, 25.9.18. Addition to 316,504 (J., 1920, 306 A).

LIPASE is absorbed from emulsions or suspensions by large seed-shaped granules of pumice stone, wood or animal charcoal, diatomite, or the like.—L. A. C.

Liquids or solutions insoluble in water; Process for dissolving or emulsifying —. Chem. Fab. Flörsheim, Dr. H. Noerdlinger, Flörsheim. Ger. Pat. 314,017, 19.12.15.

SULPHONATED compounds prepared according to Ger. Pat. (J., 1920, 164A) are employed for emulsifying or rendering miscible with water liquids which in themselves are immiscible therewith. Mineral or fatty oils mixed with the sulphonated compounds can be used as drilling oils or lubricants. Disinfectant liquids are made with mixtures of these compounds with phenols or tar oils; laundry or fat-removing liquids by combining them with hydrocarbons of the aromatic series or with chloro derivatives of aliphatic or aromatic hydrocarbons; and with various other substances, mixtures useful in the textile, dyeing, and leather industries are prepared.—J. F. B.

Tar soap; Manufacture of —. W. Schmidt, Elberfeld, and E. Heuser, Darmstadt. Ger. Pat. 316,258, 15.3.18.

WOOL-, lignite-, or coal-tar is extracted with water to dissolve volatile organic acids, and is then saponified to prepare a tar soap. The aqueous extract is evaporated to remove the volatile acids, and the dissolved tar, which separates as a syrupy liquid, may also be saponified.—L. A. C.

Washing and cleaning; Process for —. K. Horkenbach, Duisberg. Ger. Pat. 317,402, 13.9.17.

A DETERGENT is used containing sodium carbonate or a mixture of sodium carbonate and water-glass, together with 1 to 5% of a dried extract from peat or humic coal. The extract is prepared by treating the peat or humic coal with water or an alkaline or acid solution, either at the usual or high temperatures, and under either normal or reduced pressure, separating insoluble matter, and evaporating the colloidal solution obtained.—L. A. C.

Catalysts. U.S. Pat. 1,335,161. See I.

Fatty acids from wood tar, etc. Ger. Pat. 315,417. See III.

Linsced oil substitute. Ger. Pat. 317,731. See XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Carbon black; its properties and uses. G. St. J. Perrott and R. Thiessen. J. Ind. Eng. Chem., 1920, 12, 324—331.

Most of the carbon black now manufactured in the United States is made by the "channel" system, in which the black from natural gas is deposited upon the smooth under-surface of steel channels by means of burners 3 to 4 in. below them. The channels are arranged in tables of eight, and are given a slow reciprocating motion whereby the deposited black is scraped from them into hoppers. The quality of the product varies with the amount of air, the speed of scraping, and the pressure of the gas. In accordance with the conclusions of Bone and his co-workers (J., 1915, 786), gases rich in ethane and higher homologues give greater yields of carbon by this method. The temperature of the channels is maintained at about 300° C. At the present time only relatively small quantities of lampblack are used for printers' ink, and then only in admixture with carbon black. Carbon black is used in rubber mixings and in the paint trade; its sp. gr. is 1.8 and it has a greater tinting and covering capacity than any other black. *Testing methods:* The tinting strength and colour are estimated by comparison with a standard black, the former with a mixture of the black and zinc oxide and the latter with the black itself, in both cases mixed with oil. Chemical tests include those for moisture, ash, and acetone extract. An acetone extract exceeding 0.1% indicates adulteration with a poorly calcined lampblack. A sample containing more than 0.2% ash is probably adulterated with mineral black or charcoal. Most blacks for ink contain 2—4% moisture, though certain kinds may contain up to 7%. Some blacks will absorb as much as 15% of their weight of moisture. Specifications are suggested for printing ink, rubber, and paint. The use of the torsion viscosimeter will indicate the behaviour of a black in practice. When equal weight of blacks with the same amount of raw linseed oil are tested by means of MacMichael's apparatus (J., 1915, 1226), the lowest readings are given by those kinds valued by ink makers for their "length." *Chemical analysis:* Carbon blacks contain 85—95% amorphous carbon, 1—7% water, 0.5—0.8% hydrogen, and 2—8% oxygen (partly as CO and CO₂, partly as fixed oxygen). A black yielding a "long" ink is usually low in carbon and high in volatile matter and oxygen, whilst "shorter" blacks show the reverse. Typical analyses are given. As a rule, "long" blacks are more hygroscopic than "short" blacks. They may also be distinguished microscopically in freshly-prepared mixtures with their lithographic varnish, "short" blacks gradually agglomerating into groups of 20 to 100 particles, whereas the particles of "long" blacks remain completely dispersed after several hours.—C. A. M.

Finger-prints. Mitchell. See XXIII.

PATENTS.

White [antimony oxide] pigment; Manufacture of —. A. L. Barbe, Asnières, France. Eng. Pat. 140,301, 24.7.19. (Appl. 18,392/19.)

ANTIMONY oxide obtained by roasting the sulphide is separated and introduced as an aqueous suspension into a vat fitted with agitators. An alkaline solution, preferably lime, is then added, the mixture well agitated, and a current of oxygen or compressed air forced in by means of a pipe fitted to the lower part of the vat until any sulphite present is eliminated.—A. de W.

Painting and priming compositions; Manufacture of —. Flakes A./S., and E. Schou, Copenhagen. Eng. Pat. 140,147, 4.1.19. (Appl. 290/19.)

PAINTS or priming compositions are prepared by gradually adding oleaginous materials, e.g., drying oils, varnishes, solutions of waxes or tars, etc., to a thin,ropy, aqueous solution of emulsifying ingredients, i.e., a thin solution or fine mixture of starch, casein, glue, gums, or the like which is kept in constant motion, the emulsion being thereafter treated by homogenising machinery so that the particles of the oleaginous material are reduced to a minutely divided state (diam. 10 μ or less). Further proportions of oil or water, or pigment prepared in oil or water, may be added without destroying the emulsion.—A. de W.

Resins and turpentine; Recovery of — from resinous woods. W. H. Sawyer, Auburn, Me. U.S. Pat. 1,331,679, 23.3.20. Appl., 26.2.19.

CHIPS of resinous woods are treated so as to break down the cellular structure without reducing the fibre length, and extracted with a cold volatile alkaline solvent, the latter being then separated from the wood and the alkali volatilised.—A. de W.

Resin-emulsions; Preparation of —. Badische Anilin- und Soda-Fabrik, Ludwigshafen. Ger. Pat. 307,123, 23.1.17.

ARTIFICIAL resins and resin-like substances such as condensation products of formaldehyde with aromatic compounds are dissolved in high-boiling organic solvents, and these solutions intimately mixed with soap solutions. The formaldehyde-naphthalene condensation product (Ger. Pat. 207,713; J., 1909, 431) gives with monochlorobenzene and Turkey-red oil, a fine emulsion of the consistency of ointment which is miscible with water to a milk-like translucent liquid, but requires the addition of gelatin or similar substance to form dilute preparations.—B. V. S.

Resin soaps; Manufacture of —. O. Braemer, Hamburg. Ger. Pat. 317,344, 2.3.18.

NEEDLES or other portions of conifers containing turpentine are treated with oxidising agents and saponifying agents, such as alkalis, either consecutively or simultaneously. The oxidising agent, e.g., sodium peroxide or percarbonate, swells and opens up the plant tissue and promotes the extraction of resin. In the treatment of ground fir needles the cellulose constituents may be allowed to remain in the soap as a filler. The brown colour of the soap may be removed by bleaching agents.—J. F. B.

Artificial resin; Manufacture of an —. C. C. Bohler, Dresden. Ger. Pat. 317,267, 19.9.18.

ANHYDROFORMALDEHYDEANILINE, either alone or with the addition of a small percentage of organic or inorganic acids and alkalis, is heated to 100°—200° C., and a vulcaniser, such as sulphur chloride, is added either during the period of heating or to the final product.—L. A. C.

Linseed oil; Substitute for —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 317,731, 8.5.17.

A SUBSTITUTE for linseed oil is made from the products of condensation or polymerisation of aldol, acetaldehyde, crotonaldehyde, or other aldehydes, in presence of alkalis, sodium acetate, etc. The products yield elastic, glossy lacquers, especially in the presence of driers.—A. B. S.

Pencil drawings on paper; Fixation and blackening of —. A. Grimert, Weimar. Ger. Pat. 317,441, 11.5.19.

THE paper is placed between metal plates or rollers

and subjected to electrolysis, water being a satisfactory electrolyte for the purpose.—W. J. W.

Plastic luting composition; Manufacture of a —. Gebr. Heyl und Co. A.-G., Charlottenburg. Ger. Pat. 317,138, 13.11.17.

A PLASTIC luting composition is composed of naphthenic acids and an oxide of a heavy metal, e.g., iron oxide.—L. A. C.

Recovering solvents [from coatings on aeroplane parts etc.]; Apparatus for use in —. E. I. du Pont de Nemours and Co., Assignees of T. Baker, Wilmington, Del., U.S.A. Eng. Pat. 123,752, 20.2.19. (Appl. 4276/19.) Int. Conv., 19.1.18.

Hydrocarbons. Ger. Pats. 309,281-2. See XX.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Action of certain organic accelerators in the vulcanisation of —. G. D. Kratz, A. H. Flower, and C. Coolidge. J. Ind. Eng. Chem., 1920, 12, 317—324.

THE accelerating effect of certain substances such as diphenylthiourea is due to their tendency to decompose under the vulcanisation conditions into simpler substances containing an active nitrogen group to which the acceleration is attributable. The same accelerating influence is shown by substances containing the same active nitrogen group in their primary nucleus, if these are used in molecularly equivalent quantities. For example, the activity of diphenylthiourea is practically equal to that shown by an amount of aniline corresponding to the quantity formed in the decomposition of the former. The activity of the parent substance is reduced by replacing the hydrogen in the active nitrogen group by other and larger groups. The activity of the nitrogen in certain groups is most readily explained on the assumption that the valency of the nitrogen is increased from the trivalent to the pentavalent condition, with the temporary addition of sulphur.—C. A. M.

PATENTS.

[Rubber] composition for use as floor covering and method of manufacturing same. W. Stocks, Fitzroy, Victoria. Eng. Pat. 121,136, 29.11.18. (Appl. 19,763/18.) Int. Conv., 27.10.17.

Rubber; Method of reclaiming —. D. F. Twiss, Assignor to The Dunlop Rubber Co., Birmingham. U.S. Pat. 1,335,926, 6.4.20. Appl., 6.12.18.

Colouring fibrous material. U.S. Pats. 1,332,974 and 1,332,982. See VI.

Piperidine piperidylthiocarbamate. Ger. Pat. 316,009. See XX.

XV.—LEATHER; BONE; HORN; GLUE.

Glue jellies; Testing the strength of —. W. H. Low. J. Ind. Eng. Chem., 1920, 12, 355—356.

A MODIFICATION of Smith's glue tester consists essentially of a U-tube containing mercury covered with a layer of coloured water and provided with an adjustable scale on one limb. The other limb is extended at right angles and then bent downwards and is connected to a rubber pressure bulb, whilst a vertical capillary tube extending downwards and terminating in an inverted thistle funnel covered with a rubber diaphragm, is fused to the middle of the extension. Steady pressure is applied

to the bulb until the water in the capillary tube is forced downwards from an initial to a final mark, and the height of water in the U-tube is then read on the scale. The glue jelly in a glass vessel is then fixed against the rubber diaphragm by means of a movable support, and the force required to drive the water between the two points on the capillary tube again measured, the figure previously found for the rubber diaphragm alone being deducted. The method is sensitive and gives concordant results, which enable glues to be graded with comparative accuracy.—C. A. M.

Glue; Determination of the tensile strength of —. G. Hopp. J. Ind. Eng. Chem., 1920, 12, 356—358.

THE glue is melted, poured into moulds of polished iron, 12 in. square and $\frac{1}{4}$ in. deep, and allowed to set. The glue-sheet is dried on fine-meshed wire round which the air can circulate, and the drying completed under pressure while protected from air currents. Strips about 7 in. long, and with an average thickness of 0.1 in. and width of 0.33 in., are cut from the sheet, and the tensile strength determined by means of a Schopper machine. The average tensile strengths of commercial glue used in three different factories were respectively 13.24, 8.52, and 11.57 lb. per sq. in.—C. A. M.

PATENTS.

Condensation products [tanning substances] from aminohydroxynaphthalenesulphonic acids and formaldehyde; Production of —. Deutsch-Koloniale Gerb- und Farbstoff-Ges. m.h.b., Karlsruhe. Ger. Pat. 315,871, 11.6.14. Addition to Ger. Pat. 313,523 (Eng. Pat. 18,174 of 1913; J., 1917, 93).

CONDENSATION between 2 mols. of a salt of an aminohydroxynaphthalenemono- or di-sulphonic acid and about 1 mol. of formaldehyde in aqueous solution, if necessary with the addition of an acid, is effected more rapidly and completely if the mixture is heated to boiling than at ordinary temperatures.

Emulsifying liquids. Ger. Pat. 314,017. See XII.

Karaya gum compositions. U.S. Pats. 1,334,356-8. See XVII.

XVI.—SOILS; FERTILISERS.

Lime; Action of — in the soil. J. Hughes. J. Bath and W. and S. Counties Soc., Vol. 13. Reprint. 11 pages.

QUICKLIME was mixed with four times its weight of soil and exposed in the air-dried state indoors and in the moist state outdoors. Two types of soil were used containing respectively 3.85% and 14.97% of organic matter and combined water. In both cases where the material was exposed in the moist state the whole of the lime was carbonated within six weeks. With eleven Herefordshire soils it was found that, in every case where the magnesia was in excess of the lime, full crop results could not be obtained.—W. G.

Phosphates; Decomposition of — with bisulphate [for the production of superphosphate]. B. Neumann and K. Kleylein. Z. angew. Chem., 1920, 33, 74—77.

WHEN sulphuric acid above 47.5° B. (sp. gr. 1.49) is saturated with bisulphate, the acidity of the solution is diminished, but with weaker acids the bisulphate increases the acidity. Bisulphate can, therefore, only be used advantageously with the weaker acids. In the preparation of super-

phosphate from natural phosphate, the best yield of soluble phosphoric acid, about 92% theory, was obtained with acid of 48° B. (sp. gr. 1.498) when the theoretical quantity of sulphuric acid was used, whilst when $\frac{1}{2}$ of the theoretical quantity of acid was used, the yields were fairly constant at 68 to 72% with acids varying from 31.3° to 53° B. (sp. gr. 1.277–1.58). When, however, a mixture of $\frac{1}{2}$ of the theoretical quantity of acid and a quantity of bisulphate equivalent to the remaining $\frac{1}{2}$ was used, the yield increased with decreasing strength of acid, reaching a maximum of 88.6% with acid of 31.3° B. (sp. gr. 1.277). The use of bisulphate is likely to affect unfavourably the physical properties of the superphosphate, particularly when the natural phosphate used contains a high proportion of calcium carbonate.—E. H. R.

Calcium cyanamide; Inorganic impurities in crude —. J. Baumann. Chem.-Zeit., 1920, 44, 275–276.

MAGNESIA in particular, and in lesser degree silica, disturbs the working of the electric furnace. Sulphur decreases the yield of ammonia obtainable from calcium cyanamide by removing nitrogen as thiocyanate; it might be profitable to increase the sulphur content materially if thiocyanate were recovered as a by-product. The residue of lost nitrogen is found in the autoclave sludge. During the oxidation of ammonia to nitric acid silica is deposited upon and poisons the platinum catalyst if silicon hydride is present (cf. Ger. Pat. 276,720; J., 1915, 28).—A. E. D.

Nitrate nitrogen and commercial organic nitrogen; Relative availability of —. Field and cylinder experiments. A. W. Blair. J. Ind. Eng. Chem., 1920, 20, 262–264. (See also Lipman and Blair, J., 1918, 521 a.)

CYLINDER experiments, extending over 7 years, on the relative efficiency of sodium nitrate and dried blood in loam soil and in mixtures of loam with 10–100% of coarse sand, showed that the superiority of the nitrate was well maintained until the proportion of sand amounted to about 70%. Only when the proportion of sand was 100% did the crop yield (dry substance) from blood exceed that from nitrate. In field plot trials extending over two 5-year rotations the average yield of dry substance for the five-year periods was 500 lb. per acre more from sodium and calcium nitrates than from organic nitrogen (dried blood, fish, and tankage). The average nitrogen recovery of all the nitrate plots for the 10 years was 37.4% as compared with 26.5% for the organic fertiliser plots. —J. H. L.

Chloropierin and higher plants. Bertrand. See XIXb.

PATENTS.

[Calcium] cyanamide; Process for granulating —. L. L. J. Barbé, Saint Maurice, France. Eng. Pat. 140,331, 1.10.19. (Appl 24,039/19.) Int. Conv., 21.3.19.

COARSELY-DIVIDED crude calcium cyanamide is reduced in a crusher to pieces of the size of an egg, then freed from carbide by treatment with water, and the pieces reduced to granules of the required size by means of crushing stamps, the formation of powder being avoided as far as possible. The granules are coated with powdered calcium cyanamide in a suitable machine and finally passed through sieves.—W. J. W.

Boiling and drying organic matter, more particularly slaughterhouse waste; Process for —. K. Niessen, Munich. Ger. Pat. 317,818, 7.2.15.

THE material is heated in a closed vessel surrounded

by a steam jacket. After vapours have ceased to be evolved from the material, steam is shut off from the jacket and turned on to a second jacket surrounding the first. Simultaneously fresh air is passed through a jacket surrounding the outer steam jacket into the inner vessel, the necessary cocks etc. being all appropriately turned by one operation, to effect the desired flow of steam and air.—J. S. G. T.

XVII.—SUGARS; STARCHES; GUMS.

Calcium salts; Removal of — from carbonated [beet sugar] juices. V. Stanek. Z. Zuckerind. Czechoslov., 1919, 44, 45–47, 53–58.

CARBONATATION alone is incapable of removing all the calcium salts of organic acids present in beet juices, and the addition of sodium carbonate or sulphite is advised. Better results were obtained when the sodium carbonate or sulphite was added before the completion of carbonatation, and also when both the first and second saturations were carried out at boiling point. A further improvement was effected by increasing the amount of calcium carbonate precipitated, especially at the second saturation, the amount of calcium sulphate and colloidal calcium salts thrown down thus being increased. Taking advantage of these observations, and without adding more sodium carbonate or sulphite than that equivalent to the calcium salts present in the juice, it was possible to reduce the calcium content present after clarification to at least 2 mg. per 100 c.c.—J. P. O.

Beet-sugar after-product massecuites; Ammoniacal frothing of —. K. Urban. Z. Zuckerind. Czechoslov., 1919, 44, 21–24.

DURING the 1918–19 campaign the author noticed that an after-product beet massecuite sometimes frothed considerably after being 24 hrs. in the coolers, carbon dioxide and also ammonia being evolved. The phenomenon is attributed to “frothy fermentation,” the carbon dioxide being produced by reaction between the invert sugar and the amino-acids (Maillard, J., 1912, 144), and the ammonia being formed by the decomposition of the ammonium salts of amino-acids during concentration and crystallisation. After the massecuite had remained in the coolers for about 48 hrs., and the temperature had fallen to 70°–75° C., the frothing subsided.—J. P. O.

Ammonia evolved during clarification and evaporation [in the beet sugar factory]; Recovery of the —. E. Donath. Z. Zuckerind. Czechoslov., 1919, 44, 61–64.

AMMONIA is constantly present in the steam arising from the liming and carbonatation tanks, the heaters, and the evaporators of the beet sugar factory. According to the author's estimate, the amount of ammonium sulphate that might be recovered in the clarification department alone in the case of a plant slicing 6000 quintals of roots in 24 hrs. is 3827 kg. per day. Recovery might be effected by absorption in towers, after first partially cooling the vapour and then passing it over caustic lime; or the process of separation as ammonium sulphite in a centrifugal fan might be applied (cf. Ger. Pat. 281,095; J., 1915, 612).—J. P. O.

Sucrose; Examination of Herzfeld's double polarisation method of determining —. R. F. Jackson and C. L. Gillis. Facts about Sugar, 1920, 10, 90.

MEASUREMENTS of the rate of decomposition of invert sugar in the presence of hydrochloric acid at different temperatures lead the authors to conclude

that the time of heating prescribed in the Herzfeld method of determining sucrose (viz., 3–5 min. while raising to 68°–70° C., and 5 min. at 69° C.) is the cause of considerable error. They believe a total period of 4½ min., and a temperature of 60° C., to be sufficient, which conditions necessitate the re-establishment of the factor for calculating the result. When applying the double polarisation method to products containing much invert sugar, an error arises owing to the conditions of the direct and inversion readings not being comparable, the direct reading being made in the presence of basic lead acetate, and the second in that of hydrochloric acid. Since, however, certain neutral salts (e.g., sodium chloride) affect the rotation of invert sugar in the same direction as hydrochloric acid, it is proposed to add a suitable amount of sodium chloride to the solution used for the direct reading, the inversion reading being taken in the presence of hydrochloric acid as usual.—J. P. O.

Sucrose; Double polarisation methods for the determination of — and a suggested new method. G. W. Rolfe and L. F. Hoyt. J. Ind. Eng. Chem., 1920, 12, 250–253.

THE difference between the inversion constant for the Herzfeld conditions (142.66° V.) and for the invertase method (141.7° V.) is due to the influence of the acid on the rotation of the invert sugar, and if the acid is neutralised before the inversion reading the difference becomes still greater. Inversion with very dilute acids at high temperatures gives constants closely approaching that for the invertase method, but the cooled inverted solution takes hours to attain a constant rotation. As the result of a study of mono- and trichloroacetic acids as hydrolytic agents, the authors suggest that the following method, which enables the direct and inversion readings to be made on solutions of the same acidity and sugar-content, and which, tested on low-grade Cuban sugars and a refinery syrup, gave results much nearer to those obtained by the invertase method than the Herzfeld procedure gave. A solution of the normal weight of the sample is clarified with basic lead acetate, made up to 100 c.c. and filtered, as usual. For the direct reading 50 c.c. is transferred to a 100 c.c. flask, treated with 15 c.c. of a 20% solution of monochloroacetic acid, made up to volume, and polarised within 15 mins. after the addition of the acid. For inversion, about 50 c.c. of this acidified solution, transferred to a 50 c.c. flask which is then tightly stoppered by tying down the cork, is heated in vigorously boiling water for 30 mins., or for 60 mins. if a large quantity of lead acetate has been used for clarification. The solution is afterwards cooled and allowed to stand for at least 2 hours before being polarised. The constant 141.0 is used in calculating the sucrose. Excess of basic lead acetate equivalent to 1 c.c. in a half-normal sugar solution does not affect the inversion nor produce troublesome precipitates. The solution does not darken during inversion to the same extent as under the conditions prescribed by Herzfeld.

—J. H. L.

Sucrose; Determination of — in cane molasses by Walker's double polarisation method. A. Brodie. Int. Sugar J., 1920, 22, 174.

WALKER'S method (J., 1917, 153) has been found to give results that are 0.3–0.5% lower than the truth, due mainly to the hydrolysis of sucrose by the excess of phosphoric acid in the liquid used for the direct reading at laboratory temperature. Half the quantity of phosphoric acid (i.e., 10 instead of 20 c.c. of a 10% solution) gives results that are correct within the limit of experimental error. Horne's solid basic lead acetate with which clarification is effected may contain sufficient moisture to cause an appreciable error.—J. P. O.

Sugar; Effect of concentration on the deteriorative activity of mould spores in —. N. Kopeloff, S. Byall, and L. Kopeloff. J. Ind. Eng. Chem., 1920, 12, 256–257. (See also this J., 1919, 592 A.)

IN mixtures of blackstrap molasses with different proportions of sugar syrup of 60° Brix, inoculated with spores of various moulds, the amount of sucrose inverted during storage for 4 months at 23°–30° C. was found to vary with the "moisture ratio," i.e., percentage of mixture/(100–polarisation). In pure sterilised sugar coated with similar mixtures in a centrifuge, so as to give moisture ratios ranging from 0.08 to 0.2, and heavily inoculated, the invert sugar-content increased in all cases (in some cases four-fold) during one month's storage, and in general to a greater extent the higher the moisture ratio, but irregularities were observed attributable to differences in the degree of inoculation and the amount of syrup mixture on the crystals. *Aspergillus Sydowi*, *Bainier*, *A. niger*, and *Penicillium expansum*, in the order named, produced the greatest deterioration.—J. H. L.

Bagasse; Deterioration of — on keeping. C. Janssen. Archief Suikerind. Nederl.-Indië, 1919, 37, 1974–1975. Int. Sugar J., 1920, 22, 169.

Loos and Schweizer (Archief, 1919, 27, 1772–1775) found the sucrose content of bagasse to diminish at a rapid rate. After 3 hours, for example, the sucrose content had fallen from 3.17 to 1.77%, and after 6 the polarisation of the extract was 0°. This observation is not confirmed by the author, who was unable to observe any diminution in the sucrose content of bagasse after keeping it at the prevailing laboratory temperature for 8 hours.—J. P. O.

PATENTS.

Sugar cane juice or the like; Apparatus for filtering —. A. Azpiazu, Habana, Cuba. U.S. Pat. 1,332,877, 9.3.20. Appl., 14.10.18.

THE apparatus comprises a series of conical filtering surfaces, arranged one above another, an inclined receiving bottom with a discharging channel for the filtrate below each filtering surface, and conduits for discharging the filtration residue from one filtering surface to the next below it through the intermediate receiving bottom.—J. H. L.

Decolorising liquids; Process for — especially sugar juices. Verein der Zuckerindustrie in Böhmen, Prague. Ger. Pat. 317,449, 1.8.17.

THE decolorising medium, e.g., carboraffin (Staneek, J., 1919, 192 A), or similar substance, is deposited from a mixture with water, dilute sugar solution, etc., in the frames of a filter-press, through which the liquid to be treated is then passed in the usual way.—B. V. S.

Karaya thickener and process of making the same. Dried soluble karaya-gum composition and process of making. Casein composition. H. V. Dunham, Meunt Vernon, N.Y. U.S. Pats. (A) 1,334,356, (B) 1,334,357, and (C) 1,334,358, 23.3.20. Appl., (A) 19.7, (B) 26.11, and (C) 25.3.19.

(A) KARAYA gum is dissolved in water containing a quantity of sodium bicarbonate equal to about 3% of the weight of the gum, and the solution is dried. (B) Karaya gum is soaked in water containing a small quantity of a weak alkali, a lacteal fluid is then added, and the mixture dried. (C) A composition containing soluble casein and soluble karaya gum.—L. A. C.

Dextrin and other modified starch products; Manufacture of —. H. C. Gore, Takoma Park, Md. U.S. Pat. 1,335,162, 30.3.20. Appl., 21.6.19.

A SUITABLE amount of acidulated water is added to a quantity of starch, together with a small amount

of dextrin to act as a binder; the mixture is formed into an open mass, dried, and dextrinised in a current of warm air.—A. B. S.

VIII.—FERMENTATION INDUSTRIES.

Fructose [levulose]; Fermentation of — by *Lactobacillus pentoaceticus*, N. Sp. W. H. Peterson and E. B. Fred. J. Biol. Chem., 1920, 41, 431—450.

THIS organism will decompose levulose with the formation of acetic acid, lactic acid, carbon dioxide, and considerable amounts of mannitol. The latter substance is, however, itself attacked if the fermentation is prolonged, and the final products are then acetic and lactic acids and carbon dioxide. It is feasible that an intermediate stage in the decomposition is represented by malic acid.—J. C. D.

Acetone and butyl alcohol fermentation of starch by Bacillus granulobacter pectinovorum. H. B. Speckman. J. Biol. Chem., 1920, 41, 319—343. (Cf. J., 1919, 155 τ .)

THE starch is converted into dextrose by an exoenzymic action. The dextrose then passes into the cells and is oxidised to acetic and butyric acids, which are reduced in part to the corresponding alcohols. The origin of the acetone is regarded as not proven.—J. C. D.

Red wines and fruit juices; Acidimetry of —. A. M. Macmillan and A. Tingle. J. Ind. Eng. Chem., 1920, 12, 274—276.

THE acidity of red wines may be determined in presence of phenolphthalein as indicator by using the spectroscope to ascertain the end-point (cf. J., 1918, 117 τ , 443 A). Other coloured liquids may be titrated in a similar way, but the details of procedure must be adapted to individual cases. The method may be used also with methyl red; 100 c.c. of liquid containing 3 c.c. of a 0.05% solution of this indicator, when viewed through a depth of 45—50 mm., shows in presence of acid a strong absorption band in the green, which disappears sharply when the neutral point is reached.

—J. H. L.

Vinegar; Determination of oxalic acid in —. A. Bau. Daut. Essigind., 1919, 23, 358—361, 366—368. Chem. Zentr., 1920, 91, II., 298.

THE author's calcium acetate reagent (J., 1918, 524 A, 671 A) gives far more reliable results than a saturated solution of calcium sulphate, and can be applied without previously neutralising the vinegar. Normal fermentation vinegar contains no oxalic acid, but this may be formed if over-oxidation has taken place. Commercial acetic acid may contain glyoxalic acid, which forms oxalic acid on oxidation. The quantity of oxalic acid in such a case is too small to be detected by the calcium sulphate reagent, but can be found by the calcium acetate reagent.—J. F. B.

Bacteria and hydrocarbons. Tausz and Peter. See IIIA.

Preservatives. Perry and Beal. See XIXB.

PATENTS.

Sauce and process of making the same [from soya beans]. S. Satow, Sendai, Japan. U.S. Pat. 1,332,448, 2.3.20. Appl., 5.5.17.

A MIXTURE of soya bean, roasted grain, water, and koji is "fermented," alcoholic or other harmful fermentations being prevented, e.g., by addition of common salt, and the filtered liquid is evaporated to dryness in vacuo.—J. H. L.

Fermented beverages; De-alcoholising —. G. B. Sippel and G. J. Patitz, Assignors to P. Schoenhofen Brewing Co., Chicago, Ill. U.S. Pat. 1,333,457, 9.3.20. Appl., 8.2.18.

THE hot fermented beverage, mixed with a heated current of gas, is introduced in a finely divided form into a de-alcoholising chamber, where it encounters cross currents of a heated inert gas. The finely divided liquid is maintained throughout at a temperature approaching 100° F. (38° C.).—J. H. L.

Yeast; Manufacture of —. Verein der Spiritus-Fabrikanten in Deutschland, Berlin. Ger. Pat. 303,311, 21.12.15.

THE yeast used for pitching worts prepared from sugar or molasses and mineral salts, is purified by a fermentation of the same nutrient solution, in which the mineral acid liberated in the course of fermentation is allowed to accumulate, calcium carbonate being added only when the yeast has been purified by the acid liberated. The acidity necessary for purification is about 0.125%.—J. H. L.

Mash filtration; Apparatus for —. J. G. Crossman, Watford. Eng. Pat. 140,946, 30.6.19. (Appl. 16,421/19.)

XIXA.—FOODS.

Proteins of barley, oats, rye, and wheat kernels; Nutritive value of the —. T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1920, 41, 275—306.

THE proteins of the entire kernel of these grains are adequate for growth and more efficient than those of the endosperms.—J. C. D.

Corn [maize] gluten meal; Nutritive value of commercial —. C. O. Johns, A. J. Finks, and M. S. Paul. J. Biol. Chem., 1920, 41, 391—399.

COMMERCIAL maize gluten meal supplemented by dried brewers' yeast, whole ground yellow maize, or coconut press-cake furnishes the necessary protein for normal growth of rats. Eighteen per cent. of whole, ground, yellow maize-meal furnishes sufficient water-soluble vitamins for normal growth.

—J. C. D.

Corn [maize] and corn meal; Cause of deterioration and spoiling of —. J. S. McHargue. J. Ind. Eng. Chem., 1920, 12, 257—262.

WHOLE grain containing 12% of moisture can be kept in good condition for at least 12 months if absorption of further moisture is prevented. In moist air it absorbs water, and when it contains 15% moulds develop at the ordinary temperature and under conditions of restricted ventilation, and rapid deterioration ensues. Alcoholic and acetic fermentation takes place when the moisture-content amounts to 20%. Flour made from whole grains undergoes an increase of acidity when exposed to the air, but with a moisture-content of 12% it may be kept suitable for human consumption for 4—6 months, provided moisture and air are excluded. Dried flour undergoes little or no increase of acidity, especially at low temperatures. Flour made from grain previously freed from embryos, with a moisture-content of 12%, may be kept for 12 months when air and moisture are excluded, without acquiring any musty or sour flavour, the only change which occurs being a gradual increase in acidity, confined mainly to the oil, but the removal of the embryos greatly diminishes the nutritive value of the grain. Some particulars are given of the kinds of mould found growing on spoiled maize.—J. H. L.

Kennet powder; Preparation of —. O. Gratz. *Molkerei-Zeit.*, 1913, 29, 273—274, 279—280. *Chem. Zentr.*, 1920, 91, II., 299.

RENNET extracts were made either with 5% sodium chloride solution or with 0.2—0.3% hydrochloric acid, and were preserved with formaldehyde or toluene. The best precipitating agent was sodium chloride, which was added to the strongly acid extract almost to saturation. The slimy precipitate, of yellowish-grey colour, settled only slowly. Occasionally a portion floated as a fine scum. The product was dried at 30°—35° C. under reduced pressure. The organic portion was rich in chymosin. The powder could be re-dissolved in water, and its enzyme activity and solubility were increased by a second precipitation, although the yield was considerably reduced. In the first precipitation 15—20 g. of dry powder was obtained from 1000 g. of extract.—J. F. B.

Hydrocyanic acid content of Phaseolus lunatus beans. H. Lührig. *Chem.-Zeit.*, 1920, 44, 262.

THE enzyme occurring naturally in *Phaseolus lunatus* beans liberates the whole of the hydrocyanic acid when the beans are mashed with water (J., 1920, 277A); the addition of saliva does not increase the quantity (prolonged action decreases it), and no further quantity is obtained when the distillation residue is treated with emulsin, saliva, bile, or pancreatic juice.—W. P. S.

Fruit juices. Macmillan and Tingle. See XVIII.

Preservatives. Perry and Beal. See XIXB.

Action of chloropierin on wheat parasites. Piutti. See XIXB.

PATENTS.

Potatoes and the like vegetable substances; Process for the economical desiccation of —. Wauquier et Cie., Lille, France. Eng. Pat. 122,422, 15.1.19. (Appl. 1083/19.) Int. Conv., 15.1.18.

THE material, converted into a finely divided form by shredding, crushing, or otherwise, is freed from as much water as possible in centrifugal separators of the imperforate, non-filtering drum type, and finally completely dried by a known method. Four-fifths of the water present in fresh potatoes can be removed by the centrifugal treatment.—J. H. L.

Meat; Dry and soluble extract of raw —. A. Chalas, Paris. Eng. Pat. 129,639, 8.7.19. (Appl. 17,070/19.) Int. Conv., 10.7.18.

THE liquid plasma of meat is separated by pressure from the muscular fibrin, and evaporated in a high vacuum at a very low temperature, to exclude bacterial development. Evaporation may be effected in bulk, and if necessary in two successive evaporators, or by means of drying rollers provided with scrapers, inside the vacuum chamber, or by injecting the plasma into the chamber in a finely divided form, in which case electric lamps in the upper part of the chamber may be used to replace the heat lost by evaporation. Dehydrating agents, such as sulphuric acid, calcium chloride, or zinc chloride, are preferably used to absorb the moisture evaporated. Soluble products, such as albumoses, may be prepared from the muscular fibrin, e.g., by the action of pepsin or papain, and added to the plasma in the course of or after desiccation.—J. H. L.

Meat-like preparations; Manufacture of —. P. Hildebrandt, Hamburg, Germany. Eng. Pat. 139,525, 31.1.18. (Appl. 1816/18.)

ANIMAL or vegetable refuse containing proteins, e.g. fish waste, cartilage, horn, hair, oil-cake, etc., is treated with oxidising agents such as permanganates, chromates, ozone, hydrogen peroxide, or

per-salts, and afterwards hydrolysed by boiling with strong mineral acids for several hours.—J. H. L.

Meat juice preserves; Manufacture of —. Nobel und Co., Hamburg. Ger. Pat. 309,180, 6.12.17. Addition to 307,135 (J., 1920, 78A).

IN order to curtail the cooling process and to prevent the development of odours, hydrogen peroxide is added to the mixtures containing meat, salt, vegetables, and milk powder before the cooling process. The hydrogen peroxide is decomposed by enzymes with liberation of oxygen, which effects the conversion of the mixture more rapidly than air.—J. F. B.

Milk; Process of making a substitute for —. A. B. Moses, Seattle, Wash. U.S. Pat. 1,332,562, 2.3.20. Appl., 19.5.19.

A MIXTURE of flour derived from the seed of leguminous plants and water is heated at about 160° F. (71° C.), filtered, and then heated practically to the boiling point to precipitate proteins.—J. H. L.

Bran and the like; Apparatus for extracting from — their nutritious components. L. C. Reese, Saginaw, Mich. U. S. Pat. 1,334,552, 23.3.20. Appl., 16.12.18.

IN a battery of intercommunicating extractors adapted to be worked in series at different temperatures, each extractor is connected to means for heating its contents to the temperature required for the series worked at the higher temperature, and to means for cooling the extracting liquid on its passage to the series worked at the lower temperature, and means are also provided for maintaining the temperature uniform in this series.—J. H. L.

Egg substitute; Manufacture of —. H. S. Cullen and G. L. Fulton, Wellington, N.Z. Eng. Pat. 120,396, 24.10.18. (Appl. 17,399/18.) Int. Conv., 2.11.17.

Artificial milk; Manufacture of —. K. Erslev, Nijmegen, Holland. Eng. Pat. 121,133, 28.11.18. (Appl. 19,673/18.)

Sauce. U.S. Pat. 1,332,448. See XVIII.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Sterilisation of — by ultra-violet rays. W. L. Decker. Cleveland Eng. Soc., Jan., 1920. *Chem. and Met. Eng.*, 1920, 22, 639—645.

WITH a quartz lamp at 66 volts, 3.5 amps., the time necessary to destroy various germs was determined. Less than 20 seconds is sufficient for *B. coli*. To obviate interference by suspended matter, even after filtration, it is advantageous to agitate the water during exposure to the rays, for which purpose a special apparatus with baffles has been devised. A graph is given which is a continuous record, over a period of 3 months, of the bacteria in the untreated, filtered, and sterilised water; the turbidity of the untreated and filtered water; the efficiency of bacteria removal in the filters; the rate of filtration; the hourly and daily consumption of water; the number of men working; the oxygen consumed in the raw water; the presence or absence of pathogenic germs in the treated water. If fresh bacteria are added to water which has been treated with ultra-violet rays, 90% of these succumb in an hour.—W. J. W.

[Sewage] *sludges; Action of activated — on the ammonia of sewage and of ordinary water.* Diénert and Girault. *Comptes rend.*, 1920, 170, 899—901. (Cf. J., 1920, 347 A.)

THE activated sludges prepared as previously de-

scribed (*loc. cit.*) cause the disappearance of ammoniacal nitrogen in an almost identical manner from sewage and from ordinary water the ammoniacal nitrogen content of which has been made equal to that of the sewage. As the sludge gets older the ratio of ammonia oxidised to time of disappearance at first diminishes and then increases. Nitrous nitrogen only appears after the sludge has been used for several months.—W. G.

Preservatives; Quantities of — necessary to inhibit and prevent alcoholic fermentation and the growth of moulds. M. C. Perry and G. D. Beal. J. Ind. Eng. Chem., 1920, 12, 253—255.

TEST-TUBES containing sterilised 2% dextrose meat broth were inoculated with *Sach. cerevisiae* and *Penicillium glaucum*. The following table shows approximately the percentages of various antiseptics required to prevent visible fermentation or mould growth and also the percentages required to destroy the organisms completely. In the case of alcohol the results differed according as the tubes were closed by a cap to prevent evaporation or not. The action of sodium benzoate appears to be due solely to the antiseptic properties of the free acid.

	<i>Sach. cerevisiae.</i> No gas evolved.	Organisms destroyed.	<i>Penic. glaucum.</i> No visible growth.	Organisms destroyed
Alcohol:				
Without cap ..	16	20	8	17
With cap ..	11	15	8	14
Sodium salicylate	1	9	3	5
Sodium benzoate	0.5	3	0.25	5
Sodium sulphite ..	0.6	above 12	or less above 12	above 12
Sodium bisulphite	0.25 or less	10	0.25 or less	6
Formaldehyde ..	0.25 or less	0.25 or less	0.25 or less	0.4

—J. H. L.

Chloropicrin; Action of — on the parasites of wheat and on rats. A. Piutti. Comptes rend., 1920, 170, 854—856.

A CLAIM for priority over Bertrand and his co-workers (J., 1919, 336A, 437A). 20 c.c. of chloropicrin per cub. m. of space, at 15°—20° C., proved effective for the destruction of wheat parasites, and the flour and bread made therefrom were quite inoffensive and retained all their nutritive power. For the destruction of rats in ships, a much lower concentration of chloropicrin than that used by Bertrand (*loc. cit.*) is effective.—W. G.

Chloropicrin; Action of — on the higher plants. G. Bertrand. Comptes rend., 1920, 170, 858—860.

At moderately high concentrations of chloropicrin (200 g. per cb. m.) the leaves of the trees examined were rapidly killed but remained fixed on the branches. At much lower concentrations (20 g. per cb. m.) marked plasmolysis was noticeable and finally the leaves softened, turned brown, and fell off. This effect diminished as the concentration was further diminished. Young leaves are less sensitive than old leaves, and the terminal ends are very resistant.—W. G.

Absorptive power of charcoal. Winter and Baker. See VII.

PATENTS.

Cresol preparations; Production of clear —. P. Borinski, Berlin. Ger. Pat. 315,016, 5.8.17.

CRESOL is mixed with an emulsifying agent, *e.g.*, concentrated sulphite-cellulose waste lye, and as much of a salt of an aromatic hydroxycarboxylic acid, *e.g.*, sodium salicylate, as is necessary to pro-

duce a clear mixture. Preparations containing up to 90% of cresol can be obtained as permanently clear liquids.—H. J. H.

Emulsifying liquids. Ger. Pat. 314,017. See XII.

Tar soap. Ger. Pat. 316,258. See XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Theobromine; Solubilities of —. R. V. Wadsworth. Analyst, 1920, 45, 133—131.

The high solubilities for theobromine recorded by Mitscherlich appear to have been due to the presence of caffeine as an impurity. The solubility of the pure alkaloid in various solvents was as follows: Ether at 15.5° C., 0.003; at b. pt., 0.003; trichloroethylene at 15.5° C., 0.020; at b. pt., 0.03; chloroform, 0.06 and 0.07; water, 0.06 and 0.70; and tetrachloroethane, 0.090 and 0.870%.—C. A. M.

Hexamethylenetetramine; Preparation of —. A. Sander. Z. angew. Chem., 1920, 33, 81.

THE formation of hexamethylenetetramine by cold treatment of an ammonium salt with excess of formaldehyde is not confined to ammonium carbonate (J., 1920, 279A), but occurs with most ammonium salts, and the reaction is, in fact, utilised for the estimation of ammonia. By the use of the carbonate, however, a purer product is more readily obtained.—W. J. W.

ββ'-Dichloroethyl sulphide. C. S. Gibson and W. J. Pope. Chem. Soc. Trans., 1920, 117, 271—278.

SULPHUR dichloride reacts with dry ethylene at 40°—50° C. according to the equation $2\text{CH}_2:\text{CH}_2 + \text{SCl}_2 = (\text{CH}_2\text{ClCH}_2)_2\text{S}$, but owing to the further rapid action of the dichloride on the product, the yield only amounts to about 50% of the weight of the sulphur dichloride taken, and a considerable proportion of impurity is present. A much purer, but otherwise identical, product is obtained in 90—98% yield by the action of ethylene on sulphur monochloride at temperatures up to 70° C., preferably at 55°—60° C. The absorption of the ethylene at the commencement is facilitated by adding about 5% of ββ'-dichloroethyl sulphide to the monochloride. When the absorption of ethylene abruptly ceases, the product is heated to 100° C. to redissolve the viscous deposit of sulphur which separates towards the end of the reaction. On subsequent cooling the sulphur is deposited in a compact crystalline form from which the dichloroethyl sulphide can readily be separated by decantation. Pure ββ'-dichloroethyl sulphide, colourless needles, m.p. 13°—13.5° C., is without action on aluminium, lead, brass, iron, bronze, zinc, or tin at ordinary temperatures, and on the first three metals at 100° C. It has sp. gr. 1.285 at 15°/4°, and $n_D^{15} = 1.53125$.—G. F. M.

Dichloroethyl sulphide; Action of water on —. C. Boulin and L. J. Simon. Comptes rend., 1920, 170, 815—818.

DICHLOROETHYL sulphide is slowly decomposed by cold water: $(\text{C}_2\text{H}_4\text{Cl})_2\text{S} + 2\text{H}_2\text{O} \rightleftharpoons [\text{C}_2\text{H}_4(\text{OH})]_2\text{S} + 2\text{HCl}$. The decomposition is accelerated by rise in temperature and increase in the amount of water present. It is retarded by the presence of acids and alkalis and by the products of decomposition. The solubility of dichloroethyl sulphide in cold water is 0.48 gm. per litre and it is increased by the presence of thiodiglycol.—W. G.

Liquids having constant boiling points; Certain binary and ternary mixtures of —. W. R. G. Atkins. Chem. Soc. Trans., 1920, 117, 218—220. THE undermentioned binary mixtures exhibit con-

stant minimum boiling points: Acetone—carbon tetrachloride, 55.9° C. at 763 mm.; methyl ethyl ketone—carbon tetrachloride, 73.8° at 760 mm.; methyl ethyl ketone—*tert*-butyl alcohol, 79.0° at 762 mm.; methyl ethyl ketone—*isopropyl* alcohol, 77.3° at 759 mm.; methyl alcohol—carbon bisulphide, 37.1° at 751 mm.; carbon tetrachloride—*tert*-butyl alcohol, 71.0° C. at 768 mm. The ternary mixture methyl ethyl ketone—carbon tetrachloride—water has a constant boiling point at 65.7° C. at 760 mm. with the composition 22.2%, 74.8%, and 3% of its constituents respectively. The mixture carbon tetrachloride (85%)—*tert*-butyl alcohol (11.9%)—water (3.1%) boils constantly at 64.7° C. and 768 mm. pressure.—G. F. M.

Nitriles; Preparation of unsaturated — by catalysis. A. Mailhe. Bull. Soc. Chim., 1920, 27, 226—229.

UNSATURATED aliphatic or aromatic nitriles, such as crotononitrile, oleonitrile, elaidonitrile, and cinnamonitrile may be prepared by passing the vapours of the esters of the corresponding acids along with ammonia over alumina at 480°–500° C. as previously described (J., 1920, 349A).—W. G.

Methylamine; Preparation of — from ammonium methyl sulphate. W. S. Denham and L. F. Knapp. Chem. Soc. Trans., 1920, 117, 236—247.

THE product of the action of heat on ammonium methyl sulphate always contains dimethylamine and trimethylamine in addition to methylamine (cf. Werner, Chem. Soc. Trans., 1914, 105, 2762). Under no conditions is more than 25–30% of the ammonia converted into methylamine. Support for the view that a state of equilibrium is attained in the reacting mass, expressed by the equations

is derived from the fact that methylamine is formed when a mixture of the sulphates of ammonium, dimethylamine, and trimethylamine are heated together. Moreover, by increasing the reacting mass of ammonium sulphate by heating 2 equivalents of it, or preferably ammonium benzenesulphonate because of its greater fusibility, with ammonium methyl sulphate the yield of methylamine is increased to nearly 50% of the theoretical.—G. F. M.

Chlorhydrins and glycols; Preparation of ethylene and propylene — from oil-gas. B. T. Brooks. Chem. and Met. Eng., 1920, 22, 629—633.

IN the treatment of olefines with hypochlorous acid, it is unnecessary to use solutions of greater concentration than 0.1% total hypochlorite, and formation of chlorhydrin is accelerated by increasing the solution of the gas in the aqueous solution by agitation or moderate pressures. The author employed an apparatus of the liquid-circulating type, the free hydrogen chloride being neutralised by soda ash, sodium bicarbonate, or borax. The formation of chlorhydrin was fairly rapid, until the solution contained about 5% chlorhydrins, after which it proceeded more slowly. Propylene reacts more readily than ethylene. With a larger apparatus, using about 600 lb. of chlorine and 1000 galls. of solution, at a temperature of 15° C., and under 75 lb. pressure, yields of 4.55–7.75% chlorhydrin were obtained from oil-gas containing 34–36% total ethylene and propylene. Graphs are given indicating the behaviour on distillation of 24% ethylenechlorhydrin solution and of 24% and 70% ethylene- and propylene-chlorhydrins mixed. The effect of saturating a 24% solution of the chlorhydrins with common salt is also shown. Nearly theoretical yields of glycol are obtained from ethylenechlorhydrin. By treatment of a 20.8%

aqueous solution of ethylene- and propylene-chlorhydrins with sodium bicarbonate, the yield was 81.5% of the theoretical; when sodium carbonate was used, only 74.2% was obtained. (Cf. J., 1919, 923A).—W. J. W.

Marsh gas [methane]; Interaction of chlorine and — under the influence of light. Conversion of methyl chloride to methyl alcohol and methyl acetate. J. R. H. Whiston. Chem. Soc. Trans., 1920, 117, 183—190.

THE photochemical reaction between chlorine and methane never stops at the first stage to give methyl chloride exclusively, but a mixture of all the chloromethanes is produced in which methylene dichloride and chloroform predominate. In a mixture of 2½ vols. of methane to 1 vol. of chlorine only 25% of the chlorine forms methyl chloride, and with equal volumes only 10–13%. Methyl chloride can be completely converted into methyl acetate by passing it over porous sodium acetate at 290°–297° C., whilst slaked lime at 300° C. converts it almost quantitatively into methyl alcohol.

—G. F. M.

Acetylene; Action of nitric acid on —. K. J. P. Orton and P. V. McKie. Chem. Soc. Trans., 1920, 117, 283—296.

ACETYLENE is readily absorbed by absolute nitric acid or mixtures of nitric and sulphuric acids. The rate of absorption is decreased by diluting the nitric acid, and increased by certain catalysts, and by increase of temperature. The above-mentioned conditions also largely determine the nature and proportion of the products, the most important being nitroform and other substances which on further nitration yield tetranitromethane, carbon dioxide, and other substances, including oxalic acid which cannot be converted into tetranitromethane. High (100%) or low (70%) concentration of nitric acid, low temperature (0°–15° C.), and certain catalysts, notably platinum and silver, favour the production of the oxalic acid type of product, whilst 95% nitric acid, a temperature of about 30° C., and notably the use of mercury as a catalyst, cause nitroform and allied substances to predominate. The addition of 0.3–0.4% of mercuric nitrate to the nitric acid practically eliminates oxalic acid etc. from the product, and increases the percentage of the carbon in the acetylene employed converted into nitroform etc., to about 30%, the remaining 70% going to carbon dioxide. Nitroform in the product represents only 80–85% of the total substances, which on heating the reaction mixture with fuming sulphuric acid to 90°–95° for 4 hours are converted into tetranitromethane. These other substances are not very stable, and when the object is the preparation of tetranitromethane it is important to proceed with the further nitration, or at least to add the fuming sulphuric acid without delay. On cooling the nitrating mixture tetranitromethane separates as an oil, or sometimes as crystals, and is isolated by extraction with carbon tetrachloride or by distillation. It has m.p. 13.75° C., and sp. gr. 1.65009 at 15.8° C. The best yield observed was 22.3 g. from 4.6 litres of acetylene and 90 c.c. of absolute nitric acid diluted to 95% with water, the absorption being carried out at 30° C. in the presence of mercuric nitrate.—G. F. M.

Oxalates; Specific colour reaction of —. V. Macri. Boll. Chim. Farm., 1920, 59, 73.

THE colour reaction for oxalates described by Caron and Raquet (J., 1919, 662A) was published earlier by the author (J., 1917, 1176) as a reaction for detecting manganese salts. Addition of an oxidising agent is unnecessary, since agitation of a hot solution of a manganese salt with a little alkali

causes absorption of atmospheric oxygen and formation of higher oxides of manganese, these giving the red coloration with an oxalate. The reaction is not given in acid solution.—T. H. P.

Mercury; Determination of — in organic compounds. A. Wöber. Z. angew. Chem., 1920, 33, 63–64.

THE mercury may be obtained in solution, in a suitable condition for its determination by Rupp's iodometric method (J., 1908, 1179), by heating 0.5 g. of the substance with sulphuric acid at 60° C. in a flask fitted with a tapped funnel and a delivery tube connected with a Peligot tube which is cooled with water; 1 c.c. of concentrated hydrogen peroxide solution is added, drop by drop, to the contents of the flask, and the heating is continued until a clear solution results and sulphur trioxide fumes appear in the Peligot tube. The solution is then cooled, diluted, treated with 1 g. of sodium chloride, neutralised with sodium hydroxide solution (sp. gr. 1.3), mixed with the rinsings from the Peligot tube, and diluted to 100 c.c.—W. P. S.

Myricyl alcohol. Gascard. See XII.

PATENTS.

Amines; Process of substituting halogens for the amino groups in aliphatic —. Chem. Fabr. Flora, Dübendorf, Switzerland. Eng. Pat. 132,245, 25.8.19. (Appl. 20,863/19.) Int. Conv., 31.8.18.

THE amino-groups of aliphatic amines may be replaced by chlorine or bromine by treatment at 50°–100° C. with a mixture of nitric acid (sp. gr. 1.4) and concentrated hydrochloric or hydrobromic acid respectively. The reaction is accompanied by vigorous evolution of nitrogen, and proceeds without appreciable formation of by-products. It is particularly applicable technically to the aliphatic amino-acids or their salts; for example, *l*-leucine yields *l*- α -chloro (or bromo) isobutylic acid.

—G. F. M.

Ethyl alcohol and ethyl acetate; Synthetic manufacture of —. P. V. H. Pascal, Angoulême, Franco. Eng. Pat. 140,115, 31.5.18. (Appl. 9019/18.) Int. Conv., 3.4.17.

ETHYL alcohol is obtained by the electrolytic reduction of acetaldehyde or paraldehyde in acid medium, preferably 5–10% sulphuric acid, in a cell divided by a porous diaphragm, the aldehyde being introduced into the cathode chamber in two stages, so that the cathodic liquid contains initially about 10%, and finally 30% or more of organic material. The cathode may be of lead, antimonial lead, or mercury, and a current density of 2–3 amps. per sq. decm. is employed, which is sufficient to maintain the temperature at about 40° C. Instead of using aldehyde, acetylene may be converted into alcohol in one operation by introducing the gas into the acid electrolyte containing a mercury salt, whereby hydration and reduction occur simultaneously. By increasing the temperature, the density of the current, the percentage of acid or aldehyde, or the duration of reduction appreciable quantities of secondary products are formed, such as butanediol-1,3, crotonyl alcohols, butyl alcohol, ethyl ether, etc., and by suitable selection of conditions one or more of these may be made to predominate. Similarly by diminishing the efficiency of the diaphragm ethyl acetate is formed by combination of the alcohol formed at the cathode with acetic acid formed at the anode. Oxygen or ozonised oxygen is obtained as a by-product in all these operations.—G. F. M.

Pentaerythritol; Treatment of solutions containing crude —. Rheinisch-Westfälische Sprengstoff-A.-G., Cologne. Ger. Pat. 298,932, 21.6.14.

A solution containing crude pentaerythritol is neutralised and concentrated; the calcium formate which separates from the hot solution is removed, and pentaerythritol crystallises as the solution cools.—L. A. C.

Monobromoacetone; Manufacture of —. Manufacture of monobromoketones. J. D. Riedel, A.-G., Berlin-Britz. Ger. Pats. (A) 298,944, 15.9.15, and (n) 298,953, 15.10.16.

SOLUTIONS of bromine in bromide liquors are added at raised temperatures to bromide liquors containing (A) acetone and bromoacetone, or (n) a ketone or mixture of ketones and bromoketones, prepared by neutralising the aqueous solutions obtained in previous preparations of monobromoacetone and monobromoketones respectively.—L. A. C.

Glycol; Production of — from ethylene. Chem. Fabr. Griesheim-Elektron, Frankfurt. Ger. Pat. 300,122, 22.2.16.

By avoiding prolonged contact of ethylene with the oxidising agent (potassium permanganate), *e.g.*, by applying the principle of counter-currents, and by avoiding the accumulation of manganese dioxide mud and other materials which would tend to retain glycol, an almost quantitative yield of the latter is obtainable. Ethylene produced by the catalytic hydrogenation of acetylene can be advantageously used, in which case the accompanying ethane is obtained as a by-product.—D. F. T.

Succinylsuccinic acid esters; Manufacture of —. R. Willstätter, Munich. Ger. Pat. 300,672, 27.1.17.

SUCCINYLSUCCINIC acid esters, for use in the synthesis of tropine derivatives, are prepared by electrolysis of neutral or feebly acid solutions of acetonedicarboxylic acid esters. The secondary potassium salt of acetonedicarboxylic acid ester, produced by the action of concentrated aqueous or alcoholic potassium hydroxide on acetonedicarboxylic acid ester, yields succinylsuccinic acid diethyl ester (colourless needles, m. p. 46°–47° C.) on electrolysis; this gives pyrrole derivatives, *e.g.*, *N*-methylpyrrolediacetic acid ester (prisms, m. p. 164° C.) on treatment with ammonia or amines. Acetonedicarboxylic acid monomethyl ester yields less readily the corresponding succinylsuccinic acid methyl ester, from which *N*-methylpyrrolediacetic acid dimethyl ester (needles, m. p. 170°–171° C.) is obtained.—L. A. C.

Rectification of ether; Apparatus for —. Maschinenbau-A.-G. Golzern-Grimma, Grimma. Ger. Pat. 305,172, 19.9.16.

THE formation of by-products, losses due to evaporation or deficient conversion of alcohol, and increase of pressure due to too rapid supply of ether vapour are prevented by providing an intermediate or compensating column furnished with a condenser, through which the crude ether vapour passes on its way to the rectifying column.

—J. S. G. T.

Hydrocarbons and organic oxygen compounds; Preparation of — from the chlorinated products of mineral oils. F. Bergius, Hanover, and L. Landsberg, Nuremberg. Ger. Pats. (A) 309,281, 23.9.13, and (n) 309,282, 26.4.16.

(A) THE chlorinated products are heated under pressure with dilute aqueous alkalis, whereby the chlorine is completely removed. Chlorinated paraffin hydrocarbons of sp. gr. 0.790 and containing approximately 25% Cl yield an oily, insoluble mixture of terpene-like hydrocarbons and oxygen

compounds which may be used as a substitute for oil of turpentine; the aqueous liquid contains phenolic and acidic products. (b) By using alkali carbonates instead of dilute caustic alkali the formation of charred or tarry products is avoided; catalysts such as copper or copper salts may be simultaneously applied. The oily product has a higher specific gravity than the material originally chlorinated, and may be used as a solvent, *e.g.*, for the recrystallisation of trinitrotoluene.—D. F. T.

Germ-free virus; Process for obtaining —. Quarzlampen-Ges.m.b.H., Hanau. Ger. Pat. 315,101, 4.6.14.

VACCINE virus, obtained by the process described in Ger. Pat. 314,859 (this J., 1920, 312 A), is mixed with a very dilute solution of a photo-dynamical substance and subjected to the action of chemically active rays. Accompanying micro-organisms are destroyed by about 5 minutes' treatment without damage to the virus. Methylene Blue, Methylene Violet, Nile Blue, phenazine, Neutral Red, phenosafranine, Fluorescein and several of its derivatives, acridine, and chrysophanic acid are among the dyes mentioned as suitable photo-dynamic substances, as well as chlorophyll, uranium salts, and iron salts.—B. V. S.

Piperidine piperidylthiocarbamate; Preparation of —. Farbenfabr. vorm. F. Bayer und Co., Leverkusen. Ger. Pat. 316,009, 12.10.17.

PIPERIDINE piperidylthiocarbamate, for use as a vulcanisation catalyst, is prepared by the action of carbon bisulphide on an aqueous solution of piperidine at a low temperature; the presence of the water moderates the reaction.—D. F. T.

Hog-cholera serum; Process of producing refined —. J. Reichel, Assignor to H. K. Mulford Co., Philadelphia, Pa. U.S. Pat. 1,335,986, 6.4.20. Appl., 3.4.14.

SEE Eng. Pat. 6604 of 1915; J., 1916, 653.

Acids from wood tar etc. Ger. Pat. 315,417. See III.

Cymene. U.S. Pat. 1,336,694. See V.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photomicrography with simple apparatus. T. J. Ward. Analyst, 1920, 45, 130—133.

For magnifications up to about $\times 4$ the camera is fitted with a short-focus (10 to 12 cm.) single meniscus photographic lens, whilst by placing a large diameter lens on a support between the camera lens and the object magnifications up to about $\times 8$ may be obtained. For magnifications up to about $\times 75$ the camera lens is replaced by a microscope objective fitted into a cork. For most purposes "ordinary" plates are the most suitable.

—C. A. M.

Action of coal upon a photographic plate. Sinkinson. See IIa.

PATENTS.

Strong [photographic] prints from weak negatives; Process for producing —. G. Staess, Berlin-Steglitz. Ger. Pat. 316,087, 1.5.17.

A THIN film of transparent gelatin or celluloid, coloured red by means of potassium ferric oxalate and ammonium thiocyanate, is interposed between the negative and the printing paper. This is bleached as printing proceeds in inverse proportion to the density of the negative, and the effect of printing under a steeper negative is obtained. The bleached film regains its colour on storing in the dark. The amount of intensification obtained may be reduced by partial bleaching of the film before printing or increased by using two or more films.

—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose from wood pulp. R. G. Woodbridge, jun. J. Ind. Eng. Chem., 1920, 12, 380—384.

DIFFICULTIES experienced in the nitration of wood pulp in crêpe paper form were that the nitrated material tended to gelatinise, and that this and the shortness of the fibre rendered it difficult to remove the acid from the nitrocellulose in the centrifugal wringer. The yield of nitrocellulose was very low, only about 1.2 lb. per lb. of wood cellulose, as compared with 1.52 lb. from cotton cellulose. The consumption of acid was high, and the material was difficult to dehydrate. The viscosity of wood pulp nitrocellulose was much lower than that of cotton nitrocellulose. It was found, however, that satisfactory results could be obtained by the use of mixtures of cotton fibre with at least 50% of wood pulp, the most suitable material being sulphite pulp from spruce or mildly bleached soda pulp from pine instead of a deciduous wood. The mixtures gave no material difficulty in nitration, the acid recovery was normal, and the yield of nitrocellulose about 1.50 lb. per lb. of cellulose, indicating a yield of about 1.48 lb. per lb. of wood cellulose. In preparing the nitrocellulose the dehydration required a somewhat longer time. For nitrating wood pulp alone additional purification would be essential, and would add to the cost of the product. (Cf. J., 1919, 555 A, 602 A.)—C. A. M.

Nitrocellulose and inorganic nitrates; Estimation of nitrogen in — with the nitrometer. E. G. Beckett. Chem. Soc. Trans., 1920, 117, 220—235.

NITROMETRIC estimation of nitrogen in nitrocelluloses and, to a lesser extent, in inorganic nitrates, always gives low results, and the conclusion previously reached (J., 1914, 628) that with 96% sulphuric acid the various errors compensate one another is now shown to be incorrect. The interval of time which is allowed to elapse between the introduction of the nitrate and sulphuric acid into the nitrometer and the shaking has a great influence on the results, particularly with the nitrocelluloses, the diminution in volume of crude nitric oxide obtained being the more pronounced the stronger the sulphuric acid and the longer the interval. As the result of analyses of the crude gas evolved under varying conditions and of the residual sulphuric acid, whereby the necessary correction was calculated, the best results were found to be obtained by using 15 c.c. of 92.5—94.0% sulphuric acid and by allowing $\frac{1}{2}$ to $\frac{3}{4}$ hour to elapse between the introduction of the nitrocellulose and acid into the nitrometer and the shaking. In this case the error is about -0.7% of the total nitrogen found.

—G. F. M.

PATENTS.

Explosive mixture. R. L. Hill, Tamaqua, Pa., Assignor to Atlas Powder Co., Wilmington, Del. U.S. Pat. 1,334,303, 23.3.20. Appl., 30.8.18.

AN explosive mixture consists of ammonium perchlorate, nitro-starch, and a metallic compound capable of combining with chlorine.—W. J. W.

Solvent from smokeless powder; Process for recovering —. E. du Pont, Wilmington, Del. U.S. Pat. 1,334,360, 23.3.20. Appl., 13.6.19.

IN recovering from smokeless powders a mixed solvent, the constituents of which have different boiling points, the solvent is slowly vaporised, a portion of the vapour is cooled to condense only the vapour of higher boiling point, the uncondensed vapour is returned to and passed through the material, and another portion of the vapour is cooled and condensed.—L. A. C.

Explosive compounds. Atlas Powder Co., Wilmington, Del., Assignees of R. L. Hill and A. J. Strane, Tamaqua, Pa., U.S.A. Eng. Pat. 134,523, 1.9.19. (Appl. 21,438/19.) Int. Conv., 1.11.18.

Displacement of liquids in nitrocellulose. Ger. Pats. 305,512 and 307,701-2. See XI.

XXIII.—ANALYSIS.

Finger-prints; Detection of — on documents. C. A. Mitchell. Analyst, 1920, 45, 122—129.

For the mechanical development of finger-prints upon paper good results may be obtained by the use of various dry powders, such as graphite, red lead, cadmium iodide, methylene blue, etc. Forgeot's ink method is based upon the fact that there is normally a slight secretion of oil on the fingers, which repels the liquid from the parts of the paper on which the papillary ridges have rested. Variable results obtained by different workers are attributable to variations in the composition of the ink. A suitable ink for the purpose is obtained by dissolving pyrogallol in 1% osmium tetroxide solution, which behaves like iron salts in forming an ink with substances containing three hydroxyl groups in juxtaposition. The reaction also affords a sensitive test for osmium tetroxide. The most sensitive vapour-reagent for finger-prints is iodine, but mercuric iodide vapour gives more stable colorations. Osmium tetroxide vapour gives permanent colorations with recent finger-prints, but is less trustworthy than iodine vapour. Conversely, the reaction may be used for detecting osmium tetroxide, a slightly greasy finger-print being exposed to the vapour.—C. A. M.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Andrew, Miller, Trevelyan, and Armstrong, Whitworth and Co. Furnaces burning powdered fuel. 12,471. May 5.

Blagden, and Howards and Sons. Manufacture of catalysts for dehydrogenation, and application of such catalysts. 12,513. May 5.

De Laval Separator Co. Centrifugal separator. 12,631. May 6. (U.S., 31.8.17.)

Eustis. Recovery of gases. 12,368. May 4.

Fairweather (Lysekils Mekaniska Verkstads Aktiebolag). 11,661. See XIX.

Gröndal. Apparatus for lixiviating granular or pulverulent material. 11,927. Apr. 29. (Sweden, 29.4.19.)

Hamer. Producing high temperatures in heat-energy carrying fluids. 11,531. Apr. 26.

Harris. Drying apparatus. 12,009. Apr. 30.

Leigh and Little. 11,785. See II.

Merry. Evaporation of liquids. 12,454. May 5.

Merry. Utilisation of natural thermal energy. 12,601. May 6.

Nauerz. Condensing gases and gaseous acids. 11,676. Apr. 27. (France, 30.4.19.)

Sutton. Apparatus for effecting reactions between gases. 12,249. May 3.

Thornycroft. Apparatus for extraction of juice from vegetable substances. 11,822. Apr. 28.

Union Espagnole de Fabriques d'Engrais, de Produits Chimiques, et de Superphosphates. Roller crushing machines. 11,489. Apr. 26. (France, 9.3.14.)

Wade (Norton Co.). Grinding machines. 12,255. May 3.

Walpole. Extraction apparatus. 11,571. Apr. 26.

Weyers. Downdraught kilns, ovens, etc. 11,518. Apr. 26. (Holland, 2.5.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

2004 (1919). Ablett. Method of subjecting material to chemical treatment and grinding or/and mixing and apparatus therefor, also ball mill and combined grinding or/and mixing and vacuum drying apparatus. (142,176.) May 12.

3156 (1919). Arter. Grinding machines. (141,831.) May 5.

4959 (1919). Van Norman. Grinding machines. (141,851.) May 5.

5975 (1919). Laverack. Means or apparatus employed for drying excreta, mucilaginous, and other solid matters containing a large proportion of water. (141,861.) May 5.

7250 (1919). Davis. Apparatus for drying or cooling coal, limestone, and other substances or materials in granular form. (141,873.) May 5.

13,751 (1919). Durrans, and Boake, Roberts, and Co. Still-heads. (112,330.) May 12.

16,015 (1919). Conte. Process of and apparatus for separating solids from liquids. (128,941.) May 12.

25,018 (1919). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. Effecting crystallisation from solution. (134,207.) May 12.

25,186 (1919). Gaillet. Combination of pyramidal surfaces for purification of liquids, vapours, and gases. (133,971.) May 12.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Barrett Co. 11,833. *See* XIII.
 Culver. Artificial fuel. 11,546. Apr. 26.
 De Laval Separator Co. Process for cleaning gasoline. 12,629. May 6. (U.S., 23.9.18.)
 Dobson and Pickard. Gas-producers. 12,271. May 4.
 Duckham, and Woodall, Duckham, and Jones. Gasification of coal etc. 11,802. Apr. 28.
 Engelke. Treating hydrocarbon oils. 11,679. Apr. 27.
 Fitzgerald. Utilisation of crude etc. petroleum oils etc. 11,581. Apr. 27.
 Lambert. Recovery of condensable gases or vapours from carbon. 12,709. May 7.
 Leigh and Little. Treatment of dust from gas-cleaning plants. 11,785. Apr. 28.
 Perry. Apparatus for distilling and briquetting carbonaceous material. 12,802. May 8.
 Twynam. Gasification of fuel. 12,741. May 7.
 Wilson. Method of treating and utilising carbonaceous materials with recovery of hydrocarbon oils contained therein. 12,500. May 5.

COMPLETE SPECIFICATIONS ACCEPTED.

- 21,021 (1918). Crush. Gas-producing plant. (141,771.) May 5.
 21,724 (1918). Christopher. Method of and apparatus for the distillation, carbonisation, or gasification of coal, carbonaceous material, oil shales, and the like. (142,163.) May 12.
 2706 (1919). Holt and Walker. Method of manufacturing gas from coal or like carbonaceous material. (141,828.) May 5.
 2825 (1919). Hack and Boughton. Apparatus for washing gas. (142,203.) May 12.
 2905 (1919). Mann. Process relating to the decomposition of hydrocarbons and other substances in the liquid and/or vapour phases. (142,206.) May 12.
 2974 (1919). Hurez. Coke ovens. (123,099.) May 12.
 20,002 (1919). Steinschneider. Distilling-boiler, more especially for the distillation of heavy hydrocarbons of the petroleum, lignite-tar, and coal-tar industry and the like. (142,376.) May 12.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- Brégeat. Process for recovery of naphthalene and/or camphor from gaseous mixtures. 12,753. May 7.
 Drew and Morgan. Production of toluene derivatives. 12,470. May 5.
 Sutton. Manufacture of naphtholates and hydroxynaphthoic acids. 12,140. May 1.

COMPLETE SPECIFICATION ACCEPTED.

- 20,002 (1919). Steinschneider. *See* II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

- Carpmael (Farbenfabr. vorm. F. Bayer and Co.). Manufacture of indigoid vat dyestuffs. 12,526. May 5.
 Carpmael (Farbenfabr. vorm. F. Bayer and Co.). Manufacture of azo dyes. 12,639. May 6.

COMPLETE SPECIFICATION ACCEPTED.

- 524 (1917). Vidal. Preparation of a black colouring-material. (141,759.) May 5.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Beaver and Claremont. Impregnating paper etc. with electrical insulating-compounds etc. 11,658. Apr. 27.
 Briggs, and British Cellulose and Chemical Manufacturing Co. Treatment of fibres and fabrics. 11,886. Apr. 29.
 Bronnert. Manufacture of artificial silk. 12,051 and 12,719. Apr. 30 and May 7.
 Burlin. Process of manufacture of paper etc. pulp from peat. 11,458. Apr. 26.
 Green. Cellulose acetate and nitrate compositions and light esters. 12,605. May 6.
 Summers. Process of retting flax etc. 12,106. May 1.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,688 (1919). Dreyfus. Manufacture of solutions of cellulose acetate and of celluloid-like masses, films, and other products or articles produced therewith. (128,215.) May 5.
 18,129 (1919). Robinson. Production of fibres from flax or the like. (141,982.) May 5.
 19,165 (1919). Duclaux. Process for the purification of nitrocellulose. (130,619.) May 5.
 27,209 (1919). Stulemeyer. Method and means for manufacture of artificial silk. (142,038.) May 5.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Euster and Olig. Machine for mercerising yarn. 12,382. May 4. (Germany, 10.7.19.)
 Pearce. Holders for dyeing cops etc. 12,298. May 4.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Busico. 12,750. *See* XV.
 Fairweather (Fredrikstad Elektrokemiske Fabriker Aktieselskabet). Process for manufacture of perborates by electrolysis. 12,701. May 7.
 Gibbs. Production of magnesium salts. 11,563. Apr. 26.
 Hauenschield. 11,814. *See* IX.
 Hoseason and Norris. Preparation of chlorine compounds, and methods of employing same. 12,655. May 7.
 Levy and Terrisse. Regenerating hydrochloric acid. 12,751. May 7. (Switz., 15.11.19.)
 Matheson. Manufacture of alum and sulphate of alumina. 12,628. May 6.
 Matheson. Manufacture of sulphuric acid. 12,630. May 6.
 Nauerz. 11,676. *See* I.
 Parrish, and South Metropolitan Gas Co. Manufacture of ammonium sulphate. 12,039. Apr. 30.
 Parrish, and South Metropolitan Gas Co. Manufacture of ammonium sulphides. 12,040. Apr. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

- 1466 (1918). Soc. Industrielle de Produits Chimiques. Process for isolating or purifying alkali chromates. (119,647.) May 5.
 15,514 (1918). Soc. l'Air Liquide (Soc. Anon. pour l'Exploit. des Proc. G. Claude). Apparatus for the synthesis of ammonia at very high pressures. (142,150.) May 12.
 17,650 (1918). Heberlein. Method of and apparatus for electrolysing a solution of a nickel salt. (141,766.) May 5.

17,749 (1918). Maconochie and De Ros. Methods of and apparatus for the oxidation of tin and the production of tin oxide, the improvements, being also applicable for the treatment of zinc and zinc-containing materials for the production of zinc oxide. (142,157.) May 12.

693 (1919). Percival, and Edison Swan Electric Co. Production of argon. (111,783.) May 5.

1313 (1919). Linder and Lessing. Manufacture of sulphate of ammonia. (141,787.) May 5.

1427 (1919). South Metropolitan Gas Co., Evans, and Hollings. Manufacture of ammonium sulphate. (141,798.) May 5.

1428 (1919). South Metropolitan Gas Co., and Weight. Manufacture of sulphate of ammonia. (141,799.) May 5.

1744 (1919). South Metropolitan Gas Co., Parrish, and Vilon. Manufacture of neutral sulphate of ammonia. (141,819.) May 5.

2729 (1919). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. Production of pure concentrated nitric acid and tetroxide of nitrogen. (124,191.) May 5.

6438 (1919). British Thomson-Houston Co. (General Electric Co.). Methods of and apparatus for fractionating air. (141,861.) May 5.

10,150 (1919). British Thomson-Houston Co. (General Electric Co.). Production of fluid halogen compounds of silicon, boron, or titanium. (141,908.) May 5.

11,793 (1919). Langwell. Manufacture of finely-subdivided barium carbonate. (141,925.) May 5.

13,009 (1919). Minton, and United Alkali Co. Apparatus for the manufacture of detached or flake caustic-soda or other matter required to be obtained in a state of division from a fused or molten mass. (141,942.) May 5.

16,359 (1919). Duchemin. *See* XVI.
1997 (1920). Soc. Industrielle de Produits Chimiques. Process for isolating or purifying alkali chromates. (138,111.) May 12.

VIII.—GLASS, CERAMICS.

APPLICATIONS.

Delannay and Dimitri. Process for manufacture of refractory and insulating products. 12,143 and 12,145. May 1. (France, 21.11.16 and 16.7.18.)

Lawley (Cambridge Glass Co.). Manufacture of glass. 12,111. May 5.

Norske Aktieselskab for Elektrokemisk Industri Norsk Industri Hypotekbank. Manufacture of porous material. 12,618. May 6. (Norway, 16.5.19.)

Somerville, and South Metropolitan Gas Co. Glass vessels containing wire to be heated to incandescence. 12,377. May 4.

COMPLETE SPECIFICATIONS ACCEPTED.

20,912 (1918) and 526 (1919). Adair. Drying of china clay, and arrangements connected therewith. (142,161.) May 12.

17,226 (1919). Langwell. Manufacture of glass. (142,365.) May 12.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Bakema. Blast furnaces for manufacture of cement etc. 12,827. May 8.

Hauenschild. Burning or calcining cement, magnesite, etc. 11,814. Apr. 28.

Henggeler and Hottinger. Process for production of hydraulic mortar. 12,316. May 4.

Stewart and Woolcock. Concrete products. 12,337. May 4.

Walton. Method of producing coloured effects on or in plaster of Paris, artificial stone, cements, etc. 12,200. May 3.

COMPLETE SPECIFICATIONS ACCEPTED.

5317 (1919). Sharratt. Brick-kilns. (142,237.) May 12.

18,772 (1919). Roy. Process and apparatus for rendering wood impermeable, and recovering liquids contained therein. (130,981.) May 12.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Amalgamated Zinc (de Bavay's), Ltd. Recovery of lead and silver from sulphide ores and metallurgical products. 11,831 and 12,589. Apr. 28 and May 6. (Australia, 17.5 and 6.5.19.)

Cowper-Coles. Electro-deposition of iron alloys. 12,662. May 7.

Cunningham. Process for coating aluminium etc. with nickel etc. 11,513. Apr. 26.

Electrolytic Zinc Co. Recovery of zinc by electrolysis. 11,934. Apr. 29. (Australia, 24.12.19.)

Emesco, Ltd. 12,456. *See* XI.

Kring and Stalhane. Coating metal objects with another metal. 12,214. May 3.

Walter. Alloys of metals of the ferro-chromium group and silicon or its compounds. 12,386. May 4. (Germany, 7.1.20.)

Walter. Method of producing alloys with metals of the ferro-chromium group and silicon or its compounds. 12,387. May 4. (Germany, 14.1.20.)

Walter. Method of producing alloys with metals of the ferro-chromium group and silicon or its compounds. 12,486. May 5. (Austria, 20.3.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

17,749 (1918). Maconochie and De Ros. *See* VII.

1156 (1919). District Chemical Co., and Hoblyn. Mixtures for carburising steel during the case-hardening process. (141,802.) May 5.

6392 (1919). Gasche. Grading or concentration of ores and the like. (142,246.) May 12.

11,725 (1919). McKechnie, and McKechnie Bros. Method for separating or recovering nickel from cupro-nickel alloys, scrap, and the like. (142,310.) May 12.

11,868 (1919). Perez. Process for decomposing mercury, and obtaining radium and gold, which are contained in the formation of this metal. (126,961.) May 5.

12,372 (1919). Harris. Dezincing of lead. (142,315.) May 12.

14,161 (1919). Jarvis. Manufacture of steel. (141,956.) May 5.

16,849 (1919). Brettell (Snead and Co. Iron Works). Heat treatment of metals, and apparatus therefor. (142,358.) May 12.

25,316 (1919). Harris. Refining of lead. (142,398.) May 12.

29,038 (1919). Belais. Gold alloys. (142,018.) May 5.

29,302 (1919). Dorr Co. Treatment of fine ores. (135,844.) May 5.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Allen. Electrodes for secondary or storage batteries. 12,567. May 6.

British Thomson-Houston Co., and Ralph. Electric furnaces. 12,811. May 5.

British Thomson-Houston Co. (General Electric Co.). Devices for controlling electric discharges through gases and vapours, and methods of operating said devices. 12,225. May 3.

4275 (1919). Selden Co., and Selden. Process of treating cymene. (142,226.) May 12.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Jeffreys. Photography. 12,564. May 6.

COMPLETE SPECIFICATIONS ACCEPTED.

11,417 (1919). Marks (Du Pont de Nemours and Co.). Composition for detonators. (142,303.) May 12.
 19,165 (1919). Duclaux. *See* V.

I.—GENERAL; PLANT; MACHINERY.

Metallic catalysts; Effect of surface oxidation on some — F. F. Rupert. J. Amer. Chem. Soc., 1920, 42, 402—411.

PLATINUM foil which has been used as an anode for the electrolysis of water acquires increased catalytic activity towards detonating gas (electrolytic hydrogen-oxygen mixtures), which is due to surface oxidation, and can be induced by chemical means, as well as by anodic polarisation. A similar effect was found in the case of palladium and gold. In the case of cobalt, a slight increase in activity was detected, but was probably due to an increase in the area of active surface by etching. The catalytic activity of smooth palladium towards the hydrogenation of cottonseed oil is increased by surface oxidation. Palladium is 50 times as active towards detonating gas as platinum, whilst platinum is 2000 times as active as gold, and 200 times as active as cobalt.—E. H. R.

Waste heat and its importance in future heat economy. E. Reutlinger. Z. Dampfkessel u. Maschinen-betrieb, 1919, 42, 377—378, 394—397, 401—404.

Production of low-temperature tar in steam power plants. Wilkens. See IIa.

PATENTS.

Heat treatment of chemical compounds [under pressure]; Apparatus for — and method for operation thereof. F. X. Govers. E.P. 129,962, 22.11.18. (Appl. 19,271/18.) Conv., 18.7.18.

TUBULAR heating apparatus is kept clean internally by means of balls which are fed continuously, one at a time, with the chemical under treatment, and withdrawn after the process is finished. By this means long, continuous tubes with no joints for cleaning purposes may be used. Should a catalyst be necessary for the desired reaction, the balls may be made of the catalyst. A suitable form of ball-feeding apparatus consists of two discs rotating above and below a distance piece, which is rather thicker than the diameter of the balls. Holes are made in each of the discs, but not opposite each other, also in the distance piece, through which one ball at a time can drop. To deliver the material to be heated, it is preferable to have a pump capable of giving a large excess pressure, so that if a ball comes to rest against an obstruction, the obstruction may be removed by the scouring action of the liquid or gas under treatment forced at high velocity between the ball and the wall of the tube.—B. M. V.

Roller [rod] mills. F. E. Marcy, Salt Lake City. E.P. 136,950, 5.2.19. (Appl. 2854/19.)

In a rod mill the discharge end is left open, permitting ready inspection and admission and withdrawal of the grinding rods, and devices are provided for retaining the grinding rods, while allowing free outlet of the ground material.

—B. M. V.

Vacuum filters; Continuous — A. E. Alexander. From United Filters Corp., Brooklyn, U.S.A. E.P. 141,001, 30.12.18. (Appl. 2581/20.)

To allow of withdrawing the filtrate and wash liquors separately, the central shaft supporting the segmental filter leaves of vacuum filters of the rotating leaf type is constructed of a number of tubes (parallel to the axis) communicating with the leaves by means of ports extending through segmental clamps and with the vacuum apparatus by means of a rotating valve.—B. M. V.

Filters; Continuous — A. E. Alexander. From United Filters Corp. E.P. 136,309, 30.12.18.

In a continuous vacuum filter with segmental filter leaves (U.S.P. 1,293,555; J., 1919, 276 A) means are provided for inflating the filter bags at an appropriate stage, and thus bringing them in contact with scrapers to remove the filter cakes.

Filter presses. P. W. Norman, Teddington, and The Aluminium Plant and Vessel Co., Ltd., Wandsworth. E.P. 140,715, 27.10.19. (Appl. 26,358/19.)

In filter-presses of the plate and distance frame type provided with a common longitudinal outlet duct formed by ports in the plates, the passages from the plate surfaces to the outlet duct are more easily cleaned if drilled on the slant, either a separate passage from each face, or one inclined passage extending from a larger transverse hole through the plate; this latter hole, being within the filtering area, may be partly filled by a suitable plug.

—B. M. V.

Filter-table; Rotary — E. L. Oliver, Oakland, Cal. U.S.P. 1,335,695, 30.3.20. Appl., 28.5.18.

A HORIZONTAL rotary pan is divided into a number of compartments, each having a filter bed, and discharge conduits lead from each compartment to a central valve plate. The valve is adjustable, so that suction may be applied to different groups of conduits in succession, and thus to filter beds, which are at different distances from the supply of unfiltered liquid.—W. F. F.

Filtration; Method of and apparatus for — O. J. Salisbury, Assignor to United Filters Corp., Salt Lake City. U.S.P. 1,336,444, 13.4.20. Appl., 29.8.17.

THE filter cake is dried *in situ* before removal from the filtering medium, by heat applied to it in the direction of the passage of the filtrate.—W. F. F.

Filtering machine [for gases]. H. W. Tuttle. U.S.P. 1,336,600, 13.4.20. Appl., 28.9.17.

Gas to be filtered is passed through a number of filtering devices which are agitated simultaneously. The filtering devices are cleaned by passing a reverse current of air through the chamber containing them, while the agitation is continued.

—W. F. F.

Filter. L. Wachenberg, New York. U.S.P. 1,337,170, 13.4.20. Appl., 5.4.19.

A HORIZONTAL filter drum is mounted on hollow trunnions, and liquid is delivered through one of the trunnions to the filtering elements within the drum. An annular conduit, surrounding the liquid conduit in the same trunnion, is connected to pipes supplying hot water and compressed air for cleaning the filtering elements. The cleaning fluid passes through the filtering elements in the reverse direction, and is also delivered simultaneously against the outer sides of the filtering elements. The drum is rotated during the cleaning operation.

—W. F. F.

Washing of granular filter material; Regulating the air supply in the intermittent — K. Morawe, Berlin-Friedenau. G.P. 315,270, 5.1.17. Addition to 311,593.

In the process originally described (J., 1919, 522 A) it is advantageous to be able to set the air valves automatically, as the duration of a wash is too short to admit of the regulation of an ordinary tap. Suitable regulating devices are described.

—H. J. H.

Rotary kilns, and method and means of heating same [by fluid or solid fuel]. H. Fenton, Batley, and A. W. H. Vivian, London. E.P. 140,514, 21.12.18. (Appl. 21,470/18.)

A COMBUSTION chamber, preferably of circular cross-section corresponding with the interior of the kiln, is built at the lower end of a rotary kiln, and a burner for oil or gas fuel extends into this chamber approximately in alignment with the axis of the kiln. In addition, passages on either side of the combustion chamber extend upwards from a pair of hearths for solid fuel.—B. M. V.

Furnaces for burning low grade fuel. F. Cotton, Sydney, N.S.W. E.P. 140,972, 12.9.19. (Appl. 22,444/19.)

THE fuel rests directly on the level front portion of the hearth of the furnace, the back portion of the hearth sloping steeply upwards to the fire-bridge. A deep bed of fuel is maintained, and air is supplied by induction by jets of superheated steam through conduits formed directly through the front of the furnace, also from the front along the thickness of the side walls, turning into the furnace at suitable places. The furnace may be divided into two or more compartments by feather walls which do not extend right up to the roof, and each of which carries outlets for the air blast on both of its faces.—B. M. V.

Tubular heating appliances of vacuum pans and other liquid heating apparatus. Fawcett, Preston and Co., Ltd. From H. W. Taylor, Mauritius. E.P. 140,635, 3.5.19. (Appl. 11,042/19.)

THE heating tubes in the bottom of the pan or vessel are bent into semi-circles and fastened into headers, which are provided with baffles to cause the steam or other heating medium to pass half round a circle and then back again several times. Small openings may be left for the direct passage of condensed water from the inlet at the top to the outlet at the bottom division of the header. Means of suspending the tubes are described.—B. M. V.

Cooling-towers or structures for cooling water and other liquids. F. E. Gill, Shipley, and The Davenport Engineering Co., Ltd., Bradford. E.P. 140,898, 24.3.19. (Appl. 7264/19.)

A WATER distributing apparatus for the tops of cooling-towers, that will not silt up, may consist of pipes or closed troughs with outlets in the upper parts of their circumference carrying rotary spraying nozzles, the water being supplied under pressure.—B. M. V.

Cooling gases; Apparatus for —. J. A. Reavell, and Kestner Evaporator and Engineering Co., Ltd. E.P. 141,097, 4.12.18. (Appl. 20,040/18.)

THE cooling liquid is passed through vertical U-tubes connected in groups to headers. A baffle is provided between the vertical limbs of the U, and the gas to be cooled is admitted around the top of one and exhausted at the top of the other limb, passing down and up along the tubes. Dust separated from the gas drops off the tubes to a chamber below the bend of the U, and its removal may be aided by rapping the tubes.—B. M. V.

Volatile solvents; Recovery of —. D. V. Plumbridge, Rugby. E.P. 141,210, 14.5.19. (Appl. 12,103/19.)

For the recovery of volatile solvents from a material such as fabric that has been treated with rubber solution, the drying apparatus is covered by a closely fitting hood, and air is circulated within the hood by one fan and the saturated air withdrawn to a condenser by the same or another fan. A cut-off valve is provided, which may be interconnected

with the means of starting and stopping the machine. The gases on the way to the condenser may be compressed, and the condenser may be provided with baffles to remove fog.—B. M. V.

Drying kiln; Vertical —. J. C. Brian, Belfast. E.P. 141,468, 1.3.19. (Appl. 5121/19.)

GRAIN or like material from a hopper is fed by a distributing cone on to a series of louvres so that the falling material forms the walls of a chamber, from which air is exhausted by a fan and delivered to a heating furnace either above or below the firebars. The air after reheating is returned to the outer chamber of the dryer which surrounds the falling material.—B. M. V.

Drying apparatus. F. V. Burman, Marine City. U.S.P. 1,336,422, 13.4.20. Appl., 25.6.19.

MATERIAL is fed into a horizontal rotating drum by a shoot at one end, and the heating medium is admitted into the drum at the same end. A heat-protecting wall is arranged behind the shoot.—W. F. F.

Crystallisation; Treatment of liquids to effect therefrom while the liquid is kept in motion. B. Bakke, Assignor to Norsk Hydro-Elektrisk Kvaestofaktieselskab, Christiania. U.S.P. 1,329,158, 27.1.20. Appl., 29.9.19.

THE solution is contained in a revolving tube, the top of which is kept at a relatively high temperature while the lower part is subjected to cooling.—A. J. H.

Vapours and gases; Method and apparatus for separating —. W. A. Patrick, B. F. Lovelace, and E. B. Miller, Baltimore. U.S.P. 1,335,348, 30.3.20. Appl., 28.12.18.

A MIXTURE of gases or vapours is passed into a porous material having pores similar in size to those of hydrated silica gel, and the gas or vapour retained in the material is afterwards liberated.—W. F. F.

Liquids; Apparatus for treating — with gases. W. Sieck, jun., and S. Drucker, Chicago. U.S.P. 1,335,398, 30.3.20. Appl., 16.6.19.

A CYLINDER with open ends is fixed, with its axis vertical, coaxially within a cylindrical container for the liquid. The gas is introduced into the liquid through a perforated pipe near the lower end of the open cylinder, and a helical blade is mounted on a rotating vertical shaft passing coaxially through the open cylinder so that a flow of liquid is produced in the cylinder in counter current to the flow of gas.—W. F. F.

Gas-vapour mixtures; Method of treating [liquefying] —. W. E. Lummas, Lynn, Mass. U.S.P. 1,336,360, 6.4.20. Appl., 5.5.16.

THE mixture of gas and vapour is passed into a water-cooled condenser, where part of the vapour is liquefied, and the liquid then passes through a water-cooled coil in a separate vessel. The cooled liquid and the uncondensed gas and vapour from the condenser are then passed in counter current through a column scrubber to recover any residual liquefiable vapour.—W. F. F.

Still and still-setting. H. Henderson, Port Arthur, Assignor to Gulf Refining Co., Pittsburgh. U.S.P. 1,335,438, 30.3.20. Appl., 14.3.16.

A STILL is supported on a framework which exposes the lower part to view, and is heated externally. Heat-insulating material is applied only on the exterior upper portion and the interior of the lower portion of the still, and an internal heating device is also provided.—W. F. F.

Surface condenser. S. M. Lillio, Philadelphia. U.S.P. 1,335,692, 30.3.20. Appl., 18.4.19.

A TUBULAR surface condenser is provided with additional tube-plates close to the main tube-plates and adjacent to the condensing space; all the tubes pass through holes in the additional tube-plates. Means are provided for withdrawing liquid and air from the narrow spaces between the two pairs of tube-plates.—W. F. F.

[Electrically] **classifying finely-divided material.** W. A. Schmidt, Assignor to International Precipitation Co., Los Angeles. U.S.P. 1,335,758, 6.4.20. Appl., 28.8.16.

PARTICLES of different size, suspended in a gas, are separated by passing the gas successively, at uniform velocity, through a series of electric fields of similar intensity and uniform cross-sectional area, so as to produce a succession of electrical actions on the gas. Particles, progressively smaller in size, are precipitated successively.—B. N.

Electrodes for use in electrical precipitation apparatus. Siemens-Schuckertwerke G.m.b.H. G.P. 316,703, 28.6.18.

GASES are passed through a chamber containing precipitation electrodes constructed of parallel sheets of net or gauze having a corrugated or zig-zag section, and high-potential electrodes arranged in the cavities formed by the corrugations of the sheets.—L. A. C.

Gases; Rotary apparatus for removing dust from —. Siemens-Schuckertwerke G.m.b.H. G.P. 316,901, 9.5.18.

GAS enters a vertical cylindrical chamber through an opening in the side, and is deflected by a plate which causes deposition of the coarser particles of dust; the gas is then drawn upwards through a rotating fan fitted with vanes of wire gauze, and passes out of the top of the chamber. The dust settles to the bottom of the chamber and is removed.—L. A. C.

Catalyst furnaces. H. C. Greenwood and W. R. Tate, London. U.S.P. 1,335,891, 6.4.20. Appl., 26.3.19.

A VERTICAL, cylindrical catalyst space is surrounded by a heat interchanger consisting of one or more annular partitions of heat-insulating material. The partitions are made of a cross section which tapers gradually from one end to the other to conform to the varying temperature gradient.—W. F. F.

Contact masses; Preparation of — for catalytic treatment of gases. Nitrogen-Ges.m.b.H. G.P. 312,726, 16.3.12.

THE catalyst is intimately incorporated with hydraulic cement, and the mass allowed to set without pressure; or the cement may be gauged, allowed to set, impregnated with a solution of the catalyst, and then dried. A contact mass composed of 85% cement, 10% copper oxide, and 5% alumina is effective in the oxidation of carbon monoxide at 210°–220° C. and most efficient at 360° C., whereas for contact masses with a clay or brick basis the corresponding temperatures are 650°–700° C. and 780°–825° C.—A. J. H.

Separating machine; Centrifugal —. R. E. Lapham, San Francisco. U.S.P. 1,336,968, 13.4.20. Appl., 8.6.16.

A ROTATING separating bowl is provided with a reservoir containing a separating medium which is caused to move over the inner surface of the bowl by its rotation. Pulp is supplied to the bowl, and is separated into its constituents according to their density. Separate outlets are provided for the pulp tailings and the separating medium, and they are

directed towards their respective outlets, after the separating operation, by a force acting in opposition to the outflow of the separating medium.—W. F. F.

Sedimentation apparatus. C. L. Peek, New York, Assignor to The Dorr Co. U.S.P. (A) 1,337,094 and (n) 1,337,095, 13.4.20. Appl., 5.10.18.

SETTLED sludge is removed from apparatus, such as a Dorr thickener, upwards through a vertical sleeve surrounding the central driving shaft. The material is continuously withdrawn from the sleeve or sludge well by means such as an air lift so that a hydrostatic head is maintained between the main part of the tank and the sludge well, and communication is effected between the two by means of (A) the open bottom of the sludge well or (n) a conduit extending from the closed bottom of the sludge well to near the bottom of the tank.—B. M. V.

Refrigerating; Process of and apparatus for — F. W. Wolf, Assignor to The Isko Co., Chicago. U.S.P. 1,337,175, 13.4.20. Appl., 23.12.13.

THE apparatus includes in a closed circuit a compressor in which sulphur dioxide is compressed, an atmospherically cooled condenser for the compressed gas, and a chamber into which the condensed liquid is expanded.—W. F. F.

Tower for absorbing or concentrating gases. Chem. Fabr. Griesheim-Elektron. G.P. 305,122, 29.9.17.

A TOWER for absorbing gases, e.g., acids, in which the gas enters at the lower and passes out at the upper end and is washed by a counter-current of liquid, is constructed with double walls, the annular intermediate space being filled with packing, such as gravel, quartzite, etc., supported by a number of rings sloping towards the inner wall. In the annular chamber, which protects the outer walls of the tower and prevents loss of heat, the gases escaping from the inner chamber are again scrubbed by the liquid.—L. A. C.

Liquids; Chamber for drying —. L. Galland, Berlin-Wilmersdorf. G.P. 305,511, 21.10.17.

through D. The moist air escapes through E.—L. A. C.

Dehydration of mineral, vegetable, and animal products by means of electro-osmosis; Apparatus for —. Elektro-Osmose A.-G. G.P. 310,681, 4.7.17.

THE material is subjected to electro-osmotic treatment between a drum and an endless band, which serve as the respective electrodes. The drum and band rotate in the same direction, and the distance between the two steadily diminishes in the direction of motion. The band is pressed against the material under treatment by springs, and the distance between it and the drum is adjustable. The band may be made of brass webbing or of cloth overlaid with a deposit of metal. The band is cleaned by passage through water in an insulated trough.

—J. S. G. T.

Drying sludges of which the solid components are partly impermeable to water; Process for —. T. Steen, Charlottenburg. G.P. 314,595, 23.2.17. Addition to 314,043.

In the method previously described (J., 1919, 885 A) the impermeable material which penetrates into the permeable layer is removed from time to time by cuts of greater depth than usual. The filter bed is thus kept in working condition, without complete renewal, for a longer period.—L. A. C.

Sludge or the like; Apparatus for removing water from —. E. Techen, Leipzig. G.P. 315,312, 10.10.15. Addition to 278,258.

In the apparatus described in the chief patent (J., 1915, 213) the rotating drum is enclosed in a closed outer casing. Suction is applied as before through a contrivance within the drum, and filtration is assisted by application of pressure, e.g., by means of compressed air, to the annular space between the drum and the outer casing. Scrapers adjustable from the exterior are provided to remove the cake from the U-shaped trough, and the material is then forced by pressure through doors in the lower portion of the casing, which open and close automatically. By admitting water, steam, and hot air into the annular space the cake can be washed and dried before removal from the apparatus.—L. A. C.

Sludge; Apparatus for drying —. T. Steen, Charlottenburg. G.P. 315,553, 25.3.17. Addition to 314,043.

An apparatus for drying sludge by the process described in Ger. Pat. 314,043 (J., 1919, 885 A) consists of rotating filter beds, *a*, supported by a shaft,

b. The suction pipes, *n*, pass to a common holder, *m*, and suction is applied through *t*, *k*, and *i*; the holder, *m*, is connected to a water trap, *p*. The dried material from the filter bed falls on to an endless band, *r*, which conveys it away to be worked up for further use.—L. A. C.

Washing or chemical or mechanical treatment of materials. T. Steen, Charlottenburg. G.P. 315,780, 10.11.17.

The material is passed through a number of containers in which it is washed or treated with water or other liquid, the mixture passing from one container to the next through air-lift tubes. Overflows for liquid are provided between the separate containers, and these increase in cross-section and are arranged at progressively lower levels from the first onwards in the direction of motion of the liquid, to allow for the extra liquid introduced at different places in the series.—L. A. C.

Liquids; Method for agitating — by means of a magnetic field. G. W. Meyer, Jitschin. G.P. 316,499, 27.2.18.

A WHIRLING motion is imparted to liquids contained in an annular vessel by means of a rotating mag-

netic field set up between a primary inducer and a stationary or rotating body constructed of sheets of iron. The walls of the vessel are constructed of a material which does not interfere with the direction of the lines of magnetic force.—L. A. C.

Gaseous components; Preparation of solid chemical compounds [e.g., ammonium carbonate] from —. Badische Anilin und Soda Fabrik. G.P. 318,236, 9.7.15.

THE gases are led into chambers provided with a cooled rotating arrangement, and the solid substance produced is continuously removed by means of scrapers. To prevent separation of solid matter on the walls of the chambers, these may be lagged or, if necessary, heated. As an example, the preparation of ammonium carbonate and carbamate from ammonia, carbon dioxide, and steam is cited.—G. F. M.

Roller mill. F. E. Marcy. U.S.P. (A) 1,309,210, (b) 1,309,211, and (c) 1,309,212, 8.7.19. Appl., (A) 14.8.18, (b) 18.1.17, and (c) 26.9.17. (b) and (c) renewed 19.10.18.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Peat; Determination of grade of —. G. Keppeler. Mitt. Ver. Förder. Moorkultur im Deuts. Reiche, 1920, [1]. Chem. Zentr., 1920, 91, II., 548.

THE degree of conversion to peat of mosses can be determined by decomposing the material by 72% sulphuric acid. The polysaccharides pass into solution, and the sugars can be estimated by titration with Fehling's solution. The dextrose estimated in this way, and calculated on the water- and ash-free peat, is termed the "total reduction." The maximum possible value is 68%, so that if the "total reduction" for any peat be *g*, then $100 - g \times 100 \div 68$ is a measure of the degree of conversion of the original vegetable matter into peat. This value is called the "degree of decomposition." The degree of conversion to peat may also be estimated from the residue after treatment with 72% sulphuric acid. From this residue (referred to 100 parts of organic matter) the ash and also the residuum left in the acid treatment of sphagnum moss (11%) are deducted in order to obtain the "degree of conversion." The newer moss peats generally show a low "degree of conversion," scarcely 30%, whilst the older ones give a much higher value, up to 50%.—A. G.

Tar and other by-products of coal distillation; Production of low-temperature — in steam-power plants. K. Wilkens. Mitt. Verein Elektrizitätswerke, 1919, 18, [241]. Chem. Zentr., 1920, 91, II., 384—385.

THE surplus heat of the steam boilers is utilised for the low-temperature distillation of coal. Between the boiler and the economiser a large number of retorts are built into which the coal is fed, and through which it is transported by screw conveyors, the blades of which are hollow and connected to a suction apparatus. After passing through a condenser the gas is led to a small gas-holder and is burned under the front end of the retorts. The coke is used in the boiler furnace.—G. F. M.

Combustion products or producer gas; Determination of the quantity of — from the analysis and from the calorific value of the coal. F. Cästek. Stahl u. Eisen, 1919, 39, 7—12.

THE author has elaborated a method of calculating the quantity of combustion products or water- or producer-gas in a mixture. By means of thermochemical equations for the complete combustion of pure carbon-hydrogen mixtures, the quantity of heat developed per cub. m. of burnt gases is expressed as a function of their carbon dioxide and oxygen content, and from this the amount of gas and its moisture content are calculated. Neglecting the sulphur and nitrogen present in coal, the pure coal substance can be represented as a carbon-hydrogen mixture, and the process is then applicable to coal. In the case of incomplete combustion (i.e., producer- or water-gas) the quantity of gas is calculated by considering that by complete combustion of the gases from 1 kg. of coal, the same amount of gaseous combustion product must be formed as if 1 kg. of coal were completely burnt direct, and the unburnt carbon in the ash, slag, coal dust, tar, and soot allowed for.—A. R. P.

Hydrocarbons; Catalytic oxidation of —. H. H. Franck. Chem.-Zeit., 1920, 44, 309—310.

By cracking aliphatic hydrocarbons in the presence of oxygen and a suitable catalyst carboxylic acids and other oxidation products are formed. Compounds of lead, manganese, mercury, vanadium, and chromium give good results as catalysts; alkalis and alkaline earths may also be used. For example, the oxidation of 0.5 kg. of hard paraffin wax in presence of 0.5—5% of a lead catalyst in an autoclave yielded, after 2 to 4 hours at 150° C., 460 g. of fatty acids. The mixed esters of these fatty acids yielded 18.75% of volatile (acetic to caproic) and 78.1% insoluble non-volatile acids (myristic to arachidic acids). A dark expressed residue of paraffin wax yielded 65% of fatty acids, the contents of the autoclave being bleached to pale yellow in the process. This product contained 40.7% of insoluble fatty acids in which there were only traces of stearic and arachidic acids. A sample of the mixed fatty acids esterified with glycol in the presence of 3% of sulphuric acid was converted into a solid fat with the odour of coconut oil. When refined this product was pale yellow and had the characters of a good edible fat.—C. A. M.

Spent oxide. See VII.

Heating steel furnaces with producer-gas and coke-oven gas. Schneider. See X.

PATENTS.

Fuel; Apparatus for treating —. W. L. McLaughlin, Decatur. U.S.P. 1,336,364, 6.4.20. Appl., 25.9.18.

COAL is crushed to pea size and dried by showering it through a hot gas zone, after which it is ground to an impalpable powder.—A. G.

Coke ovens and the like. Soc. de Fours à Coke et d'Entreprises Indus. E.P. 129,994, 16.7.19. (Appl. 17,805/19.) Conv., 16.7.18.

IN coke ovens having vertical flues in the walls and regenerators under the oven chambers the vertical flues are symmetrically divided in each heating wall into four groups, each pair being separated from the others by a transverse partition. The air in each of the two groups flows in an opposite direction at any given time, whilst short circuits and stagnant zones in the passages are avoided by dividing the regenerator under the oven chamber longitudinally into four sections, each communicating at the top with only one group of vertical flues, and being completely cut off from the other section.—A. G.

Peat; Carbonising oven for —. R. Schröter. G.P. 316,213, 30.3.16.

A HORIZONTAL carbonising chamber, heated from below, communicates with an adjacent shaft which extends vertically downwards, and in which the carbonised peat is saturated with tar and gaseous products carried by the gases passing down the shaft, so that little besides water vapour escapes into the chimney.—J. H. L.

Gas or gases; Manufacture of —. C. F. Broadhead, Brisbane. E.P. 122 179, 2.1.19. (Appl. 55/19.) Conv., 7.1.18.

A VERTICAL retort is superimposed on a water-gas generator, and coal is fed into the former by a gas-tight valve. Air and steam are blown alternately into the generator. During the air blow the gas valve is closed and the products of combustion pass through ports into an annular space surrounding the retort, the heat generated being transmitted through checker brickwork therein to the retort, and the waste gases passing through a snift valve to the atmosphere. During the steam blow the water-gas generated passes up through the vertical retort, and the heat of the water-gas, together with that transferred to the retort during the air blow, causes the coal to be subjected to low-temperature carbonisation.—A. G.

Water-gas; Production of — from coal carbonised in retorts. A. Peust, Berlin. G.P. 317,825, 9.2.19.

WHEN the evolution of gas from the coal is nearly completed, and whilst the coal is still incandescent, it is covered with a small charge of moistened, fine lignite. The temperature rises, and water-gas is produced without any external blast. The lignite is very soon gasified and carbonised.—J. H. L.

Illuminating gas and tar; Manufacture of —. H. Geyer, Marktredwitz. G.P. 317,977, 12.10.17.

COMMUNUTED coal is distilled in a rotary horizontal retort containing grinding bodies, e.g., balls of refractory material, and is subjected to the action of hot gases, poor in nitrogen. In this way local overheating is avoided.—A. J. H.

Purifiers employed in gas works. R. and J. Dempster, Ltd., and G. F. H. Beard, Manchester. E.P. 141,572, 30.6.19. (Appl. 16,363/19.)

IN gas purifiers employing conduits for directing the gas through the boxes (the conduits having walls forming part of those of the purifier), the valves are in open communication with the interior of the boxes and are situated within the boxes, adjacent to the conduits. (Cf. E.P. 844 of 1915; J., 1915, 897.)—A. G.

Waste liquor; Disposal of — in the recovery of ammonia from the gases produced in dry distillation etc. Phoenix A.-G. für Bergbau u. Hüttenbetrieb. G.P. 307,652, 19.4.14.

THE condensed liquor, after being freed from volatile ammonia, is concentrated in a tower through which a current of air is passed; part of the concentrated liquor is removed and the remainder is passed to the condensers to cool the hot crude gases, and is then returned to the concentrating tower. By this means the use of lime for recovering ammonia from the waste liquor and the use of clean water for cooling are avoided.—A. B. S.

Hydrocarbons; Rectification of —. De Bataafse Petroleum-Maatschappij, and J. H. C. de Brey, The Hague. E.P. 123,719, 7.11.18. (Appl. 18,270/18.) Conv., 1.3.18. Addition to 123,522 (J., 1920, 7A.)

MIXTURES of hydrocarbons are rectified under pressure (below 20 atm.), and the limits of temperature

may be selected so as to cause the elimination of worthless fractions from the liquid component and the removal of the last traces of valuable fractions from the gaseous component. For example, for compressor gasoline under 90 lb. pressure the maximum temperature may be 80° C. and the minimum -5° C. After this preliminary treatment the two components may be rectified.—A. E. D.

Liquid fuels; Production of —. H. Wade. From C. J. M. M. le Petit. E.P. 141,091. (Appls. 18,039, 4.11.18, and 19,134, 21.11.18.)

A MIXTURE of a formyl ester with one or more aliphatic amines is claimed for improving alcohol as a volatile fuel; e.g., such fuel may contain alcohol 65%, ether 34%, mono- or di-ethylamine 0.5%, and ethyl formate 0.5% by weight.—A. E. D.

Desulphurising sulphur-bearing hydrocarbons. Hall Motor Fuel, Ltd., and T. A. McCrea, London. E.P. 141,272, 8.9.19. (Appl. 22,094/19.)

THE vapour of the hydrocarbon is brought into contact with bauxite, clay, or the like at 150°–300° C. —A. E. D.

Lubricating composition; Process of making —. J. A. De Cew, Montreal. U.S.P. 1,336,207, 6.4.20. Appl., 9.10.17.

STABLE aqueous emulsions are prepared from mixtures of oils soluble and insoluble in water, containing a minimum of the former, by forcing the mixtures under pressure, in a fine stream, into hot water, and then forcing the resulting solution under pressure into cold water.—C. A. M.

Lubricating oil; Substitute for —. Tetralin G.m.b.H., Berlin. G.P. 309,178, 20.11.17.

THE lubricants claimed are obtained by polymerisation of hydrogenised naphthalene or naphthalene derivatives, or by combination of these with other organic substances. For example, tetrahydro-naphthalene condenses with benzyl chloride, chlorinated xylene, benzaldehyde, or trioxymethylene on heating or by means of condensing agents; the products are viscous oils of high boiling points. —J. H. L.

Lubricating and cooling agents soluble in water. Chem. Fabr. Flörsheim Dr. H. Noerdlinger. G.P. 316,720, 25.1.17.

AQUEOUS solutions of alkali compounds of the acid products formed by oxidation of wood tar (e.g., from beech, birch, or pine wood) are claimed. They may be added to other known lubricating and cooling agents, and are especially suitable for addition to the water in hydraulic plants, since besides their lubricating and cooling properties they act as disinfectants and tend to prevent rusting.—J. H. L.

Mineral oils; Apparatus for refining —. H. W. Jones, Assignor to The Kansas City Gasoline Co. U.S.P. 1,336,357, 6.4.20. Appl., 7.10.16.

A STILL or retort is composed of a number of vertical tubes close together, connected alternately at the top and bottom by short horizontal tubes so as to form a sinuous path for the circulation of oil. The vertical tubes project slightly beyond the connecting tubes at the top and bottom, the projecting ends being closed, those at the bottom by removable caps to retain deposits and heavy constituents out of the path of the circulating oil.—W. F. F.

Hydrocarbon oils and water; Apparatus for decomposing —. H. C. Wade, Assignor to Wadoll Corp., New York. U.S.P. 1,336,450, 13.4.20. Appl., 11.1.16.

OIL and water, suitably preheated, are heated in a spiral coil which contains "attenuated metal" at the outlet end of the coil.—A. E. D.

Liquid hydrocarbons; Process of converting —. W. C. McComb, Assignor to W. I. Patterson, New York. U.S.P. 1,337,144, 13.4.20. Appl., 15.10.18.

STEAM and the preheated oil are passed through a sinuous passageway of gradually increasing downward pitch towards a source of heat.—A. E. D.

Viscous oils; Process for the preparation of —. K. Börner. G.P. 318,034, 6.11.17.

HOT mineral oils are treated with an amount of chlorine sufficient to chlorinate any desired proportion of the oil, with or without the presence of a solvent; the product is heated above 200° C., air being drawn through at the same time.—B. V. S.

Feeding [powdered] fuel to combustion chambers; Means for —. V. Z. Caracristi, Assignor to Locomotive Pulverized Fuel Co., New York. U.S.P. 1,336,125, 6.4.20. Appl., 27.1.15.

Benzene hydrocarbons from coal-gas; Recovery of —. G. E. Darier. U.S.P. 1,336,893, 13.4.20. Appl., 10.7.16.

Destructive distillation of wood, woody fibre, and similar carbonaceous substances. P. Poore, London. E.P. 141,417, 11.1.19. (Appl. 812/19.)

THE material is carbonised in a horizontal, rotary retort, mounted on a cradle in order to be easily

removed from the furnace for the removal of the residue and for recharging. A central vapour outlet pipe extends the length of the retort, and superheated steam is admitted through longitudinal pipes, adjacent to the walls of the retort.—A. G.

Destructive distillation; Process of —. O. F. Stafford, Eugene, U.S.A. E.P. 141,505, 14.4.19. (Appl. 9491/19.) Addition to 119,040.

Is addition to wood, other cellulosic or ligneous material, e.g. cottonseed hulls, rice hulls, peat, nut shells, fruit pips, straw, vegetable fibres, bagasse, moss, or the like may be carbonised (preferably in a finely divided state) by the process described in the main patent (J., 1919, 215A).—A. G.

Gas-mantle. L. Glaser. U.S.P. 1,335,831, 6.4.20. Appl., 11.10.17.

As automatic igniter consisting of pellets and bands composed of equal parts of platinum black and a silicious material is fused on to the body of an incandescence gas-mantle.—L. A. C.

III.—TAR AND TAR PRODUCTS.

Tar; Effect of superheating on the composition of —. M. Dolch. Montan. Rundsch., 1920, 12, 56–57, 78–79. Chem. Zentr., 1920, 91, 11., 545.

The properties of low-temperature tar produced from Kakani coal are compared with those of the same tar superheated by passing the tar vapours over glowing coke. The yield of tar diminished from 10.8% to 6.2%, the sp. gr. rose from 0.800 to 1.0374, and the free carbon content increased from 1.02% to 4.06%. The percentage of asphaltic matter rose from 31% to 57%, whereas the phenolic compounds decreased in quantity. The paraffins in the low-temperature tar amounted to over 6%, but there was practically no paraffin in the superheated tar. The yield of lubricating oils from the superheated tar amounted to 12%, as compared with 24% from the low-temperature tar, but the "neutral tar oils" increased in quantity from 15% to 24%. The asphaltic constituents of the heated tar were practically all liquid, and commenced to decompose at 348° C., whilst those from the low-temperature tar decomposed at 260°–270° C.—A. G.

Lignite; Uses of low-temperature tar oils from —. Harries. Verh. Vereins Förd. Gewerbell., 1920, 33–39. Chem. Zentr., 1920, 91, 11., 570.

HIGH-TEMPERATURE tars from lignite yield on extraction with liquid sulphur dioxide a highly-unsaturated extract, probably containing cyclic compounds, and a refined oil also containing unsaturated compounds. By ozonisation these products are converted into high-molecular fatty acids suitable for use in soap manufacture. Low-temperature tar yields similar products in the following proportions:—100 parts of lignite give 3 of tar, which can be separated into 1.4 of extract and 1.6 of a mixture of oil and paraffin. After removal of the paraffin, the expressed oil (0.64) yields 0.12 of crude fatty acids on ozonisation. (Cf. J., 1917, 539; 1919, 318 A).—L. A. C.

Coal-tar naphtha distillation test; Electric heater for the —. J. B. Hill and R. B. Chillas. J. Ind. Eng. Chem., 1920, 12, 280–281.

As iron pot is filled with solder to within a short distance of the top; two heating units are fitted at the bottom of the pot and are controlled by a double switch. One unit will heat the solder to 240°–280° C., whilst the two units together will maintain it at 345°–380° C. A ring of asbestos is floated on the surface of the solder, and on this is placed the distillation flask, the heat supplied to the contents

of the latter being regulated by the size of the hole in the asbestos ring and the depth to which the flask is immersed in the molten metal.—W. P. S.

Oxidation; Catalytic —. I. Benzene. J. M. Weiss and C. R. Downs. J. Ind. Eng. Chem., 1920, 12, 228–232.

The catalytic oxidation of benzene is discussed, particularly the formation of maleic acid by using vanadium dioxide as the catalyst (J., 1920, 9A, 44A); in this reaction, quinone is first formed and then oxidised to maleic anhydride and, finally, to carbon dioxide and water. The temperature appears to be the controlling factor in the oxidation.

—W. P. S.

Phenol; Manufacture of — in a continuous high-pressure autoclave. K. Brown. J. Ind. Eng. Chem., 1920, 12, 279–280.

CHLOROBENZENE and sodium hydroxide solution are pumped under a pressure of 2500–3000 lb. per sq. in. through a coil of hydraulic pipe immersed in a bath of melted sodium nitrate at 700° F. (about 370° C.); the resulting sodium phenoxide is discharged from the coil through a regulated needle-valve, condensed, acidified with hydrochloric acid, and the liberated phenol distilled. (Cf. Aylsworth, J., 1918, 229A).—W. P. S.

p-Dichlorobenzene; Some derivatives of —. J. H. Crowell and L. C. Raiford. J. Amer. Chem. Soc., 1920, 42, 145–152.

p-DICHLOROBENZENESULPHONIC acid is most conveniently prepared (yield 85–90%) by the action of sulphuric acid containing 10–12% SO₃ on p-dichlorobenzene at 140°–150° C.; 2,2',5,5'-tetrachlorodiphenylsulphone, (C₆H₂Cl₄)₂SO₂, m.p. 179° C., is obtained as by-product. 2,5-Dichloro-4-nitrobenzenesulphonic acid is obtained by nitrating the sulphonic acid with a mixture of fuming nitric acid (sp. gr. 1.6) and sulphuric acid (sp. gr. 1.84). Reduction of the nitro-acid in alkaline or weakly acidic solution yields sodium 2,2',5,5'-tetrachloroazobenzene-4,4'-disulphonate.—H. W.

Nitronaphthalenesulphonic acids; Reduction of —. H. E. Fierz and P. Weissenbach. Helv. Chim. Acta, 1920, 3, 305–311.

REDUCTION of 1,6- and 1,7-nitronaphthalenesulphonic acids, either electrolytically or by means of iron and ferrous sulphate, yields the corresponding hydroxylamines. Complete reduction is only effected in weakly acid solution, e.g. by the use of ferrous sulphate. The 1,5- and 1,8-acids, however, and also 1,3,6,8-nitronaphthalenetrisulphonic acid, may be reduced electrolytically to the amino-acids in 10% sulphuric acid solution, a current density of 200–600 amp. per sq. dm. being employed between lead electrodes. (Cf. J.C.S., i., 429.)

—J. K.

a-Naphthylaminesulphonic acids; Action of sodium hydroxide on —. H. E. Fierz. Helv. Chim. Acta, 1920, 3, 318–329.

The proportions of the various products obtained by treatment of a-naphthylaminesulphonic acids with varying strengths of sodium hydroxide solution at different temperatures were determined. The chief products obtained were as follow, the figures in brackets indicating the maximum proportion obtained, with the corresponding temperature and strength of alkali employed, the time of action in all cases being 3 hrs.:—From a-naphthylamine-4-sulphonic acid, a-naphthol (50%), a-naphthol-4-sulphonic acid (51%, 280°, 10%); from a-naphthylamine-5-sulphonic acid, 1,5-dihydroxynaphthalene (60.2%, 290°, 30 or 50%), 5-amino-a-naphthol (52.4%, 250°, 30%); from a-naphthylamine-6-sulphonic acid, a-naphthol-5(?)sulphonic acid (49%, 260°, 20%); from a-naphthylamine-7-sulphonic

acid, α -naphthol-7-sulphonic acid (40% (?), 260°, 50%), 8-amino- β -naphthol (37.7%, 280°, 50%); from α -naphthylamine-8-sulphonic acid, 1,8-dihydroxynaphthalene (46.6% [70% by very rapid heating], 300°, 10%), α -naphthylamine (32.5%). Some naphthalene is always produced when naphthalene- α - or β -sulphonic acid is fused with sodium hydroxide solution. (Cf. Willson and Meyer, J., 1915, 652.)—J. K.

Production of low-temperature tar in steam power plants. Wilkens. See IIa.

Indicators and their applications. Lubs. See XXIII.

PATENTS.

Still [; Tar —]. P. C. Reilly. U.S.P. 1,310,874, 22.7.19. Appl., 28.3.14.

A METAL still is mounted within and spaced from a furnace casing, so that products of combustion from the furnace have free access to all parts of the outer surface of the still.

Rectification of benzol. C. Otto und Co., G.m.b.H., Dahlhausen. G.P. 302,584, 22.6.17.

IN order to cool thoroughly the return system of the column and to separate the high-boiling from the low-boiling products, the dephlegmator is provided with a water-jet sucking and mixing device incorporated in the cold water conduit. Part of the warm water flowing out of the dephlegmator is injected into and mixed with the inflowing cold water. —A. G.

Tar-products and resinous substances; Separation of the low-boiling constituents of —. Chem. Fabr. Worms, A.-G. G.P. 310,171, 24.1.17.

THE material is heated with metal halides containing water of crystallisation, or with kieselguhr, with or without pressure. For example, creosote heated to 200° C. without a catalyst yields 43% of light oil, while with the addition of 25% of calcium, aluminium, or magnesium chloride, or of kieselguhr, the yield rises to 32%, 30%, 31%, and 41% respectively. The yield can be still further improved by re-distillation under pressure of an indifferent gas, or by ordinary distillation after heating for some hours under a reflux condenser or in an autoclave under pressure. —B. V. S.

Separating light oils from washing oil and regenerating the latter; Apparatus for —. H. Koppers, Essen, Assignor to The Koppers Co. U.S.P. 1,323,396, 2.12.19. Appl., 8.7.13.

AN apparatus for carrying out the process described in E.P. 15,965 of 1913 (J., 1914, 411) consists of a distilling column, with an attached condenser, and a distilling chamber. Means are provided for conveying products from a point of the distilling column to the distilling chamber, and for conveying vapour from the chamber to a vapour pipe connected with the outlet of the condenser.—L. A. C.

Fractional distillation of mixtures of liquids, e.g., wash oil saturated with benzene; Apparatus for the —. C. Weirauch, Birkenhain. G.P. 316,653, 30.6.16.

THE saturated wash-oil or the like is distilled in a series of vessels heated by a mixture of air and smoke-free furnace gases conveyed to each separate vessel by parallel flues. Each vessel is heated by gases at 400°–500° C., and is provided with a fractionating column which returns the condensed liquid to the following vessel.—L. A. C.

Benzene; Catalytic oxidation of —. The Barrett Co., New York, Assignees of J. M. Weiss and C. R. Downs. E.P. 122,167, 12.11.18. (Appl., 18,550/18.) Conv., 5.1.18.

BENZENE vapour mixed with air or oxygen is passed over a catalyst of fine pumice impregnated with vanadium oxide heated to 300°–700° C. The proportions of benzene and oxygen may be varied within wide limits, but as the reaction is probably

$C_6H_6 + 7O = (CH)_2(CO_2H)_2 + HCHO + CO_2$, the optimum proportions will be those indicated by this equation.—G. F. M.

Diphenyl; Production of —. J. M. Weiss and C. R. Downs, Assignors to The Barrett Co. U.S.P. 1,322,983, 25.11.19. Appl., 5.1.18.

A MIXTURE of benzene vapour and steam is heated sufficiently to produce diphenyl.—L. A. C.

Dinitrophenol; Manufacture of —. O. Silberrad. E.P. 140,955, 10.7.19. (Appl. 17,280/19.)

PHENOL is converted into *p*-nitrosophenol, which is then nitrated by suspending 100 pts. in a solution of 200 pts. of sodium nitrate in 350 pts. of water, and running the mixture into 480 pts. of 50% sulphuric acid at 70°–80° C.; the reaction mixture is finally heated to 95° C. for 6 hours, and the resulting 1,2,4-dinitrophenol filtered off. The yield amounts to 130% of the phenol originally employed. Nitric acid (sp. gr. 1.2) may be substituted for the sodium nitrate and sulphuric acid. —G. F. M.

Phthalic anhydride. C. E. Andrews, Assignor to The Selden Co., Pittsburgh. U.S.P. 1,336,182, 6.4.20. Appl., 14.10.19.

PURE phthalic anhydride, m.p. above 130° C. (J., 1920, 57A), is claimed as a manufactured product. —L. A. C.

Naphthalene; Purification of —. R. Kutschenreuter, Berlin. G.P. 317,634, 14.8.18.

NAPHTHALENE is recrystallised from hydro-naphthalenes, and is thereby obtained extremely pure. Naphthalene is miscible in all proportions with tetrahydronaphthalene at 30° C.; at 10° C. the solubility is 1 in 10, and below 6° C. it is almost insoluble.—G. F. M.

Tetrahydro- β -thionaphthol; Preparation of —. G. Schroeter and W. Schrauth, Berlin. G.P. 299,604, 18.5.16.

TETRAHYDRONAPHTHALENE- β -SULPHONIC chloride, m.p. 55°–56° C., b.p. 194°–195° C. at 14 mm., prepared from tetrahydronaphthalene and chlorosulphonic acid, is converted by reduction with zinc dust and sulphuric or hydrochloric acid into tetrahydro- β -thionaphthol, b.p. 153°–155° C. at 26 mm. This substance has only a slight mercaptan odour, gives a crystalline mercury salt, and with dimethyl sulphate a colourless methyl ether having an aromatic odour. Its solution in caustic soda gives with chloroacetic acid tetrahydronaphtholthioglycollic acid, $C_{10}H_{11}S \cdot CH_2 \cdot CO_2H$, m.p. 133°–135° C. By the action of air on an ammoniacal alcoholic solution of the thionaphthol the disulphide $(C_{10}H_{11})_2S_2$, m.p. 87°–89° C., is formed.—G. F. M.

p-Toluenesulphonic acids halogenated in the side chain; Preparation of salts of —. Ges. für Chem. Ind. in Basel. G.P. 312,959, 24.6.17. Conv., 19.1.16.

p-TOLUENESULPHONIC acid or its dry sodium salt is treated at a high temperature with chlorine or bromine, or with substances yielding chlorine or bromine, either with or without a halogen carrier, and, according to the amount of halogen employed and the reaction temperature, the *p*-sulphonic acids of benzyl chloride or bromide or benzal chloride or bromide of their salts are obtained.—G. F. M.

Lubricants. G.P. 309,178 and 316,720. See IIa.

IV.—COLOURING MATTERS AND DYES.

Nitrous acid; Stabilisation of — in connexion with reactions carried out with this compound. Applications to diazotisation. E. Briner and R. Jonas. *Helv. Chim. Acta*, 1920, 3, 366—369.

Owing to the reversibility of the decomposition of nitrous acid into nitric acid, nitric oxide, and water, solutions of nitrous acid are stable in an atmosphere of nitric oxide under pressure. Di-nitraniline, tribromoaniline, and *p*-sulphobenzene-azo- α -naphthylamine, which are ordinarily difficult to diazotise, were successfully diazotised by condensing nitrogen trioxide (*cf.* Morgan and others; *Chem. Soc. Trans.*, 1917, 111, 187; 1918, 113, 588; *J.*, 1917, 449) in a cooled tube containing the amino compound and hydrochloric acid, and allowing the temperature to rise after sealing the tube. Picramide was not diazotised by this treatment. The value of the use of compressed air, proposed in the case of the last of the above three compounds (G.P. 143,450) is probably explicable in the same way.—J. K.

1.3-Dihydroxyisoquinoline [*o*-homophthalimide]; **Dyes derived from** —. W. Herzog. *Ber.*, 1920, 53, 564—567.

HOMOPHTHALIMIDE readily condenses with α -isatin-anilide in acetic anhydride solution to yield 1-oxy-4-isoquinoline-2'-indoleindigo

m.p. about 270° C., which is readily decomposed by dilute solutions of alkali hydroxides, but which can be converted into its leuco-compound by zinc dust and acetic acid; it gives dark violet shades on wool. Similarly, β -isatinanilide yields 1-oxy-4-isoquinoline-3'-indoleindigo, m.p. about 300° C., which is slowly decomposed by cold solutions of alkali hydroxide; it can be reduced by alkaline hydrosulphite or by zinc and acetic acid, but the vat is devoid of tinctorial properties. 1-Oxy-4-isoquinoline-2'-thionaphtheneindigo, from *o*-homophthalimide and thionaphthenequinoneanilide, has m.p. about 250° C. (decomp.). The leuco-compound has little affinity for fibres, giving fugitive cherry-red shades on wool and pale pink on cotton.—H. W.

Carminic acid. O. Dimroth and H. Kämmerer. *Ber.*, 1920, 53, 471—480.

THE close resemblance of carminic acid in absorption spectrum and tinctorial properties to kermes dye indicates that it, like the latter, is a hydroxyanthrapurpurin derivative (*J.*, 1916, 830). This is shown to be the case, since carminic acid is reduced by zinc dust and acetic acid to a leuco-compound, which is converted by air into desoxycarminic acid, and the latter can be oxidised to a diquinone, from which the parent substance is regenerated by acetic anhydride and sulphuric acid. The side-chain is considered to be $\text{C}_6\text{H}_4\text{O}_2$ and to contain four hydroxy-groups, and most probably has a sugar-like structure (although carminic acid is not a glucoside); it contains at least one asymmetric carbon atom, since carminic acid and its derivatives, but not kermesic or laccaic acids, are optically active. (*cf.* *J.C.S.*, i., 422.)—H. W.

Hydroxyanthraquinones; Acetylation of —, and **anthraquinones.** O. Dimroth, O. Friedemann, and H. Kämmerer. *Ber.*, 1920, 53, 481—487.

HYDROXYL groups in the β -position in hydroxyanthraquinones are more readily acetylated than similar groups in the α -position. β -Acetyl derivatives may be prepared by allowing calculated quantities of acetic anhydride and the hydroxy-compounds to react in cold pyridine solution; with an excess of anhydride, the α -hydroxy-groups are

also attacked. The acetylation of 1- and 2-hydroxyanthraquinones, of purpurin, Alizarin Bordeaux, and hydroxyanthrapurpurin has been investigated. Improved methods for the preparation of 1.4.9.10-anthradiquinone (Dimroth and Schultze, *J.*, 1916, 831) and its mono- and di-bromo-derivatives are described. (*cf.* *J.C.S.*, i., 443.)—H. W.

Anthocyanins present in young leaves of the grape vine. O. Rosenheim. *Biochem. J.*, 1920, 14, 178—188.

THE red pigment of the young leaves of *Vitis vinifera* is a free anthocyanidin, probably identical with cyanidin, the anthocyanidin of the purple grape. The pigment may occur in a colourless modification, termed a leuco-anthocyanin, in which form it appears to be combined with another substance, possibly a carbohydrate. The leuco-anthocyanin gives rise to anthocyanidin on treatment with strong acids.—J. C. D.

Rutin. Flavone pigment of *Eschscholtzia Californica*. C. E. Sando and H. H. Bartlett. *J. Biol. Chem.*, 1920, 41, 495—501.

THE presence of rutin in this flower has been established.—J. C. D.

Auramine as sensitiser. Bloch and Renwick. *See* XXI.

PATENTS.

Sulphur dye. C. Starobinetz, Jacksonville, Assignor to Barking Chemicals Co., Ltd., London. U.S.P. 1,318,022, 7.10.19. Appl., 8.8.18.

THE oily residue, containing various nitrotoluenes, obtained in the purification of trinitrotoluene, is fused with sodium sulphide and sulphur to obtain a brown sulphur dye.—A. J. H.

Arylaminoquinones; Preparation of mono- and di- —. M. Becke and W. and H. Suida, Vienna. G.P. 300,706, 12.6.15. (*cf.* U.S.P. 1,196,422; *J.*, 1916, 1256.)

MONOARYLAMINOQUINONES are obtained by the interaction in aqueous solution, or suspension, or by triturating together in the absence of any diluting medium, 1 mol. of a quinone of the benzene series with 1 mol. of a primary or secondary aromatic amine or a derivative thereof. By the further action of 1 mol. of the same, or another, aromatic amine diarylaminoquinones are obtained. Sulphonic acid derivatives of aromatic amines containing, in addition, an auxochrome or chromophore group, and aminoazo dyestuffs, are mentioned as suitable components. The reactions may be carried out on animal or vegetable fibres, and the arylaminoquinone then converted into its copper lake by treatment with copper acetate. The monoarylaminoquinones are soluble in ether and alcohol, only slightly soluble in water, and give yellow water-soluble bisulphite compounds. They dye wool in an acetic acid bath and on after-treatment with copper acetate give various shades of brown, fast to washing, alkali, and light. Their chief use is as intermediate products in the preparation of diarylaminoquinones, *e.g.*, 2.5-di-*p*-tolylamino-1.4-benzoquinone, which when dyed on wool and after-treated with copper acetate gives a very fast yellowish brown.—G. P. M.

Indigo derivatives; Preparation of —. Konsortium für Elektrochem. Ind. G.P. 310,197, 19.10.17.

ACETALDEHYDE or paraldehyde is allowed to react at a low temperature with a solution of indigo in concentrated sulphuric acid. The product is a greenish-blue vat dye for wool and cotton.

—A. J. H.

Monoazo dyestuffs; Manufacture of new —. Farbenfabr. vorm. F. Bayer und Co. E.P. 133,012, 22.11.17. (Appl. 17,225/17.) Conv., 25.7.16.
See G.P. 309,951 of 1917; J., 1919, 354A.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Woods; Determination of cellulose in —. W. H. Dore. J. Ind. Eng. Chem., 1920, 12, 264—269.

ALL processes involving preliminary hydrolysis in the determination of cellulose by the chlorination method result in diminished yield of α -cellulose as well as of total cellulose and, therefore, are untrustworthy. The ratio of α -cellulose to total cellulose is practically the same whether or not preliminary hydrolysis is used, showing that the highest type of cellulose is as strongly attacked as are the lower types. During the treatments incidental to the chlorination process the hemicelluloses are hydrolysed and dissolved in the filtrates and washings, and preliminary treatment with the object of removing hemicelluloses is superfluous. The greater part of the furfural-yielding complex (probably oxycellulose) remains in the residue (total cellulose) practically unaffected by the hydrolytic treatments employed; the remainder (probably xylan) is hydrolysed and dissolved during the chlorination. The significance of the term "cellulose" as applied to wood products is discussed.—W. P. S.

Celloisobiose. Ost and Prosiogel. See XVII.

PATENTS.

Cellulose esters; Preparation of —. E. Wagner, Berlin. G.P. 299,181, 4.3.14.

PARTIALLY-ACETYLATED cellulose obtained by the action of acetic acid on cellulose is further acetylated by somewhat less than double its weight of acetic anhydride, whereby the insoluble acetyl compounds are converted into higher acetylated products, which are directly soluble in the usual solvents, e.g., acetone. By this means a saving of acetic anhydride and of the catalyst, where such is employed, is effected. An example is given of the preparation of a cellulose acetate containing about 61% of acetic acid.—G. F. M.

Washing and dehydration of cellulose and cellulose preparations; Continuous —. R. Müller. G.P. 307,078, 2.3.18.

A ROTARY suction machine is combined with a device for the counter-current washing of the material with alcohol of progressively increasing strength. A pulp containing, e.g., 10% nitrocellulose can be treated by this method.—B. V. S.

Cellulose derivatives; Increasing the softness and flexibility of products made from —. Farbenfabr. vorm. F. Bayer und Co. G.P. 307,125, 9.5.17.

β -NAPHTHOL amyl ether is used. It is liquid, insoluble in water, of high b.p., and is more stable to light than the naphthol ethers hitherto proposed as substitutes for camphor. It can be used with acetyl-, nitro-, ethyl-, propyl-, and benzyl-cellulose.

—J. H. L.

Paper; Preparation of textile fibres from raw plants and production of — therefrom. Nesselanbau G.m.b.H. G.P. 318,203, 2.2.18. (See also G.P. 307,144 and 312,381; J., 1920, 13A.)

THE raw material is treated with emulsions of mineral oils or halogen derivatives of hydrocarbons. The oils may be emulsified with soaps, sulphonated oils, etc.—J. H. L.

Paper yarn; Prevention of mould growth on —. M. Sarason. G.P. 318,307, 9.2.18.

THE yarn is impregnated with cellulose extract (Zellstoffextrakt), preferably after the latter has been fermented.—J. H. L.

Caustic alkali liquors. G.P. 316,147. See XVI.

Acidifying distillery mash. G.P. 317,998. See XVIII.

Material for nitration. G.P. 300,069. See XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Aniline Black; Printing process for —. E. Jentsch. Färber-Zeit., 1920, 31, 75—76.

A GOOD black can be obtained by the following method. The padding mixture is formed of the following three solutions and is diluted to 100 kg.:— (1) 9 kg. wheat starch, 38½ kg. of water, 10½ kg. of gum tragacanth (6.5% aqueous solution), ½ kg. of Ultramarine BN are heated for one hour, cooled, and 390 g. of potassium chlorate is added. (2) 9890 g. of aniline salt, 580 g. of aniline, 9 kg. of water. (3) 4770 g. of potassium ferrocyanide, 14,930 g. of water. The fabric, prepared as usual, is printed, dried at 35°—38° C., and aged for 2—3 min. in the rapid ager, using steam as dry as possible. This is followed on the next day by chroming. The chrome bath holds 600 litres of a solution containing 1200 g. of potassium chromate and 1800 g. of sodium carbonate. For each piece of 30—38 m. is added 8 l. of a solution containing ½% potassium chromate and ¾% of sodium carbonate. After chroming at 40°—45° C. the fabric is washed, soaped, washed, and dried.—A. J. H.

Fading of dyes in daylight; Measurement of —. O. Meissner. Physik. Zeits., 1919, 20, 210—11. Chem. Zentr., 1919, 90, IV., 232.

MEASUREMENTS by Ostwald's method (J., 1919, 914A) of the effect of light on dyed fabrics showed that with dark colours during fading the proportion of white increased at the expense of the black, the purity and shade (colour tone) remaining approximately the same. In the case of light colours, the white and black both increased to approximately the same extent, and the purity was correspondingly decreased. In very light colours the black increased at the expense of the white.—A. J. H.

PATENTS.

Paper yarns and fabrics; Bleaching —. F. E. Jagenberg, Düsseldorf. G.P. 299,651, 1.9.16.

THE material is heated for 7 hrs. in a solution of a hydrosulphite, rinsed, chlorinated for 6 hrs., soured with a solution of sulphuric and hydrochloric acids, thoroughly rinsed with first warm and then hot sodium carbonate solutions and then rinsed in water. The treatment is repeated, and the product is obtained almost as white as linen or cotton, without its strength being affected. The finished yarn or fabric resembles cotton.—A. J. H.

Hanks of textile fabrics; Apparatus for treating — with liquids. W. Dürsteler, Assignor to Weidmann Dyeing Co., Ltd., Thalwil. U.S.P. 1,329,166, 27.1.20. Appl., 10.7.19.

IN a machine for the dyeing, bleaching, washing, weighting, etc. of fabrics in hank form, the hanks are carried by a frame mounted on a horizontal axis, around which it is periodically rotated through 180° in order to effect a change in the hank parts in contact with the carriers.

—A. J. H.

Fibre-treating machine. Fabric-treating machine.
H. M. Dudley, Philadelphia. U.S.P. (A) 1,335,097
and (a) 1,335,098, 30.3.20. Appl., 18.7 and
22.11.17.

(A) A DYEING machine consisting of a series of fibre chambers enclosed top and bottom by a series of perforated cones pointing inwards. The relative positions of the top and bottom can be varied. Below the bottom closure is a conical member within which are plates diverging upwards. A liquid can be forced upwards through the conical member and so through the fibre chambers. (a) A machine consisting of fabric chambers each containing a hollow perforated cylinder on which the fabric is wound. Means are provided for continuously forcing a liquid through the cylinders from the inside and so through the fabrics.—A. J. H.

Silk; Process for dyeing black and loading —
Ullnerwerk G.m.b.H. G.P. 316,751, 8.9.18.
Addition to 305,275 (J., 1918, 464 A).

"Bast soap" (boiled-off soap), artificial bast soap or a substitute therefor, is added to the loading bath in addition to water-glass.—J. H. L.

Boiling, dyeing, steaming, and washing textiles; Apparatus for — F. Gebauer, Maschinenfabr.
G.P. 315,869, 19.12.17.

A HORIZONTAL boiler is separated by partitions into a number of cylindrical compartments. Each compartment is provided with a manhole, a perforated false bottom, and valved inlet and outlet pipes at the top and bottom. Dye liquor, or the like, is circulated by means of a pump through a heater and into a main connected with each of the inlet pipes, and can thus be forced through any desired number of the compartments; the outlet pipes are also connected with a single main which returns the liquor to the pump.—L. A. C.

Printing pastes containing basic dyes; Preparation of — Farbenfabr. vorm. F. Bayer und Co.
G.P. 312,584, 28.3.16.

The printing paste is made of the colour, tannic acid, resorcinol, and a salt of a divalent metal capable of precipitating tannin. Suitable salts are acetates, formates, and lactates of zinc, cadmium, and manganese. Heavy shades can be obtained.

—A. J. H.

Hanks of yarn; Apparatus for treating — with liquids. G. S. Lord. E.P. 141,098, 5.12.18.
(Appl. 20,116/18.)

Arylaminoquinones. G.P. 300,706. See IV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Intensive manufacture of —
P. Pipereant. Monit. Sci., 1920, 10, 49—56.

VARIOUS systems of manufacture of sulphuric acid by the chamber process are critically examined, and a plant is described which is designed for the interaction of the sulphurous, nitrous, and aqueous vapours in a relatively small space. The constituents which have not entered into reaction are removed, passed through conduits wherein their characters (temperature, partial pressure of water vapour, etc.) are modified, and then introduced into a second reaction chamber, and so on, until reaction is complete.—W. J. W.

Ammonia synthesis; Electrically heated bomb for — R. O. E. Davis and H. Bryan. J. Ind. Eng. Chem., 1920, 12, 287—288.

A BOMB for the experimental synthesis of ammonia was made from a nickel-chrome iron gun forging

bored out to give a wall 1.5 in. thick, with an internal diameter of 4.25 in. and length of 15 in. A flange of the same material was screwed to the top of this shell, and to this was bolted a plate forming the head of the bomb, the closure being effected by means of recessed rings in the end of the cylinder wall and corresponding raised rings on the cap. The head plate carried the electrical heater, the catalyst tube, and inlet and outlet pipes. The sides of the bomb were protected by a fused quartz or glass tube. The heater consisted of two concentric alundum tubes wound in series with double strands of nichrome wire. The gases entered at the top of the bomb and passed down the outside of both tubes, then up through a steel tube (containing the catalyst), which slipped inside an alundum tube, and out at the top of the chamber. The catalyst tube could be withdrawn by loosening a nut; it was made gastight by means of a flange and copper washer.—C. A. M.

Gases for testing catalysts for ammonia synthesis; Purification of compressed — R. O. E. Davis.
J. Ind. Eng. Chem., 1920, 12, 289—290.

HYDROGEN and nitrogen prepared by decomposition of ammonia by an iron catalyst at 675° C. were freed from residual ammonia (about 0.04%) by scrubbing with water, and then passed through a steel-wool filter for catching oil and water spray, a palladium chamber to remove oxygen, a water trap, another steel-wool filter, two soda-lime and calcium chloride chambers, a phosphorus pentoxide chamber, and a sodamide chamber. The palladium chamber contained a central steel tube packed with steel wool mixed with 5% of palladised asbestos and fitted into an alundum tube wrapped with nichrome resistance wire. The gases were kept for about 12 secs. in contact with the palladium at 300°—400° C. The sodamide chamber, in which the last traces of carbon monoxide and water were removed, was heated to a little over 100° C.

—C. A. M.

Ammonia; Steam consumption in the manufacture of — from crude calcium cyanamide. J. Baumann. Chem.-Zeit., 1920, 44, 293—294.

Using an apparatus consisting of a horizontal autoclave, a Feldmann's column, and a locomotive boiler, it was found that 100 kg. of calcium cyanamide required 331 kg. of steam. The heat balance sheet showed a loss amounting to 7.7% of the heat supplied, which is probably to be attributed to the endothermic character of the reaction. The heat unaccounted for, in working up 13,200 kg. of calcium cyanamide, amounted to 2,366,800 cals. It is estimated that, using a plant such as that described in G.P. 251,934 (J., 1912, 1125), the steam consumption could be reduced to 126 kg. per 100 kg. of calcium cyanamide.—E. H. R.

Calcium and potassium sulphates; Formation of double salts of — at 100° C. E. Anderson and R. J. Nestell. J. Ind. Eng. Chem., 1920, 12, 243—246.

THE mean results of a series of determinations have shown that for the formation of potassium pentacalcium sulphate and of syngenite ($K_2SO_4 \cdot CaSO_4 \cdot H_2O$) at 100° C. (J., 1919, 320 A) the equilibrium concentrations are 1.05 mols. of potassium sulphate and 0.21 mol. of calcium sulphate, and 9.26 mols. of potassium sulphate and 0.142 mol. of calcium sulphate, respectively, per 1000 mols. of water. (Cf. J.C.S., June.)—C. A. M.

Calcium nitrate; Determination of nitrogen in — E. Platon. Chim. et Ind., 1920, 3, 310—312.

CALCIUM nitrate as manufactured in the Pyrenees by neutralising nitric acid, obtained from the air, with limestone, has the following average composition:— $Ca(NO_3)_2$, 76.15; $Ca(NO_3)_2$, 0.05; CaO , 0.15;

MgO, 0.30; CaCO₃, 0.55; MgCO₃, 0.35; Fe₂O₃, 0.10; Al₂O₃, 0.40; SiO₂, 0.50; and H₂O, 21.45%. Owing to its hygroscopic nature, a large sample should be taken, and 10–25 g. of this dissolved, and aliquot parts of the solution used. The best method of determining the nitrogen is by reducing the nitrate by means of Devarda's alloy in alkaline solution and distilling the ammonia.—C. A. M.

Hydrosulphite (Blankit, Redo); Evaluation of —. G. Bruhns. *Z. angew. Chem.*, 1920, 33, 92.

THE usual method of estimating hydrosulphite by titrating a solution of the salt with potassium ferricyanide, using ferrous sulphate as indicator, is subject to error and difficult to carry out on account of the rapidity with which the hydrosulphite solution is oxidised by atmospheric oxygen. The analysis can be carried out quickly and accurately in the following manner. In a porcelain dish are placed 20 c.c. of a standard solution of potassium ferricyanide, with a little ferrous sulphate sufficient to form a blue colloidal solution of Turnbull's blue, but not a precipitate. A slight excess of the hydrosulphite is weighed out in a scoop, and the salt is carefully dusted into the ferricyanide solution, with gentle stirring, until the end point is indicated by the change of colour from blue to bright reddish-yellow. The scoop is then weighed again to determine the weight of hydrosulphite used. The accuracy of the method depends on the skill in dusting the powdered salt into the ferricyanide solution. There is a small constant error due to the oxygen dissolved in the solution, but this is probably under 0.5%.

—E. H. R.

Potassium permanganate; Reaction between hydrochloric acid and —. F. P. Venable and D. H. Jackson. *J. Amer. Chem. Soc.*, 1920, 42, 237–239.

THE reaction between hydrochloric acid and potassium permanganate takes place in the two stages: $2\text{KMnO}_4 + 8\text{HCl} = 2\text{KCl} + 2\text{MnO}_2 + 4\text{H}_2\text{O} + 3\text{Cl}_2$; $\text{MnO}_2 + 4\text{HCl} = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2$. By regulating the amount of acid the reaction may be stopped at the first stage. Hydrobromic acid behaves similarly, but it will react at a concentration 0.00154N, whereas hydrochloric acid does not react if the concentration is below 0.002N.—J. F. S.

Spent oxide; Standard method of sampling and testing —. *Gas World*, 1920, 72, 320.

THE following methods have been drawn up by buyers of spent oxide, and have been approved by the National Gas Council. As the oxide is liable to change on exposure, samples sent for quotation purposes must be supplemented by samples taken during loading. On delivery, every cart or wagon must be sampled, individual samples being at once mixed, ground, and stored in air-tight receptacles, and then mixed and broken down immediately delivery is completed. The well-mixed oxide is poured several times on to a centre so as to cause even distribution of lumps and fines in the form of a cone. The cone is flattened and quartered, and two opposite quarters mixed, coned, and quartered until a convenient quantity (at least $\frac{1}{2}$ lb.) is obtained, which is then crushed until it passes entirely through a $\frac{1}{8}$ in. mesh sieve and packed in an airtight receptacle, a duplicate sample being kept for reference. For analysis the whole sample is again intimately mixed and reduced to 100 g., and then ground so that it will pass a 20-mesh sieve. Moisture is estimated by drying 5 g. for 3 hours at 100° C. in a water-oven. Sulphur and tar are determined by extracting the dried sample for 2 hours in a Soxhlet apparatus with carbon bisulphide. Air is then blown into the flask, and the extract dried for 2 hours at 100° C. in a water-oven. The flask is then heated on a sand-bath until the

sulphur just fuses, after which it is again blown out with air and weighed. Sulphur is estimated by treating the tar and sulphur residue with 15 c.c. of 95% sulphuric acid for 2 hours at 100° C. After cooling, the mixture is diluted, filtered, washed free from acid, and dried. The residue is then extracted with carbon bisulphide in a Soxhlet apparatus, fused as before, and weighed.—W. J. W.

Arsenate of calcium. I. Equilibrium in the system arsenic pentoxide, calcium oxide, and water at 35° C. (acid section). C. M. Smith. *J. Amer. Chem. Soc.*, 1920, 42, 259–265.

THE two compounds dicalcium orthoarsenate monohydrate, $\text{CaHAsO}_4 \cdot \text{H}_2\text{O}$, and monocalcium orthoarsenate, $\text{CaH}_2(\text{AsO}_4)_2$, respectively exist below and above an acid concentration corresponding to 27.5% As_2O_5 in the above-named three-component system.—J. F. S.

Arsenious acid; Reversible oxidation of —. C. Matignon and J. A. Lecanu. *Comptes rend.*, 1920 170, 941–943.

ARSENIOUS oxide, when heated with oxygen at 400°–480° C. under a pressure of 127–180 atm., is oxidised to an extent which increases with rise in temperature. A concentrated solution of arsenious acid in sodium hydroxide solution, when heated at 80° C. in oxygen under a pressure of 50 atm. for 5 hrs., is oxidised to the extent of 10.9%.—W. G.

Arsenic trichloride; Preparation of — from white arsenic and phosgene. L. H. Milligan, W. A. Baude, and H. G. Boyd. *J. Ind. Eng. Chem.*, 1920, 12, 221–223.

ARSENIC trichloride is formed almost quantitatively when phosgene is led over a mixture of arsenious oxide, 80, and carbon, 20%, heated at 200°–260° C. The reaction may be employed for the utilisation of the impure "tail gas" from phosgene manufacture, and the method of chlorination with phosgene in presence of carbon as catalyst will probably be of general application to inorganic compounds.

—W. P. S.

Mercuric oxide; Solubility of — in sodium hydroxide solutions. G. Fuseya. *J. Amer. Chem. Soc.*, 1920, 42, 368–371.

THE solubility at 25° C. increases with the concentration of sodium hydroxide, from 2.6 to 30.9 millimols. HgO per litre as the concentration of NaOH increases from 0.0096 to 2.09 mols. per litre. Hydrated mercuric oxide appears to function as a very weak acid.—E. H. R.

Rare earths. X. Purification and atomic weight of samarium. A. W. Owens, C. W. Balke, and H. C. Kremers. *J. Amer. Chem. Soc.*, 1920, 42, 515–522.

RARE earth residue from monazite sand, from which most of the cerium had been extracted, was converted into nitrate and treated with bromine to remove the remainder of the cerium. Lanthanum, praseodymium, and neodymium were removed by fractionation of the magnesium double nitrates, and finally europium and gadolinium by further fractionation with bismuth nitrate. The samarium was finally obtained as the pure anhydrous chloride. A mean of 18 determinations gave 150.43 as the atomic weight of samarium, silver being 107.88. (*Cf. J.C.S.*, ii., 316.)—E. H. R.

Carbonyl chloride; Detection and estimation of free chlorine in —. M. Delépine. *Bull. Soc. Chim.*, 1920, 27, 283–286.

A KNOWN weight of the carbonyl chloride is vaporised, the vapours are led into a 0.1% aqueous solution of potassium iodide, and the iodine liberated is titrated with standard thiosulphate solution. If the concentration of the iodide solu-

tion exceeds 0.1% there is likelihood of interaction between the oxychloride and the iodide with consequent liberation of iodine.—W. G.

Carbonyl chloride; Decomposition of — by water: estimation of escaped gases. M. Delépine, R. Douris, and L. Ville. *Bull. Soc. Chim.*, 1920, 27, 286–288.

CARBONYL chloride is only slowly decomposed by atmospheric moisture, but is rapidly decomposed by water, and less rapidly in presence of hydrochloric acid. To test the efficiency of the absorption towers used to remove the carbenyl chloride from the waste gases in its manufacture, a known volume of the air issuing from the absorption tower is bubbled through 10 c.c. of an aqueous solution containing 1 c.c. of $N/1$ sodium hydroxide and 5 c.c. of 95% alcohol. The liquid is then evaporated in a water bath to 2 c.c., 2 drops of acetic acid are added, and the evaporation is continued to dryness. The residue is treated with 2 c.c. of water, again evaporated to dryness, treated with 2 c.c. of water and the chloride present titrated with $N/40$ silver nitrate. By this means it is possible to estimate the chlorine to within 0.00005 g.—W. G.

Carbonyl chloride; Action of — on industrial iron containers. M. Delépine and L. Ville. *Bull. Soc. Chim.*, 1920, 27, 288–290.

CARBONYL chloride containing a little chlorine as impurity slowly attacks iron, forming ferric chloride. In the absence of chlorine the oxychloride will attack rust, and the ferric chloride present in commercial carbonyl chloride probably comes from this source.—W. G.

Carbonyl chloride in titanium chloride; Estimation of —. M. Delépine and J. Lafore. *Bull. Soc. Chim.*, 1920, 27, 290–292.

A MEASURED amount of the titanium chloride is decomposed by water, and the carbon dioxide resulting from the decomposition of any carbonyl chloride present is aspirated off and collected in barium hydroxide solution and then estimated volumetrically. A special arrangement of apparatus is described designed to prevent the choking of the mouth of the inlet tube by titanium oxide or oxychloride.—W. G.

Carbonyl chloride; Estimation of hydrogen chloride in —. M. Delépine, M. Monnot, H. Duval, and J. Lafore. *Bull. Soc. Chim.*, 1920, 27, 292–295.

FIVE grms. of dry finely-powdered mercury cyanide is placed in a dry flask fitted with a ground-in stopper carrying two tubes. The carbonyl chloride is introduced into the flask in a sealed bulb. The flask is evacuated and the bulb is broken. After 12 hrs. the hydrogen cyanide formed by the action of any hydrogen chloride present in the carbonyl chloride on the mercury cyanide is aspirated off and collected in 50 c.c. of $2N$ sodium hydroxide, and estimated by Denigès' method by titration with $N/20$ silver nitrate after addition of 5 c.c. of ammonia and 1 c.c. of 10% iodide solution.—W. G.

Electrical conductivity of gases during chemical reactions; Constancy of —. M. Trautz and F. A. Henglein. *Z. anorg. Chem.*, 1920, 110, 237–289.

EXPERIMENTS on the conductivity of gases during the reactions $2NO + Cl_2 \rightleftharpoons 2NOCl$; $2NO + Br_2 \rightleftharpoons 2NOBr$; $2HBr + Cl_2 \rightleftharpoons 2HCl + Br_2$, and $Cl_2 + H_2 \rightleftharpoons 2HCl$, failed to reveal evidence of the formation of free electrons.—E. H. R.

Hydrogen; Generation of — by the reaction between ferrosilicon and sodium hydroxide solution. E. R. Weaver. *J. Ind. Eng. Chem.*, 1920, 12, 232–240.

The process yields the most economical results when

about equal weights of sodium hydroxide (as 30% solution) and ferrosilicon (88% Si) are used. For a charge of 363 kg. of ferrosilicon, one-half of the sodium hydroxide solution and 28 kg. of ferrosilicon are placed in the generator (a cylindrical tank, 6 ft. 6 in. high and 6 ft. diam.), and when the temperature reaches 90° C., ferrosilicon is added at the rate of 5.6 kg. per min.; sodium hydroxide is at the same time added continuously at such a rate that the temperature remains constant. When all the solution has been added, the temperature is kept at 90° C. by the introduction of cold water until the solution contains about 20% of sodium hydroxide. The water supply is then stopped, and the reaction allowed to proceed.—W. P. S.

Iron and steam; The reversible reaction between —. E. Schreiner and F. B. Grimmes. *Z. anorg. Chem.*, 1920, 110, 311–331.

EXPERIMENTS on the equilibrium of the reaction $Fe + H_2O \rightleftharpoons FeO + H_2$ were made between 595° and 920° C., using an apparatus similar to that employed by Deville (*Comptes rend.*, 1870, 70, 1105, 1205). The values of the equilibrium constant $K = p_{H_2O}/p_{H_2}$ increase with increasing temperature. The values at lower temperatures agree fairly well with those calculated from thermodynamic principles, but at higher temperatures there is considerable discrepancy.—E. H. R.

PATENTS.

Contact process [for manufacture of sulphur trioxide]. H. E. Potts, Liverpool, Assignor to Simon-Carves, Ltd., Manchester. U.S.P., 1,335,257, 30.3.20. Appl., 17.6.18.

A STREAM of burner gas is treated with a solvent liquid, and the solution is subjected to the action of a current of air to produce a sulphur dioxide-air mixture (containing about the same proportion of sulphur dioxide as the burner gas), which is then dried and brought into contact with a catalyst to produce sulphur trioxide.—W. E. F. P.

Sulphuric acid; Catalytic manufacture of — from sulphur dioxide. G. Vortmann, Vienna. G.P. 316,858, 28.8.18. Conv., 7.9.16.

TIN oxide or tinstone, alone or mixed with inactive materials such as clay, pumice, asbestos, etc., constitutes an efficient catalyst.—W. J. W.

Sulphuric acid; Quantitative production of — from sulphates and sulphides. P. Jannasch and E. M. Alberts, Heidelberg. G.P. 318,221, 5.3.18.

A NON-REACTING material, such as quartz, is mixed with sulphates to prevent caking, and the mixture is subjected at a red heat to the action of a current of gaseous carbon tetrachloride, carbon dioxide being employed to drive the gas through the reaction chamber. In the case of sulphides, potassium or sodium chloride may be added. The sulphur is obtained in the form of sulphur chlorides, which are decomposed by water to yield sulphuric acid and hydrogen chloride. Hexachloroethane is obtained as a by-product. Suitable raw materials are gypsum, heavy spar, celestine, kainite, and pyrites, copper pyrites, and zinc blende.—W. J. W.

Sludge acid [from mineral oil refining]; Process of producing hydrochloric acid utilising —. H. M. Lasher, Assignor to Kansas City Refining Co. U.S.P. 1,337,141, 13.4.20. Appl., 12.2.19.

A SOLUTION of hydrochloric acid is produced by a counter current of water, the gas (evolved from the sludge acid) and water being brought into contact by a series of opposite periodic waves.—A. E. D.

Hydrochloric acid; Process for producing — from [acid] sludge [from treatment of mineral oils]. H. M. Lasher, Assignor to Kansas City Refining Co. U.S.P. 1,309,206, 8.7.19. Appl., 9.5.16.

THE acid sludge is mixed with sodium chloride and diluted with water until the asphaltic and tarry matters separate in the form of a scum on the surface of the liquid. The mixture is heated to a temperature not exceeding 284° C., and the hydrochloric acid vapours evolved are purified by passage through a mixture of sodium chloride and charcoal and then absorbed in water.

Hydrochloric acid; Apparatus for producing —. H. M. Lasher, Assignor to The Kansas City Refining Co. U.S.P. 1,335,743, 6.4.20. Appl., 13.7.17.

IN apparatus for producing hydrochloric acid, the gas is conducted from a still to a vertical scrubber, and thence into a horizontal absorber, provided with baffle plates, from which the solution is passed to a receiving chamber.—W. E. F. P.

Nitric acid; Process of making —. E. Thomson, Assignor to General Electric Co., New York. U.S.P. 1,337,106, 13.4.20. Appl., 6.12.18.

AS a step in the manufacture of nitric acid, nitric oxide is dissolved in nitric acid at a temperature of -40° C.—W. J. W.

Nitric acid; Method of concentrating —. Farbenfabr. vorm. F. Bayer und Co. G.P. 310,081, 7.9.18.

NITRIC acid is brought into contact with sulphuric acid in a reaction tower into which a counter-current of air is introduced to promote denitration. The sulphuric acid emanates from a concentrating plant immediately preceding the tower, and is at a sufficiently high temperature to bring about the reaction in the tower. With nitric acid of 40–50% strength, and sulphuric acid of such a concentration as to give an "outflow" acid of 70%, it is possible to produce nitric acid of 99.5% HNO₃.—W. J. W.

Nitrogen oxides; Manufacture of — from atmospheric air. E. Herman, Budapest. G.P. 305,124, 25.1.17.

NITROGEN oxides are obtained by burning carbon compounds with air by means of flameless surface combustion in a mass of aluminium nitride serving as a contact agent. The nitride may be mixed with iron oxide or nitride, copper, cobalt, nickel, manganese, chromium, calcium, barium, cerium, thorium, or titanium. The catalytic efficiency is proportional to the aluminium content of the nitride. From the combustion of 1 cb. m. of methane (8800 cal., 15°, 760 mm.) under a pressure of 10 atm., using superheated compressed air, without addition of oxygen, a yield of 380–490 g. nitric acid (100%) is obtained.—W. J. W.

Nitric oxide four-cycle gas engines; Increasing the yield from —. H. Nöh, Saarbrücken. G.P. 306,451, 29.8.16.

By washing out the exhaust gases by means of atmospheric air, the yield is increased. In a test with 70% excess of air, more than 125 g. nitric acid was obtained per cb. m. of gas.—W. J. W.

Nitric oxide; Production of — in two-cycle gas engines. H. Woll, Gersweiler - Ottenhausen. G.P. 316,677, 19.3.19.

IN order to obtain a whirling motion in the cylinder a jet of gas is introduced at the beginning of compression, followed by a jet of air as compression proceeds. The cylinder is provided with slots at its lower end for admission of air, and exhaust, and with gas and air valves at its upper end, in the compression chamber. By a uniform construction of the cylinder casing, exceptionally high temperatures are made utilisable, and the smooth surface of the walls of the compression chamber facilitates effective whirling with thorough mixing and rapid combustion.—W. J. W.

Nitrogen fixation; Process for —. K. Prinz zu Löwenstein, Neckargemünd, and F. Hauff, Stuttgart. G.P. 318,286, 24.7.15.

BARIUM carbonate is mixed with carbon, obtained free from slag by heating methane or other hydrocarbon, and the nitrogen, formed by combustion in air of the hydrogen of the hydrocarbon, is caused to combine with the carbon-barium carbonate mixture, with formation of cyanide and cyanamide.—W. J. W.

Cyanogen compounds, ammonia and the like; Production of —. G. Calvert, London. E.P. 140,484. (Appls. 17,167, 21.10.18, and 19,135, 21.11.18.)

A MIXTURE of alkali carbonate, carbon, and a catalyst (iron powder) is heated to 900°–1100° C. in the presence of nitrogen, and fresh surfaces of the heated mass are exposed to the nitrogen continuously by mechanical means arranged within the reaction chamber. The mass is removed from the chamber intermittently or continuously for the extraction of alkali cyanide, further quantities of alkali carbonate and carbon being supplied to the reaction chamber as required. Sufficient carbon is maintained in the reaction mixture to prevent sintering and welding of the catalyst, and sufficient alkali carbonate to ensure the suspension of the carbon and catalyst in the molten alkali. The alkali carbonate may be replaced by metallic sodium introduced in the molten or vaporous condition, and the carbon by carbon monoxide.—W. E. F. P.

Alkali cyanide; Method of separating — from alkali carbonate. F. J. Metzger, Assignor to Air Reduction Co., New York. U.S.P. 1,337,019, 13.4.20. Appl., 25.7.17.

Products containing alkali cyanides are extracted with a mixture of water and an organic solvent which retards hydrolytic decomposition of the cyanide, the temperature of the mass being kept below the point at which decomposition of the cyanide takes place.—W. J. W.

Nitrogen compounds from carbides; Conversion of — into ammonium compounds. R. Mewes, Berlin. G.P. 305,082, 24.3.15.

NITROGEN compounds from carbides are treated with a solution of one or more alkali salts, such as sodium or potassium chloride, or a magnesium salt, with or without heat, and the product is then heated to the sublimation temperature of the ammonium compound. The reacting substances may be subjected to the action of an electric current or, alternatively, heated to a temperature above 100° C. The process offers a convenient means of obtaining ammonium chloride and, simultaneously, sodium or potassium carbonate. At higher temperatures ammonia is produced and calcium chloride is formed.—W. J. W.

Ammonia and dicyanodiamide; Method of obtaining — from crude calcium cyanamide. Stickstoffwerke, G.m.b.H. G.P. 318,136, 18.10.18.

THE liquor obtained by treating crude calcium

cyanamido with water or mother-liquors is freed from mud, after which dicyanodiamide is recovered from it by crystallisation. From the liquor remaining after crystallisation, as well as the residual mud, ammonia is obtained. A nearly theoretical yield of nitrogen as ammonia results.—W. J. W.

Ammonia; Process of recovery of —. W. J. Chrystal, Glasgow. E.P. 140,505. (Appls. 19,940, 3.12.18, and 13,816, 31.5.19.)

RECOVERY of ammonia (from producer gas etc.), by direct absorption in sulphuric acid, is effected in two stages, the sulphate liquor being allowed to become completely neutral in the first stage, and kept at constant acidity in the second. As neutrality is attained in the first stage, the liquor is replenished by solution from the second.

—W. E. F. P.

Sulphate of ammonia; Production of —from distillation and like gases containing ammonia. E. C. R. Marks. From Soc. Franco-Belge de Fours à Coke, Brussels. E.P. 141,093, 28.11.18. (Appl. 19,677/18.)

DISTILLATION gases are cooled to 20°–25° C. to remove tar and water vapour, and are then mixed with hot ammoniacal gases obtained free from fog by passing the ammonia from the distillation of ammonia liquor through a rectifier, and the mixture is led into a closed saturator containing a solution of ammonium sulphate and sulphuric acid (33°–34° B., sp. gr. 1.296–1.308; 7% free acid), at 25°–40° C. The ammonium sulphate crystals are removed by a compressed air injector. Weak, impure sulphuric acid (50° B., sp. gr. 1.53) as well as pure acid (60° B., sp. gr. 1.71) may be used.

—W. J. W.

Ammonium sulphate; Process of raising — from saturators by means of compressed air. F. J. Collin, Dortmund. G.P. 316,596, 3.4.19.

BEFORE introducing the air it is heated, by which means incrustations are avoided.—W. J. W.

Sulphur dioxide; Process for the removal and recovery of — from gases which contain the same. Norddeutsche Hütte A.-G., and J. Behrens, Bremen. E.P. 134,555, 15.2.16. (Appl. 2280/16.)

Gas, free from ammonia and from which hydrogen sulphide has been removed by treatment with excess of sulphur dioxide, is washed with a cold, previously boiled solution of alkali sulphite, and sulphur dioxide is recovered by boiling the solution.

—W. E. F. P.

Electrolysers [for manufacture of alkali and chlorine]. G. G. Hepburn, Manchester. E.P. 141,305, 22.2.19. (Appl. 1475/20.)

An electrolyser, of the filter-press type, having mono- or bi-polar electrodes, for the manufacture of alkali and chlorine, is immersed in a non-conducting material (paraffin or carnauba wax, pitch, or naphthalene) which is not melted at the ordinary working temperature of the electrolyser, thus preventing the escape of gas or liquid. The material is melted for the insertion or removal of the electrolyser, or glycerol may be used as the immersing substance.—B. N.

Electrolytic [alkali] cells; Method of removing certain impurities from —. H. K. Moore, Assignor to Brown Co. U.S.P. 1,309,214, 8.7.19. Appl., 25.3.19.

GELATINOUS deposits of calcium and magnesium compounds formed on the porous diaphragms of electrolytic alkali cells are removed by treatment

with an acid solution, e.g., lactic acid, which reacts with the deposit to form soluble calcium and magnesium salts.

Electrolytic decomposition of chlorides. B. Cataldi, Turin. U.S.P. 1,336,281, 6.4.20. Appl., 12.5.19.

A solution of an alkali chloride is electrolysed between an insoluble anode and a mercury cathode separated from it mechanically, thus forming an alkali-metal amalgam and chlorine. Water is allowed to flow over the amalgam to form caustic soda and hydrogen, and the reaction at the surface of the amalgam is accelerated by local electrolytic action during the flow, the hydrogen and chlorine being collected.—B. N.

Titanium-oxygen compounds; Process of producing refined —. P. Farup, Assignor to Titan Co. A./S., Christiania. U.S.P. 1,325,561, 23.12.19. Appl., 21.11.16.

FERROTITANIFEROUS material is treated with hydrochloric acid to produce a solution containing the iron and an insoluble residue containing the titanium. The residue is then separated and treated with another reagent to dissolve the titanium compounds.—W. E. F. P.

Alkali-hydrate [caustic potash] solution. H. W. Charlton, New York, Assignor to American Potash Corp. U.S.P. 1,331,989, 30.3.20. Appl., 30.11.17.

A solution of crude caustic potash is obtained from greensand by a process of digestion. The product is practically free from sodium and aluminium compounds, and when dry contains 95–98% KOH, the remainder consisting of chloride, sulphate, and silicate of potassium with organic matter.

—W. E. F. P.

Soda-lime composition and method of preparing the same. R. E. Wilson, Washington, and C. P. McNeil, Astoria. U.S.P. 1,335,949, 6.4.20. Appl., 2.10.18.

A relatively slow setting cement is used in the preparation of a soda-lime reagent for the absorption of gases.—W. E. F. P.

Magnesium chloride; Method of making —. H. H. Dow and E. O. Barstow, Assignors to The Dow Chemical Co., Midland. U.S.P. 1,336,425, 13.4.20. Appl., 25.6.18.

BRINE containing a mixture of magnesium chloride and calcium chloride is treated with sodium sulphite to precipitate calcium sulphite, which is then removed.—W. F. F.

Alunite; Utilisation of native —. H. F. Chappell, New York. U.S.P. 1,336,508, 13.4.20. Appl., 11.6.18.

ALUNITE is treated with dilute sulphuric acid to dissolve the aluminium and potassium compounds, after which iron is precipitated with a cyanide, and ammonia is added to precipitate aluminium hydroxide, which is calcined to form alumina, the soluble potassium and ammonium salts being subsequently recovered in a solid form.—W. J. W.

Potassium salts; Separation of —from minerals, especially carnallite. Salzwerk Heilbronn, G. Kassel, and T. Lichtenberger. G.P. 289,746, 16.5.14.

By passing superheated steam through the molten potash mineral, the relatively heavier magnesium salt is deposited as magnesium oxide, and, in the case of carnallite, pure potassium chloride may be obtained. The separation may be effected during the decomposition of the mineral. The magnesium sulphate in kainite is completely converted into alkali sulphate by reaction with the chloride of potassium or sodium.—W. J. W.

Magnesium carbonate; Preparation of light basic —. "Lipsia," Chem. Fabr. G.P. 301,723, 7.3.16.

MAGNESIUM carbonate, $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$, is precipitated from potash end-liquors, filtered, mixed with water whilst moist to the consistency of a thin paste, and then heated to boiling. The product is completely free from potassium and chlorine, and is of a soft voluminous nature, similar to *magnesia alba*.

—W. J. W.

Absorbent for carbon dioxide; Manufacture of a highly-efficient —. R. von der Heide, Charlottenburg. G.P. 303,261, 16.1.17.

AN absorbent for carbon dioxide is prepared by adding not more than 25% (e.g., from 5 to 10%) of strongly-heated quicklime to molten anhydrous alkali hydroxide, and grinding the product to a fine powder.—L. A. C.

Alkali thiosulphates; Preparation of —. A. Clemm, Mannheim. G.P. 305,194, 18.11.17.

A SOLUTION of an alkali sulphide is allowed to flow over red-hot carbon, such as charcoal, arranged so as to offer a large surface, air or oxygen and carbon dioxide being simultaneously passed over the material. The carbonate is then separated from the thiosulphate by crystallisation. In the case of potassium salts, conversion of the carbonate into bicarbonate facilitates the separation.—W. J. W.

Hydrogen sulphide and magnesium hydroxide; Preparation of —. P. Beck, Nordhausen. G.P. (A) 307,041, 25.7.17, and (B) 307,042, 5.8.17.

(A) SULPHIDES or hydrosulphides of the alkaline earths are caused to react at normal temperature with magnesium sulphate. After separation of the alkaline-earth sulphates, pure magnesium hydroxide is obtained by decomposition of the magnesium sulphide or hydrosulphide. The alkaline-earth sulphates may be used for again producing the sulphides. (B) Alkaline-earth sulphides or hydrosulphides are decomposed with magnesium chloride, the alkaline-earth chloride produced being then caused to react with magnesium sulphate, thus reproducing magnesium chloride. The alkaline-earth sulphates so formed are reduced to sulphides by means of carbon.—W. J. W.

Calcium hydride; Manufacture of —. A. Kieselwalter, Frankfurt. G.P. 311,987, 30.7.18.

LIME or other calcium compound is fused in the electric arc in presence of hydrogen, the by-products formed being removed. The calcium hydride produced is then cooled in an atmosphere of hydrogen, which it continues to absorb during cooling.

—W. J. W.

Per-salts; Preparation of — containing a high percentage of active oxygen. Aschkenasi, Berlin. G.P. 316,997, 22.8.15. Addn. to 299,300.

THE salt to be peroxidised is evaporated repeatedly under reduced pressure with fresh quantities of hydrogen peroxide. By this means the active oxygen content of perborates can be increased from 6.2% to 13.4% and then to 19.6%, that of trisodium perphosphate from 8.2% to 13.7%, and that of disodium perphosphate from 6% to 12%.—A. R. P.

Perborates and disodium perphosphate; Manufacture of —. Aschkenasi, Berlin. G.P. 318,219, 23.11.18.

PHOSPHATES or borates are evaporated under reduced pressure with a concentrated solution of hydrogen peroxide. From sodium phosphate, disodium perphosphate with 8.8% of active oxygen is obtained, while sodium metaborate yields perborates with 10.72%, 21.7%, 22.2%, and 28.4% of active oxygen respectively.—W. J. W.

Hydrogen peroxide and the like; Process for stabilising —. M. Sarason, Berlin. G.P. (A) 318,134, (B) 318,135, and (C) 318,220, 3.7.18.

SOLUTIONS of hydrogen peroxide may be preserved at temperatures up to 70° C. by addition of 0.2% of (A) strontium hydroxide, (B) dextrose, or (C) aniline. The treatment is also effective with solutions of sodium peroxide, sodium perborate, and similar substances.—W. J. W.

Zinc compounds; Preparation of water-soluble — from roasted zinc ores. H. Reisenegger, Charlottenburg. G.P. 317,702, 14.10.17.

ROASTED zinc ores are heated with the waste liquors obtained by extracting burnt pyrites with water after the iron has been converted into ferric compounds. Zinc oxide goes into solution, with separation of the iron as hydrated oxide, and from the solution zinc salts may be obtained by evaporation and crystallisation, or metallic zinc by electrolysis, or zinc hydroxide by precipitation with a base. By using ammonia, ammonium salts are derived as by-products.—W. J. W.

Sulphurous acid or sulphur; Manufacture of — from magnesium sulphate. V. Erchenbrecher, Halle. G.P. 307,752, 16.10.17.

MAGNESIUM sulphate, in the form of a fine-grained powder, is treated with hydrogen sulphide in a rotary furnace at the minimum temperature necessary for the reaction. The decomposition yields either sulphur or sulphurous acid, dependent on the initial proportions of the reacting substances. The residual magnesia is readily hydrated and converted into carbonate.—W. J. W.

Sulphur; Process for obtaining — from sulphur dioxide and calcium sulphate. Akt.-Ges. für Anilinfabr. G.P. 300,715, 4.11.16.

SULPHUR dioxide is caused to react with carbon in a blast-furnace, the requisite temperature being maintained by combustion in oxygen of part of the carbon. The gases leaving the furnace contain free sulphur and volatile sulphur compounds, the latter being caused to react with calcium sulphate with formation of carbon dioxide, water, sulphur, and calcium sulphide. The calcium sulphate may be introduced into the furnace itself. Recovery of the sulphur from the calcium sulphate is facilitated by addition of iron oxide, alumina, clay, granite, porphyry, etc.—W. J. W.

Sulphur from crude potassium salts containing kieserite; Method of obtaining —. J. Kiermayer, and Hannoversche Kaliwerke A.-G. G.P. 310,072, 10.9.16.

SULPHUR may be obtained from potash salts by treating them, in a fused condition, with coke and wood charcoal or partly carbonised coal. Ordinary coal is not suitable on account of formation of decomposition products.—W. J. W.

Aluminium nitride; Process of producing —. Armour Fertilizer Works, Assignees of M. Shoeld. E.P. 122,829, 6.1.19. (Appl. 365/19.) Conv., 28.1.18.

SEE U.S.P. 1,274,797 of 1918; J., 1918, 662 A.

Boron derivative of pyrophosphoric acid; Manufacture of a —. B. Levin. U.S.P. 1,336,974, 13.4.20. Appl., 15.5.18.

SEE E.P. 116,735 of 1917; J., 1918, 416 A.

Ammonium carbonate. G.P. 318,236. See I.

Calcium cyanamide. G.P. 309,173. See XVI.

VIII.—GLASS; CERAMICS.

Glass; Calculating the "hardness" or expansion of —. L. Springer. *Sprechsaal*, 1920, 53, 193—195.

In Germany, the term "hardness" is frequently used with reference to thermal expansion of a glass. Actually there is no connexion between "hardness" or refractoriness and expansion, as the addition of borax will reduce expansion and increase the fusibility and "softness" of the glass. The thermal expansion may be calculated from the ultimate analysis of a glass, as previously shown by Schott and Winkelmann and Mayer and Havas respectively (J., 1911, 543). The effect of various substituted oxides on the expansion of a glass may be calculated in a similar manner.—A. B. S.

Lime-soda glasses; Properties of —. J. H. Davidson and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 222—227.

ELEVEN glasses corresponding to the formula, $a\text{Na}_2\text{O}, b\text{CaO}, 6\text{SiO}_2$, and two commercial glasses were made, and their working properties in a molten state and also under the lamp were examined. Soda-lime glasses containing more than 1.5 Na₂O and less than 0.5 CaO should be avoided, but those containing 1.0—1.4 Na₂O and 1.0—0.6 CaO are durable and work well. In most cases the addition of alumina (as felspar, china clay, or ground brick) is desirable.—A. B. S.

Lime-soda glasses; Durability of —. J. D. Canwood, J. R. Clarke, C. M. Muirhead, and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 228—237.

EXPOSURE of the glasses mentioned in the preceding abstract to water, caustic alkali, sodium carbonate, and hydrochloric acid has shown that those containing less than 0.5 CaO are too readily attacked. The replacement of soda by lime increases the resistance of the glass. For common use in automatic or semi-automatic machines glasses corresponding to 1.2—1.4 Na₂O, 0.6—0.8 CaO, 6SiO₂ are recommended.—A. B. S.

Soda-lime glasses; Heat expansion of —. S. English and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 238—242.

THE graph showing the relation between the coefficient of linear expansion and the percentage of lime in a series of pure soda-lime glasses prepared by the authors is a straight line, the glasses richest in soda having the highest expansion. Schott's well-known factors for expansion (J., 1892, 817; *Ann. Physik.*, 1894, 51, 735) do not agree with the authors' experimental results. The view that strained glass has a higher coefficient of expansion is confirmed.—A. B. S.

Lime-soda glasses; Influence of lime on the value of Young's modulus of elasticity for —. J. R. Clarke and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 260—266.

YOUNG'S modulus of elasticity was measured in a series of lime-soda glasses (J., 1919, 722A) by observing the bending of a cylindrical glass rod supported horizontally at both ends and weighted in the middle. Increase in the lime, at the expense of the soda, was accompanied by a very marked increase in the elasticity of the glass. New factors are given for calculating the elasticity of glass from its composition; Winkelmann and Schott's factors give values differing widely from the experimental results.—A. B. S.

Magnesia-soda glasses. J. H. Davidson, F. W. Hodkin, and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 275—277.

A SERIES of magnesia-soda glasses, ranging from

2Na₂O, 6SiO₂ to 0.9Na₂O, 1.1MgO, 6SiO₂, was examined. Their working and lamp-working properties are similar to those of lime-soda glasses, though the magnesia glasses are rather more difficult to manipulate; they have a greater viscosity, a tendency to stringiness, retain heat longer, have a lower coefficient of expansion for heat, and a lower annealing temperature.—A. B. S.

Magnesia-soda glasses; Annealing temperatures of —. S. English and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 278—281.

IF the magnesia content of magnesia-soda glasses is increased beyond 10%, each added increment causes a great increase in the annealing temperature of the glass. Below 10% the increase in the annealing temperature with the lime content in lime-soda glasses, is greater than with increase of the magnesia content in magnesia-soda glasses. In glasses containing equimolecular proportions of magnesia or lime, those containing magnesia are easier to anneal than those containing lime, so that dolomite appears to be a desirable substitute for ordinary limestone in commercial glasses.—A. B. S.

Glass for lampworkers; Proposed standard formula for —. F. W. and F. H. Branson. *J. Soc. Glass Tech.*, 1919, 3, 249—253.

THE following batch mixture is recommended: Sand, 1104; potash felspar, 400; limespar, 222; potassium nitrate, 213; soda ash (95%), 410; manganese dioxide (87%), 3 parts. The glass made from this mixture heated at 1340° C. for 14 hrs. is free from appreciable colour and from tendency to devitrification; fuses readily on to glasses of various degrees of hardness and composition; does not appreciably darken in the blowpipe flame; and possesses a suitable viscosity, or good working properties, for lamp-blown work.—A. B. S.

Glass for table-working. M. W. Travers. *J. Soc. Glass Tech.*, 1919, 3, 253—256.

SOME glasses used for scientific apparatus devitrify and become useless when heated in the blowpipe. The defect is sometimes more noticeable if the glass has been in stock for some time. The best glasses for table-working appear to contain 67—69% SiO₂, 3—1% Al₂O₃, 6—8% CaO, 7—6% K₂O, and 13—12% Na₂O, but such glasses require high furnace temperatures and are costly. Much of the glass tubing now made would be improved if the glass were plained at a higher temperature in a gas-fired furnace. Experiments should be made to ascertain how much lime and alumina—the latter preferably as felspar—can be present in a glass which will work satisfactorily at the blowpipe table.—A. B. S.

Glass for lamp-working purposes. J. D. Canwood, J. H. Davidson, F. W. Hodkin, and W. E. S. Turner. *J. Soc. Glass Tech.*, 1919, 3, 266—274.

A NUMBER of foreign glasses used for making lamp-working tubing were analysed and other glasses of the same ultimate composition were prepared. The best lamp-working properties were obtained with a glass containing SiO₂ 69.10%, As₂O₃ 0.10%, Al₂O₃ 3.10%, CaO 6.89%, MgO 0.20%, K₂O 6.38%, Na₂O 1.5% and MnO 0.10%. A high lime content is not necessarily detrimental, but both arsenic and antimony oxides cause the glass to blacken when heated in the blowpipe, and should be omitted from the batch-mixture. In other tests a glass containing equimolecular proportions of soda and potash worked much better than one containing only one of these oxides.—A. B. S.

Glass; Apparatus for the detection of strain in —. S. English. *J. Soc. Glass Tech.*, 1919, 3, 258—260.

A TUBULAR wooden box is provided, near its lower end, with an opening through which light passes on

to a sheet of plate glass which acts as a polariser. The light reflected from the glass is passed through the specimen to be examined, then through a Nicol prism or analyser at the upper end of the box. If a specimen of strained or badly-annealed glass is examined, bright patches of light will appear. With well-annealed glass the field remains dark.—A. B. S.

Refractory materials; Reversible expansion of —.

H. J. Hodsman and J. W. Cobb. J. Soc. Glass Tech., 1919, 3, 201—222.

THE net change in volume of a refractory material which has been heated is due to the permanent after-contraction or -expansion and to a temporary change, solely dependent on the temperature. Specimens of refractory materials (usually 20 cm. by 2.5 cm.) were heated in a silica tube contained in a horizontal tubular electric furnace, and the changes in volume were measured by noting the relative movement of marks on a silica distance-piece sliding loosely in an extension of the silica tube and on the latter. Owing to abnormalities in the expansion of the silica tube and distance piece, the method cannot be used above 1000° C. Calcined alumina, magnesia brick, carborundum, calcined kaolin, and hard calcined ball clay expand regularly over the whole range of temperature (roughly $\frac{1}{2}\%$ between 0° and 1000° C. for most materials, but over 1% for magnesia bricks). The inversion of α -to β -quartz is accompanied by a very large expansion between 500° and 600° C. and is followed by a period of constant volume between 600° and 1000° C. Bricks made of equal parts of silica and fireclay behave like silica. The contraction of fireclay bricks is intermediate between kaolin and silica. On cooling, the contraction of both clay and silica just below 600° C. exceeds the corresponding expansion on heating; a rapid cooling of ware between 600° and 500° C. may, therefore, cause cracking.

—A. B. S.

Aluminous refractories; Load behaviour of —.

A. V. Bleining. J. Amer. Ceram. Soc., 1920, 3, 155—157.

HIGHLY-ALUMINOUS refractory materials are not inherently deficient in resisting pressure at high temperatures, the deformation which occurs depending largely on their previous thermal history. A refractory material which is practically constant in volume and resists a load of 50 lb. per sq. in. at 1400° C. was made by mixing calcined Pennsylvania flint clay with artificial sillimanite prepared from North Carolina kaolin 71.6% and anhydrous alumina 28.4%, the mixture being fired at cone 20 (1530° C.). The calcined materials were mixed with fireclay, to act as a bond, and were made into bricks which were fired at cone 14 or 16 (1410° or 1460° C.). The shaping of bricks by dry-pressing reduces the burning-shrinkage and the deformation under load at high temperatures.—A. B. S.

Quartzites and silica bricks. F. Wernicke. Stahl und Eisen, 1920, 40, 432—437.

FOR the manufacture of silica bricks in Germany, rocks of three different geological formations are employed, viz., felsquartzites—marine deposits belonging to the Devonian period—which have a dense structure of closely-interlocked crystals, the individual quartz grains being relatively large, with sharply-defined edges and a characteristic wavy extinction of colour; carboniferous sandstones, consisting of medium-sized quartz crystals, some having sharply-defined edges and closely interlocked, whilst in others the edges are corroded and the crystals are separated by a small quantity of cement-like material; and glacial or "amorphous" quartzites—fresh water deposits of Tertiary origin belonging to the period of lignite formation—consisting of very small grains of quartz with rounded edges distributed uniformly through an amorphous ground-

mass of silicious gel or "basaltic" cement. All these quartzites are very rich in silica; their refractoriness corresponds to that of cone 36 (1790° C.). In the manufacture of silica bricks it is not necessary to effect a complete conversion of quartz into tridymite provided the maximum expansion is attained. With glacial quartzites, this is reached by one firing at 1450° C. without excessively prolonged heating, but silica rocks from the coal measures require two or three firings before they attain their maximum expansion, and felsquartzites continue to expand after several prolonged firings. By examination under the microscope with a magnification of only 45 diameters using polarised light, useful quartzites can be distinguished from the useless ones, as the former contain minute crystals in a glassy ground-mass, whilst the latter consist almost wholly of larger crystals or sharply-defined fragments of such crystals. For the arches of electric and other metallurgical furnaces, silica bricks should be made of glacial or Tertiary quartzites. For glass-melting furnaces, where the temperature is not so high, silica bricks made from Coal Measure quartzites are satisfactory, and may be recommended on account of their greater purity and the lesser risk of spoiling the glass. Coal Measure quartzites may also be used for silica bricks employed in regenerators, coke ovens, etc. Mixtures of Tertiary and Coal Measure quartzites are also used. Coarse crystalline quartzites are only suitable for low-grade silica bricks used in annealing furnaces, etc.—A. B. S.

Terra-cotta slips, with reference to the use of asbestos and chlorite mica. H. Wilson. J. Amer. Ceram. Soc., 1920, 3, 114—133.

THE physical properties of the body (including the shapes and sizes of the grains of grog, the manner in which the particles are compressed together, and their behaviour during drying and finishing) are of great importance in producing good glazed ware. Particles of grog which are retained on a 65-mesh sieve are liable to cause surface cracks, as the clay between them shrinks whilst the grog does not. Addition of 10—15% of chlorite mica to the engobe or body slip makes the latter ink-proof when burned and decreases cracking. Addition of asbestos to a body slip renders it difficult to apply satisfactorily by spraying, but if applied by means of a spatula it produces a very resistant surface. Addition of 3% of asbestos to a glaze appears to render the use of body slips unnecessary in many cases.—A. B. S.

Boric acid frits; Solubility of —. G. Blumenthal, jun. J. Amer. Ceram. Soc., 1920, 3, 152—154.

TESTS of nine commercial frits containing boric acid, but otherwise of unknown composition, showed that all were slightly soluble in water—apparently on account of their not having been completely melted.—A. B. S.

Clay suspensions. Smith. See XIXb.

PATENTS.

Glass furnaces. J. S. Atkinson, Stein and Atkinson, Ltd., and T. C. Moorshead, London. E.P. 141,617, 11.10.19. (Appl. 24/884/19.)

A GLASS-MELTING furnace containing a rotating table is provided with a recuperator in which the incoming gas and air are heated by means of waste gases from the furnace.—A. B. S.

Kilns of tunnel and car type; Gas, coal, or oil-fired continuous —. *Gas- or coal-fired continuous kilns and dryers of the tunnel and car type.* F. Fidler, Wigan, and J. G. Maxwell, London. E.P. (A) 141,124, and (B) 141,125, 6.1.19. (Appls. 392 and 393/19.)

(A) HEAT absorbers, consisting of cast-iron panels with zig-zag flues or of arched castings forming

flues, are built in the walls, roof, etc., of the cooling zone of a tunnel kiln, so as to absorb heat radiated from the cooling goods. The heat from the absorbers is afterwards transmitted to air forced through them by means of a fan and then utilised for various purposes. (b) Goods are dried in one or more drying tunnels built alongside a tunnel and ear kiln by clean air heated by passing it through ducts in the walls and roof and beneath the floor of the cooling zone of the tunnel kiln or through heat absorbers as described under (a).—A. B. S.

Ceramic composition. O. Gerber, Witten, Assignor to The Chemical Foundation, Inc. U.S.P. 1,336,749, 13.4.20. Appl., 27.10.13. Renewed 3.9.19.

A CERAMIC composition consists of powdered glass, china, and earthenware moulded into shape and burned.—A. B. S.

Enamelling; Process for direct — by means of highly heated gases purified from dust and tar. F. Siemens, Berlin. G.P. 317,021, 5.2.18.

THE articles to be enamelled are exposed directly to flue gases for the purpose of melting down the enamel.—G. F. M.

Refractory articles; Manufacture of —. Carborundum Co. E.P. 133,014, 13.1.19. (Appl. 927/19.) Conv., 27.9.18.

IX.—BUILDING MATERIALS.

"Iron" Portland cement, with a classification of cements made from blast-furnace slag. E. H. Lewis. Iron and Steel Inst., May, 1920. [Advance proof.]

MOST blast-furnace slags may be used for producing Portland cement, but only some of them are suitable for addition to Portland cement clinker to produce so-called "iron" Portland cement which is stronger than ordinary Portland cement. Failures in the use of blast-furnace slag as an aggregate for concrete have no relation to its suitability as a raw material for Portland cement or as an admixture to Portland cement clinker before grinding in order to make "iron" Portland cement. It is important to distinguish cement made from slags other than blast-furnace slag, as the former often contain an excess of sulphur are of poor quality.—A. B. S.

Preservation of railway sleepers; Effectiveness of sodium fluoride used as an antiseptic for the —. H. Devaux and H. Bouygues. Comptes rend., 1920, 170, 1006—1008.

ALTHOUGH sodium fluoride in 1% solution is an efficient antiseptic against such organisms as *Penicillium glaucum* and *Helicomyces fuliginosus*, it is futile to use it, by injection, for the preservation of railway sleepers, freely exposed to the weather, because it is very rapidly removed owing to the action of rain.—W. G.

Waterproof cements, concretes, and mortars; Compositions for and production of —. H. C. Badder, S. F. Burrows, and H. L. P. Allender, London. E.P. 141,113, 3.1.19. (Appl. 180/19.)

A WATERPROOF concrete or mortar is made by adding to any suitable cement or concrete, burned clay saturated with a solution of silicate, such as sodium

or potassium silicate, and zinc, magnesium, calcium or equivalent chloride.—A. B. S.

[*Slag bricks.*] *Building material.* T. F. Hoare, Bradford. E.P. 111,390, 1.2.19. (Appl. 10,937/18.)

BRICKS, blocks, slabs, or the like may be made by running molten slag into hot moulds having double walls, the space between the walls being filled with a heat-insulating material; the moulds are then allowed to cool slowly.—A. B. S.

Wood; Process and apparatus for rendering — impermeable and recovering liquids contained therein. C. Roy. E.P. 140,361, 29.7.19. (Appl. 18,775/19.) Conv., 15.3.19. Addition to 130,981.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ore; Rapid analysis of —. E. Little and W. L. Hult. J. Ind. Eng. Chem., 1920, 12, 269—273.

TO determine total iron, the hydrochloric acid solution of the ore, after reduction, is treated with an excess of standardised potassium bichromate solution, 5 g. of ammonium fluoride and 5 g. of potassium iodide are added, and the iodine liberated by the excess of bichromate is titrated with thiosulphate solution. The ammonium fluoride prevents reaction between the ferric compounds and the potassium iodide. Stannous chloride (followed by mercuric chloride) may be used to reduce the ferric salts, but reaction between the resulting mercurous chloride and iodine tends to make the results for iron too high; trustworthy results are obtained by using the Jones "reductor."—W. P. S.

Iron; Determination of — in iron ores by means of permanganate. R. Schwarz. Chem.-Zeit., 1920, 44, 310—311.

THE addition of silicic acid has no disturbing influence on the titration of iron in the method of Schwarz and Rolles (J., 1919, 179A, 821A) as was alleged by Brandt (J., 1919, 662A; 1920, 268A), nor does the simultaneous presence of oxygen affect the results. On the contrary, the presence of a silicic acid sol has a favourable influence.

—C. A. M.

Phosphorus in hematite iron; Determination of — and its commercial importance. N. D. Ridsdale. Cleveland Inst. Eng., Feb., 1920. Chem. News, 1920, 120, 219—221.

THE sample is dissolved in nitric and hydrochloric acids, silica is separated, arsenic is removed in the usual way, and the phosphoric acid and titanium are separated from the bulk of the iron by oxidising a small portion of the latter and precipitating it as basic ferric phosphate. The precipitate is dissolved in hydrochloric acid, oxidised with bromine, the titanium is separated by means of "cupferron," and the phosphoric acid is determined by the molybdate method. An alternative method consists in dissolving the iron in nitric acid with the addition of ammonium hydrogen fluoride, oxidising the filtered solution with permanganate, decomposing the excess of permanganate with ammonium oxalate, adding ammonium nitrate, ammonium chloride, and nitric acid, and precipitating the phosphoric acid (with more or less arsenic, silica, etc.) with molybdic acid reagent. The precipitate is collected, washed, dissolved in ammoniacal ammonium citrate solution, the phosphoric acid reprecipitated with molybdic acid reagent containing ferric nitrate, and the amount of phosphomolybdate precipitate determined volumetrically or gravimetrically.—W. P. S.

Phosphorus in iron, steel, ores, and slags; Critical examination of methods for the determination of —. H. Kinder. *Stahl u. Eisen*, 1920, 40, 381–387, 468–472.

MODIFICATIONS of the molybdate method and the magnesium pyrophosphate method were examined. In the molybdate method, the factor for converting the weight of the yellow precipitate into phosphorus is 1.64 when the precipitate is weighed after being dried at 105° C., and 1.723 when the precipitate is ignited at 450° C. Copper, nickel, and cobalt do not interfere with the molybdate method, chromium has but little if any effect, but silicon and tungsten must be removed previously; vanadic acid must be reduced previously with ferrous sulphate or sodium sulphite. The magnesium pyrophosphate method yields higher results than does the molybdate method; with a sample containing phosphorus equivalent to 15% P_2O_5 , the difference does not exceed 0.4%.

—W. P. S.

Iron; Crystallography of alpha and beta —. F. Giolitti. *Chem. and Met. Eng.*, 1920, 22, 585–589.

BELAIEV's work on Widmanstätten structure and other crystalline habits in slowly cooled steels (J., 1910, 954; 1912, 539) is discussed. The author's observations do not confirm Belaiev's explanation of his own results. The idea that ferrite is ejected to the periphery of homogeneous austenite on very slow cooling is not justified, as in the case of a uniform metal a Widmanstätten structure results. The suggestion that undercooling is partially responsible for Widmanstätten structure in slowly-cooled steels is not substantiated. The theory is advanced by the author that there are two distinct forms of ferrite crystals, one characteristic of regions with less than 0.4% carbon and the other of regions of higher carbon content. The former has the appearance of rounded grains separating from austenite as β -iron, and the latter are plate-like laminations forming as α -iron below 760° C. Confirmatory observations are cited to substantiate the theory, which explains the origin of all characteristic appearances of hypoeutectoid steels.

—T. H. Bu.

Blast-furnace practice; British —. F. Clements. *Iron and Steel Inst.*, May, 1920. [Advance proof.] 24 pages.

DATA supplied from seventeen furnaces working in various parts of the country are submitted and tabulated. The more important points dealt with are the chemical and thermal balance-sheets of the furnaces, the size of the various furnaces, the amounts, nature, and physical condition of the fuel or ore charged, the methods of charging, and the nature and treatment of the gas. For furnaces working under the same conditions of burden, coke, and blast, the larger furnaces show an advantage in fuel economy. Furnaces should be so worked that 50–60 lb. of carbon is burnt per sq. ft. of bosh per hour. A stack capacity of 0.75 cub. ft. per lb. of iron made per hour per sq. ft. of bosh should give effective results. The diameter of the furnace at the tuyeres should be designed to suit the bosh so that the zone of fusion coincides with the largest diameter of the furnace. Blowing plant and hot blast stoves should be of ample capacity to allow the furnace to be easily driven up to the maximum output conditions necessary to give economical results.—J. W. D.

Blast-furnace practice; Chemical and thermal conditions in —. H. E. Wright. *Iron and Steel Inst.*, May, 1920. [Advance proof.] 21 pages.

THE chemical and thermal reactions in blast-furnace practice are discussed. More attention should be

paid to the cleaning of coal for blast-furnace coke, and when poor fuel has to be used a richer ore ought to be mixed with it. The slag question in blast-furnaces, and the moisture content of the ore, require more consideration. To use oxygen in place of air in the blast is not considered advisable.—J. W. D.

Steel furnaces; Heating basic open-hearth — with a mixture of producer gas and coke oven gas. A. Schneider. *Stahl u. Eisen*, 1920, 40, 501–510.

A TILTING basic open-hearth furnace working on the production of carbon and special alloy steels has been heated by means of a mixture of producer-gas and coke-oven gas. An oxidising atmosphere is first produced over the bath by means of producer-gas so as to cause elimination of the carbon, then the coke-oven gas is introduced and an atmosphere poor in oxygen obtained, the bath being highly heated. A highly basic and reactive slag is formed which removes the phosphorus and sulphur, and this slag is continually removed by tilting the furnace so as to prevent oxidation of the added nickel, chromium, tungsten, or other elements.

—J. W. D.

Steel-making practice; Slag conditions in open-hearth basic —. J. F. Wilson. *Iron and Steel Inst.*, May, 1920. [Advance proof.] 22 pages.

HIGH slag volume retards the speed of heat transmission between the furnace and the bath, causes a blanketing effect, and thereby suppresses the "carbon boil" and prevents rapid elimination of the carbon, and also gives a high slag superheat. High slag viscosity exerts a blanketing effect. The rate of production is not only affected by these conditions, but the slow elimination of carbon tends to retain oxygen in the steel, and therefore affects the quality of the finished product. The condition of the slag influences the oxidation of the metalloids, especially the endothermic and high temperature carbon reaction, and consequently the efficiency of the furnace. A highly superheated slag gives a high furnace working temperature, and this affects the wear and tear of the furnace brickwork adversely.—J. W. D.

Silicon from slag; Reduction of — in the acid open-hearth process. B. Yaneske and G. A. Wood. *Iron and Steel Inst.*, May, 1920. [Advance proof.] 20 pages.

WHEN a highly silicious slag is in contact with the metal in the bath, reduction of silica takes place, as the slag contains more silica than is required to combine with the basic oxides present to preserve equilibrium. The formation of a highly silicious slag is facilitated by allowing the bath to remain too long at a very high temperature without additions of ore or lime. The reduction depends on the silica content of the slag and not on the temperature of the bath, and is effected by the excess of iron present, which is a far more powerful reducing agent than carbon.—J. W. D.

Iron; Blue-brittleness and ageing of —. Fettweis. *Stahl u. Eisen*, 1919, 39, 1–7, 34–40.

DRAWING of iron and steel causes the metal to age slowly at ordinary temperatures but rapidly at 300° C., thus giving rise to the phenomenon known as "blue brittleness." The author reviews recent work on this subject and draws the following conclusions. Iron drawn above 500° C. or at ordinary temperatures and then heated for a short time shows a maximum value for the tensile strength and a minimum value for the elastic limit and reduction in area between 200° and 300° C. The minimum value of the tensile strength occurs at 80° C., while the resistance in the repeated impact test is lowest between 200° and 300° C., and in the single impact

test between 400° and 500° C. If aged iron is annealed at different temperatures the mechanical properties will steadily vary with rising annealing temperature without attaining maximum or minimum values.—A. R. P.

Steel; Macrography of —. *Tests on corrosion*. H. Le Chatelier and B. Bogitch. *Rev. Mét.*, 1919, 16, 129—139.

PURE electrolytic iron was melted alone or with varying small quantities of sulphide or phosphide of iron either in magnesia crucibles exposed to the gas fumes and the air, or in silica tubes in an atmosphere of hydrogen. Specimens from each test were cut, polished, and etched with one of the following:—Stead's reagent (copper chloride and picric acid in alcohol), copper ammonium chloride in water, iodine solution, strong hydrochloric acid, 20% sulphuric acid. A series of photographs is given showing the different structures obtained. Stead's reagent colours those parts of the metal which contain least oxygen, while the other reagents attack the parts rich in oxygen. If no oxygen is present in the metal only the crystalline structure is developed by the etching agents. The authors consider that oxygen plays the same part in the macrostructure of steel as carbon does in the microstructure, and is the cause of the heterogeneity observed in slowly cooled or annealed metal, since it remains in solid solution in the portion of the metal that solidifies last. Sulphur may be detected in the metal by the production of black spots when it is treated with a piece of bromide paper moistened with sulphuric acid.—A. R. P.

Hypo-eutectic steels and alloys of similar constitution; Effect of annealing on micrographic structure of —. A. Portevin. *Rev. Mét.*, 1919, 16, 141—148.

ON rapidly quenching a mild steel from above Ac₃ nearly pure martensite is obtained; this, on annealing, gives a needle-like structure in the form of Widmanstätten figures, composed of complex ferrite-sorbite. If quenched between Ac₃ and Ac₁, however, irregular patches of martensite in a ground-mass of ferrite are formed; on annealing the former constituent is entirely replaced by sorbite without other alteration of the structure. Slower quenching results in the formation of troostite and martensite in a network of ferrite; after annealing the structure shows ferrite and sorbite, the parts which originally consisted of martensite having changed to complex ferrite-sorbite in the form of Widmanstätten figures. Similar results are obtained on annealing various bronzes and brasses.—A. R. P.

Ferromanganese as a deoxidising agent. A. Jung. *Stahl u. Eisen*, 1919, 39, 14—15.

THE statement that the addition of ferromanganese to steel in the converter in the presence of retained slag hinders the re-phosphorising of the metal is not quite correct. In a series of tests carried out on an iron containing 3% P a relatively large proportion of preheated solid ferromanganese was added to the converter. The slag contained 20—21% P₂O₅, and the lining of the converter was badly attacked. The phosphorus content of the metal in the converter increased by 0.01% P in the 5—7 min. which elapsed from the taking of the last dip sample until the ferromanganese had melted, and by 0.025% P from that point until the final sample was taken in the middle of pouring. By using the normal quantity of ferromanganese, a more resistant lining in the converter, and a lower temperature during the pouring, less phosphorus was taken up. Even when the ferromanganese was added in the liquid state, and the metal carefully skimmed, equally high results were obtained.—A. R. P.

Iron-nickel alloys; Forgeability of —. T. D. Yensen. *Amer. Inst. Min. Met. Eng.*, Feb., 1920. Blast Furnace and Steel Plant, 1920, 8, 231—234.

PURE iron-nickel alloys do not forge readily, if at all, at ordinary forging temperatures. Aluminium, carbon, magnesium, and silicon have little or no effect on the forgeability, but manganese and titanium in amounts of 2% make the alloys forgeable. The degree of forgeability of a material depends on the relative proportions of crystalline and intercrystalline or amorphous material, and the forgeability of an ingot or casting can only be ascertained by actually attempting to deform the material either by forging or rolling, or by a tensile test. The micro-structure gives no definite information. By the addition of manganese or titanium the amorphous material between the crystal grains is strengthened to such an extent that it becomes stronger than the crystalline material.—J. W. D.

Garnet; Electric furnace reduction of — [with production of ferrosilicon]. M. de K. Thompson and J. Davenport. *Chem. and Met. Eng.*, 1920, 22, 596.

ATTEMPTS were made to reduce garnet with coke in an electric furnace in order to remove the silicon and iron as ferrosilicon and produce a slag containing a higher percentage of alumina than the original garnet. Trials with red abrasive garnet containing 35% SiO₂, 27% Al₂O₃, 1.3% CaO, 2.2% MgO, and the remainder iron oxide, were encouraging, two runs averaging about 62% Al₂O₃ in the slag, whilst all the iron was removed and about half the silicon. The ferrosilicon contained 21—26% Si and 5—10% Al. An excess of 27% of coke gave as complete reduction as a 37% excess. Trials on a larger scale gave even better results. More silicon would probably be removed if the garnet and coke were ground finer than $\frac{1}{16}$ in. and briquetted with tar as a binder.—T. H. Bu.

Titanium alloys; Some electrical properties of —. M. A. Hunter and J. W. Bacon. *Trans. Amer. Electrochem. Soc.*, 1920, 391—401. [Advanced copy.]

NORWEGIAN iron, silicon-iron, nickel, copper, nickel-iron, and nickel-copper were alloyed with pure titanium, and magnetisation and hysteresis tests were made on the products. The titanium employed was prepared by reduction of titanium tetrachloride by sodium, and had m.pt. 1800° C. and sp. gr. 4.50. The magnetic quality of iron was improved by titanium so long as the latter functioned only as a cleansing agent; but when the iron itself contained more than a trace of titanium the magnetisation curve was lowered. Treatment of silicon-iron with titanium gave alloys having exceedingly high permeability and low hysteresis loss. The ageing of the titanium-treated iron and silicon-iron specimens was similar to but somewhat less than that of iron. The specific resistances of the remaining alloys were only moderately high for additions of titanium up to 5%. Beyond this point the alloys were difficult to draw and oxidised badly when run at a red heat.—W. E. F. P.

Copper; Determination of the coefficient of cubical expansion and the specific gravity of molten — and influence of the absorption of gas on the contraction of cast copper. W. Stahl. *Metall u. Erz*, 1919, 16, 443—444.

THE coefficient of cubical expansion of pure molten copper is 0.000054, whilst that of molten copper after refining by the poling process is 0.0000436. The difference is due to the absorption by the molten metal of hydrogen and carbon monoxide, which are partly evolved on cooling and partly remain in blowholes, thus causing the specific gravity to be

lowered from 8.95591 to between 8.3 and 8.6. The sp. gr. of pure copper at 1165° C. is given as 8.4322.

—A. R. P.

Copper-gold alloys; Hardness and resilience of —. A. Portevin and J. Durand. Rev. Mét., 1919, 16, 149—151.

THE Brinell hardness number of cast unquenched copper-gold alloys rises to a maximum, while the force required to break a notched bar falls to a minimum with the alloy containing 20% Cu. The fracture of this alloy shows a needle-like structure.

—A. R. P.

Zinc furnaces; Determination of the thermal conditions of —. O. Mühlhaeuser. Metall u. Erz, 1920, 17, 137—150.

TEN tables and twenty-two graphs compiled from a series of temperature measurements made with a Le Chatelier thermo-electric pyrometer are given. The figures were obtained in three furnaces of different construction, and show the variations observed between different tiers of retorts, different sections of the same furnace, and the front and rear walls of each section. The graphs illustrate the sudden changes in temperature occurring when the gas is turned off during the cleaning and recharging of the generator and during the emptying and refilling of the retorts.—A. R. P.

Tin in lead; Solubility in the solid state of —. N. Parravano and A. Scortecchi. Gazz. Chim. Ital., 1920, 50, i., 83—92.

THE electrical conductivity isotherms for the system tin-lead indicate the existence of solid solutions, the percentages of tin in the saturated solutions at different temperatures being as follows:—1.45 at 175° C., 13.5 at 170°, 12.5 at 162°, 10 at 150°, 6.5 at 100°, 5.0 at 75°, 3.0 at 50°, and 1.5 at 25° C. The conclusion that the recalcence observed with the solid alloys is due to simple supersaturation is confirmed. (Cf. J.C.S., June.)—T. H. P.

Anti-friction metal substitutes. Praetorius. Motor-wagon, 1920, 44—46. Chem.-Zeit., 1920, 44, Rep., 108.

LEAD-TIN alloys containing 13—80% Pb, 6—68% Sn, 13—15.4% Sb, 2.5—6% Cu, when tested in a 100 h.p. Mercedes motor, gave relatively good results up to a lead content of 33%, and also when the alloy contained 80% of lead.—A. R. P.

Mercury hydrosols; Mechanism of the formation and the properties of — prepared by various methods of dispersion. I. Nordlund. Koll.-Zeits., 1920, 26, 121—138.

By shaking mercury with aqueous solutions of potassium citrate ($2-7 \times 10^{-3}N$), strong, very stable sols of a reddish brown-grey colour were produced. Various other methods tried yielded sols of low stability. (Cf. J.C.S., June.)—J. F. S.

Molybdenite; Flotation of —. C. E. Oliver. Eng. and Min. J., 1920, 109, 840.

THE crushed ore (mainly quartz diorite, containing 0.5—0.75% MoS₂, distributed fairly uniformly through the rock, and iron pyrites which sometimes amounts to 3—5%) is ground in a Marcy ball mill with a mixture of pine oil and kerosene (coal oil), the mill being in closed circuit with a Dorr classifier, the overflow from which passes a 40-mesh screen. From the ball mill the pulp passes to a series of 6 Callow cells, in the first four of which ("roughing" cells) a concentrate containing 10—15% MoS₂ (and a similar proportion of pyrites) is obtained. This product passes to the two remaining ("cleaner") cells, where a concentrate containing 60—70% MoS₂ is produced. The latter is washed with water on an 80-mesh Callow screen to remove

the remaining pyrites and adhering gangue, the concentrate being removed from the under side of the screen by a spray of water and treated in a dewatering tank, from which it is passed continuously to a dryer. The final concentrate contains 85—95% MoS₂ and 2—3% FeS₂. The recovery of molybdenite rarely falls below 98% over a month's working, the oil consumed being 0.5 lb. pine oil and 1.0 lb. coal oil per ton of ore.—W. E. F. P.

Tungsten and its oxides; Reversible reactions of water on —. G. Chaudron. Comptes rend., 1920, 170, 1056—1058.

THE equilibrium of the system tungsten-water-oxides of tungsten-hydrogen at 850° C. may be expressed by the equations

The value of L_{850} for the first reaction is 2×4.4 Cals. and for the second 4 Cals.—W. G.

Iron and steam. Schreiner and Grimnes. See VII.

Cements from blast-furnace slag. Lewis. See IX.

PATENTS.

Alloy [not brittle at low temperatures]. Soc. Anon. de Commentry, Fourchambault et Decazeville, Paris. E.P. 127,243, 29.4.19. (Appl. 10,604/19.) Conv., 22.5.18.

AN alloy, suitable for use in liquefied gas machinery as it resists corrosion and retains good mechanical properties at a low temperature, is composed of Ni 40—70%, Mn 0.8 to 5%, iron the remainder. For part of the iron (5% at least must be left), and for part of the nickel (up to 7.5%) may be substituted all or any of C 0—1%, Cr 0—5%, Cu 0—10%, Co 0—10%, V 0.2—1%, Ti 0.1—0.5%.—B. M. V.

Alloy containing iron, nickel, and chromium. Soc. Anon. de Commentry, Fourchambault et Decazeville, Paris. E.P. 140,507, 17.12.18. (Appl. 21,068/18.) Conv., 19.12.17.

THE alloy contains 0.2—0.5% C, 1—2% Mn, 10—15% Cr, and 20—25% Ni, and the remainder iron, to which may be added 2—5% W. It is resistant to shock or high pressure, also to the action of strong acids, organic acids, and alkalis.—T. H. Bu.

Alloy comprising iron, nickel, chromium, tungsten (or molybdenum). Soc. Anon. de Commentry, Fourchambault et Decazeville, Paris. E.P. 140,508, 17.12.18. (Appl. 21,069/18.) Conv., 20.12.17.

THE alloy contains 0.3—0.6% C, 1—2% Mn, 10—15% Cr, 60—70% Ni, 2—5% W, and the remainder iron, to which may be added 0.2—1% V, 0.1—0.2% Ti, up to 10% Co, and 1—3% Mo to replace or partly replace the tungsten. The alloy possesses high mechanical strength at high temperatures, and is resistant to the action of chemicals.—T. H. Bu.

Alloy containing iron, nickel, and chromium. Soc. Anon. de Commentry, Fourchambault et Decazeville, Paris. E.P. 140,509, 17.12.18. (Appl. 21,070/18.) Conv., 21.12.17.

THE alloy contains 0.3—1% C, 0.5—1% Mn, 10—15% Cr, 25—40% Ni, and the remainder iron, to which may be added 2—5% W, 0.2—1% V, 0.1—0.2% Ti, up to 10% Co and 1—3% Mo. It is resistant to superheated vapours, and hot and moist gases, has good wearing properties, and its coefficient of expansion may be varied between 8 and 17×10^{-6} .

—T. H. Bu.

Steel and steel alloys; Process and apparatus for manufacturing —. W. E. Moore, Pittsburgh. U.S.P. 1,335,009, 30.3.20. Appl., 19.11.18.

STEEL is subjected to the action of an electric arc in the presence of a slag, and is then transferred to

a second furnace, where it is subjected to the heat of a shorter electric arc, in the presence of a slag of different character from that of the first slag.
—T. St.

Iron and steel; Method of carbonising — J. H. L. De Bats, Assignor to New Process Metals Corporation, Wilmington. U.S.P. 1,335,094, 30.3.20. Appl., 19.8.18.

PIECES of iron or steel to be carbonised are subjected to a preliminary heating to approximately 1100° C. to render them porous. They are then cooled, packed in carbonising material, and heated to a carbonising temperature.—T. St.

Cast-iron; Desulphurising — C. Ellis, Montclair, Assignor to Ellis-Foster Co. U.S.P. 1,335,370, 30.3.20. Appl., 9.10.17.

MOLTEN cast-iron is brought into contact with a mixture containing calcium cyanamide and calcium carbide.—T. H. Bu.

Mild steel; Desulphurisation of — H. Kaussen, Aix-La-Chapelle. G.P. 308,482, 12.3.16.

STEEL is desulphurised in the basic converter or open-hearth furnace by means of lime and iron carbide according to the equation $FeS + CaO + Fe_3C = 4Fe + CaS + CO$. The lime is derived from the excess contained in the fluid slag, and it is used with an admixture of fluid iron carbide collecting between the iron and the slag.—G. F. M.

Iron; Electrolytic extraction of metallic — directly from its ores. W. Pip, Darmstadt. G.P. 316,597, 26.6.18.

METALLIC iron is deposited electrolytically from a hot ferrous salt solution, and the ferric salt which is thereby continually formed is re-converted into ferrous salt by bringing the electrolyte into contact with spathic iron ore, whereby continuous cathodic deposition of the metal is made possible.—G. F. M.

Iron and iron alloys; Process for the preparation of pure — in powder form. Allgem. Elektrizitäts-Ges. G.P. 316,748, 24.5.16.

IRON or its alloys may be deposited electrolytically in a pulverulent form by the use of a high current density and low temperature in a bath consisting of a weak solution of a ferrous salt together with a volatile conducting salt (e.g. ammonium chloride). With a bath containing 3 pts. of ferrous chloride and 10 pts. of ammonium chloride in 100 pts. of water, and a current density of 10 amp. per sq. dm., at room temperature, a yield of 70–80% of the theoretical may be obtained. The iron deposit may be used as a catalyst or for the preparation of articles or salts of iron. If an anode of nickel-steel is employed a carbon-free, friable deposit of the alloy is obtained.—A. R. P.

Steel; Hardening bath for — E. Deisenhammer and K. Neudecker, Ratibor. G.P. 316,800, 3.7.18.

GLYCOLS, concentrated or dilute, may be used for hardening steel. The hardening effect of ethylene-glycol is increased by mixing the glycol with water.
—T. St.

Brass; Manufacture of — P. Dutoit and A. Boever, Lausanne. E.P. 132,520, 10.9.19. (Appl. 22,296/19.) Conv., 11.9.18.

BRASS made either from new metals or from skimmings, ashes, etc., is melted by submerging the raw material under a bath of molten salt of such gravity that slag will float but clean metal will sink. Barium chloride is the most suitable salt, and may be melted by an electric arc and kept molten by means of its resistance, the electrodes being so situated that the current passes through the slag and salt rather than through the molten metal.
—B. M. V.

Electrodes and welding and like rods used in soldering and depositing metals. E. H. Jones, and Alloy Welding Processes, Ltd., London. E.P. 140,568, 26.2.19. (Appl. 4848/19.)

Two or more metals or alloys are united by casting one of the metals or alloys in or about the others, or by brazing, soldering, or welding them together to form a welding rod, which is formed into an electrode by covering it with asbestos or other second-class conductor. (Cf. J., 1916, 1222; 1917, 1135; 1918, 705 A.)—B. N.

Crucible or melting pot furnaces; Tilting — Soc. des Alliages et Bronzes Forgeables, Paris. E.P. 140,709, 26.9.19. (Appl. 23,747/19.) Conv., 22.7.19.

THE tilting axis is tangent to the upper edge of the crucible over which the metal is poured, and part of the furnace body is detachable to allow the introduction of a sloping refractory channel piece through which the molten metal flows, so that a minimum surface is exposed to the atmosphere.
—T. H. Bu.

Metal smelting furnaces. A. Sinclair, Sunderland. E.P. 140,948, 2.7.19. (Appl. 16,588/19.)

A CUPOLA or similar furnace is provided with means for closing the top, and has an annular chamber surrounding the top to which air under pressure is delivered; pipes built into the walls of the furnace lead the air from this chamber to the fuel space of the furnace. The top and bottom of the cupola are also connected by passages controlled by damper slides and having in their lower parts ejectors supplied with air from the annular chamber by means of supply pipes.—J. W. D.

Furnaces for the production of mineral distillates of definite composition. W. J. Fadden, London. E.P. 141,089, 7.10.18. (Appl. 16,229/18.)

THE apparatus comprises a furnace, cooling and depositing chambers, and filters, and the draught through the cooling chambers and the filters is controlled from a position adjacent to the furnace. The furnace, into which the ore is fed by means of a conical hopper and rotating distributor, is divided into three zones, the upper zone being provided with means for admitting air for the oxidation of the distillate. The filter comprises a settling and admission chamber provided with means for removal of the deposit, a casing divided into a number of sections, each fitted with tubular filter bags, means for admitting gas and fume to each section independently, and gas outlets communicating with each filter section.—J. W. D.

Open-hearth furnaces. E. and W. Waring, Sheffield. E.P. 141,132, 8.1.19. (Appl. 532/19.)

IN an open-hearth furnace for the continuous production of steel direct from ore and scrap metal, three separate baths are maintained on different levels. The highest and largest bath is used for reducing the ore or scrap which is fed from a cupola stack over the bath; the middle and next largest bath is used for refining, while the lowest and smallest bath is in the form of an electric furnace with an undulating hearth, and is used for super-refining. Tuyères delivering to the respective baths lead from a common flue which is connected to a regenerative chamber.—J. W. D.

Furnace; Metal-heating — H. D. Williams, Pittsburgh, and W. Ahlen, Duquesne. U.S.P. 1,336,266, 6.4.20. Appl., 27.7.16.

THE furnace-heating chamber contains a number of large gas burners and, at one end, a number of small gas burners, all supplied with preheated air under pressure. The air is preheated by being passed, by means of a fan, successively through a heating chamber, a recuperator, and a second

heating chamber. A valve-controlled conduit connects the latter to the large burners, and a valve-controlled branch conduit connects the large and small burners.—T. St.

Gas crucible-furnacc. L. Tréfois, Brussels. G.P. 318,044, 15.12.17.

The heating chamber of the furnace is surrounded by two hollow-walled metal cylinders, leaving an annular space between them through which the hot burnt gases escape. The air and gas are preheated by passing them through the hollow walls of the two cylinders respectively, on their way to the burner, whilst the inner cylinder is further heated by radiation from the heating chamber itself. By this arrangement even inferior gas may be used for melting copper, nickel, silver, gold, alloys, etc.

—G. F. M.

Metals and refractory materials; Treatment of — and of tools or crucibles made thereof, and electric furnaces used therefor. G. Marsh, London. E.P. 140,885, 4.7.18. (Appl. 10,997/18.)

METALS or refractory materials, or tools or crucibles made therefrom, are heated by metal which has been melted by an electric arc, and are also electrically heated by a current passed through conductors connected to the refractory material and molten metal respectively. A pocket is made in the furnace wall to receive the metals or refractory materials.

—B. N.

Hard metal alloys, and methods of making same. G. H. Worrall, Missouri. E.P. 141,122, 6.1.19. (Appl. 374/19.)

A HARD lead alloy consisting approximately of Ba 1%, Ca 0.50%, Hg 0.25%, Sn 0.25%, Zn 0.10%, Al 0.02%, Pb 97.88% is prepared by alloying lead electrolytically with an alkali or alkaline-earth metal, increasing the hardness of this base alloy by adding a small percentage of mercury, then adding aluminium mixed with tin and zinc.—J. W. D.

Alloy; Metallic —. F. S. Hodson, Philadelphia. U.S.P. 1,335,284, 30.3.20. Appl., 12.6.18.

THE alloy contains 80–85% Zn, 0.001–2% Mn, and 0.0005–1% Ti, the remainder being mostly aluminium and copper in the ratio of about 9 to 1.

T. H. Bu.

Metal; Introducing [alloying] materials into molten —. A. Pacz, Assignor to General Electric Co., New York. U.S.P. 1,337,093, 13.4.20. Appl., 30.9.18.

IN alloying several metals very different in specific gravity with another metal, the former metals, in a finely divided condition, are made into briquettes and dropped into a molten bath of the latter metal.

—B. M. V.

Copper-bearing sands; Process of treating —. C. H. Benedict and H. C. Kenny, Lake Linden. U.S.P. 1,335,474, 30.3.20. Appl., 7.10.19.

THE sands are arranged in a bed or layer, and the copper is extracted by an ammoniacal solvent. The bed is then heated by means of steam, and water is vaporised in the heated bed under less than atmospheric pressure to recover absorbed ammonia.

—T. H. Bu.

Copper from lyes resulting from the treatment of cupriferous pyrites; Process for obtaining —. H. P. Soulié-Cottineau, Paris. E.P. 141,290, 31.10.19. (Appl. 26,819/19.)

COPPER is deposited electrolytically on iron in the form a film either by placing copper-coated iron

in a cupriferous solution or lye, or by causing the lye to fall on to the iron, when depolarisation takes place and a film of copper is deposited due to the presence of the copper-iron couple.—J. W. D.

Electrolytic process and anode. [Electrolytic deposition of copper.] F. L. Antisell, Perth Amboy. U.S.P. 1,313,246, 19.8.19. Appl., 17.8.18.

THE formation of ferric sulphate during electrolysis of solutions obtained by leaching low-grade copper ores with sulphuric acid, is reduced by dividing the anode surface into separate areas of active conductive material and of inactive non-conductive material. The anode may consist, for example, of a sheet of lead provided with a number of plugs of insulating material, the surface of the plugs being flush with the surface of the lead. The area of the active surfaces in the aggregate is appreciably smaller than the area of the cathode surface.

—B. N.

(A to D) *Electrolytic apparatus and method.* (E) *Electrolytic process and product.* M. M. Merritt, Assignor to Copper Products Co., Boston. U.S.P. (A) 1,335,174, (B) 1,335,175, (C) 1,335,176, (D) 1,335,177, 30.3.20, (E) 1,335,846, 6.4.20. Appl., (A to C) 2.8.18, (D) 18.9.18, (E) 2.11.17. (E) Renewed 4.12.19.

(A) METAL is deposited electrolytically on a stationary cathode, the level of the electrolyte being varied periodically to provide alternate immersion in and withdrawal of the cathode from the liquid without substantially changing the position of the cathode. (B) The cathode support has a provision for alternate immersion in, and withdrawal of the cathode from, the electrolyte. (C) Metal is deposited on segregated surfaces of objects by mounting them on a shaft, which is rotated during electro-deposition, so that a portion only of the surfaces to be plated is immersed in the electrolyte, and each surface is alternately immersed in and withdrawn from the liquid. (D) A mandrel, mould, or matrix is used as a cathode, and electrolytic deposition of metal is started in an alkaline electrolyte and continued in an acid electrolyte. (E) An aeroplane propeller is coated with an electrically conductive paint, and metal is deposited electrolytically upon it whilst rotating the propeller partially submerged in an electrolyte, the direction of rotation being periodically reversed.—B. N.

Copper plating; Process for —. M. Enderli, Karlsruhe. G.P. 318,402, 11.4.17.

A HOMOGENEOUS layer of copper formate, spread on the object on which a coating of copper is desired, is heated to a uniform temperature preferably in a non-oxidising atmosphere, pressure being applied either before or during this treatment. The process is designed for the production of a homogeneous deposit of copper on glass, porcelain, or metals, for the preparation of glazes in the ceramic industry, and of catalytic contact materials, and as a substitute for the electrolytic deposition of copper.

—G. F. M.

Electrolytic refining of metals or alloys containing a high percentage of foreign metal. Siemens und Halske A.-G. G.P. 317,146, 23.3.18.

SMALL quantities of acids, or their salts, of which the anions are capable of temporarily dissolving the foreign metal in the anode, are added to the electrolyte. By this means the layer of foreign metal which would otherwise form on the anode is loosened and its removal facilitated. In refining tin with a high content of lead or copper in a sulphuric acid electrolyte an addition of hydrofluosilicic acid is suitable. Hydrofluoboric acid, ethylsulphuric acid, or perchloric acid may also be used.—G. F. M.

Ores; Method of treating —. F. W. Wood, Baltimore. U.S.P. 1,331,981, 30.3.20. Appl., 24.6.14. Renewed 28.7.19.

PLASTIC ore containing 8% or more of alumina is dried to adjust its content of hygroscopic water to 14–20%, then subjected to a heavy pressure to form briquettes, which are charged into a smelting furnace. The drying prevents the ore from adhering to the compressing surfaces and facilitates the briquetting operation.—J. W. D.

Metalliferous materials; Process of treating —. Metallurgical process. H. B. Hoyland, Duluth, and G. B. Frankforter, Minneapolis. U.S.P. (a) 1,335,000 and (b) 1,335,001, 30.3.20. Appl., 15.8.13. (b) Renewed 23.10.16.

(A) THE material is treated with a solvent for the metal which is to be recovered, and the latter is then precipitated as sulphide in the presence of the gangue. The sulphide is subsequently separated from the gangue by flotation. (b) Metalliferous material is roasted to convert the metal to be recovered to oxide, and this is then, at least partially, converted to sulphide. The treated material is subsequently subjected to flotation treatment.—T. St.

Precious metals; Process for preventing distortion of — at temperatures higher than their fusing-points, and articles produced thereby. R. J. Peschko, Assignor to The Dentist's Supply Co., New York. U.S.P. 1,335,024, 30.3.20. Appl., 29.11.18.

THE precious metal or alloy is coated with a metal which is capable of being fused and oxidised at a relatively low temperature, and is then heated so that the coating metal partly fuses into the precious metal, and partly oxidises with the formation of an oxide skin. When, subsequently, the precious metal is heated to temperatures above its fusing point, the oxide skin suffices to sustain it against flow.—T. St.

Copper or copper-containing alloys; Prevention of selective corrosion of tubes and machinery parts of —. F. von Wursterberger, Assignor to Akt.-Ges. der Maschinenfabriken Escher Wyss und Co., Zürich. U.S.P. (a) 1,335,209 and (b) 1,335,210, 30.3.20. Appl., 7.6 and 11.6.19.

(A) TUBES or machinery parts of copper or copper-containing alloys in contact with water containing ions are protected by producing electrolytically in the water an easily soluble hydrolytically decomposable acid-reacting salt as anodic product, the cathodic product being carried away. (b) A salt having, upon hydrolysis, an acid reaction, is produced by electrolysis in a vessel separate from, but connected to the water supply of the machinery etc. to be protected.—T. St.

Zirconium and lead; Process for producing an alloy of —. N. Petinot, New York, Assignor to United States Ferro-Alloys Corp. U.S.P. 1,335,982, 6.4.20. Appl., 18.8.19.

ZIRCONIUM oxides and burnt lime are melted together in proportions to form calcium zirconate (CaZrO_3), sufficient carbon is added to reduce the zirconium oxide to metal and to form calcium carbide, and the mixture added to a molten bath of lead.—J. W. D.

Zirconium carbide; Process for producing alloys containing —. N. Petinot, New York, Assignor to United States Ferro-Alloys Corp. U.S.P. 1,335,983, 6.4.20. Appl., 18.8.19.

A MIXTURE of zirconium ore, iron, and carbon is melted, and then cooled rapidly, to obtain an iron alloy containing zirconium carbide or a double carbide of iron and zirconium.—J. W. D.

Alloy of iron, zirconium, and titanium, and process for the production thereof. Process for producing zirconium steel. H. C. Sicard, Buffalo, Assignor to United States Ferro-Alloys Corp. U.S.P. (a) 1,335,991 and (b) 1,335,992, 6.4.20. Appl., 18.8.19.

(A) AN alloy of iron, zirconium, titanium, and carbon is prepared by melting in an electric furnace a mixture of baddeleyite ore, rutile ore, scrap iron, and sufficient carbon both to reduce the oxides of zirconium and titanium and to combine with the zirconium, titanium, and iron to form a complex carbide in the finished alloy. (b) Zirconium steel is made by adding to molten steel an alloy prepared as described under (a).—J. W. D.

Aluminium; Solder for —. J. G. Kelly, Assignor to H. Hall, Sedalia. U.S.P. 1,336,081, 6.4.20. Appl., 27.9.18.

A SOLDER consisting of Pb 31, Sn 34, Zn 30, and Al 2%.—J. W. D.

Aluminium; Process for hardening —. H. M. Buluckian, Cleveland. U.S.P. 1,336,420, 13.4.20. Appl., 31.5.19.

ALUMINIUM is hardened by adding gum-glutin, oyster shell, and gum arabic to the molten pure metal.—W. F. F.

Aluminium; Process for increasing the resistance of — towards acid and alkaline liquids. Metallhütte Baer und Co., Kommandit-Ges., Abt. der Metallind. Schiele und Bruchsalser. G.P. 318,141, 9.3.19.

THE aluminium is covered with a layer of powdered calcium carbonate, heated to about 550° C., and the coating then united with the metal by hammering, rolling, or pressing. Aluminium thus treated is suitable for packing preserves.—G. F. M.

Zinc-aluminium alloys; Process for improving the mechanical properties of —. Hedderheimer Kupferwerk und Süddeutsche Kabelwerke A.-G. G.P. 318,346, 18.1.17.

ZINC-ALUMINIUM alloys containing 10–60% Al are submitted to mechanical working (pressing, rolling, hammering, etc.) at temperatures above that which is most suitable for rolling the zinc (120°–150° C.), and the metal is then heated to temperatures lying between 150° C. and the temperature of the conversion of the compound Al_2Zn_3 into a mixture of α - and γ -mixed crystals (e.g., 256° C. for the binary system aluminium-zinc). Alternatively, for this thermal after-treatment temperatures above the conversion point of the compound Al_2Zn_3 may be employed, but care must then be taken that the subsequent cooling occurs very slowly, otherwise, although the hardness and density may be increased, the toughness and ductility may under certain circumstances sink to very low values.—G. F. M.

Cobalt; Process of recovering —. M. J. Udy, Assignor to Haynes Stellite Co., Kokomo. U.S.P. 1,336,765, 13.4.20. Appl., 14.8.19.

ORES containing cobalt are subjected to a sulphating roast in the presence of sulphuric acid, the soluble sulphates are extracted with water, precipitated with calcium carbonate, copper removed by deposition, and sufficient lime added to form a basic insoluble sulphate. The sulphate bath is then electrolysed with an insoluble anode so that proportional quantities of the basic sulphate are dissolved as the acidity of the bath tends to rise above the normal.—J. W. D.

Metallic surfaces; Testing — for variations in composition. Allgem. Elektrizitäts-Ges. G.P. 317,603, 4.10.18.

IN order to detect local currents and potential

differences which may exist between different metals, or different portions of the surface of the same metal, particularly in connection with machines which come into contact with fluids and where electrolytic disturbances may consequently be set up resulting in the gradual destruction of the more electropositive portions of the metallic surface, the surface to be tested is covered with a suitable electrolyte kept in position in any desired spot by means of members of porous non-conducting material, the capillaries of which are filled with the electrolyte, and are provided with two electrodes which are connected on the one hand through a potentiometer and, on the other, make contact with the surface of the metal, whereby the potential difference, if any, of the galvanic element thus formed can be determined.—G. F. M.

Coating steel or iron with white metal; Process for —. E. W. Riley. E.P. 141,092, 19.11.18. (Appl. 18,982/18.)

Annealing [malleable iron castings]. A. Howgate. E.P. 141,200. (Appls. 10,637, 30.4. and 25,975, 23.10.19.)

Furnaces for drying foundry cores, annealing tin-plates and for other like purposes. W. E. Brown, W. G. Beeston, and J. J. Stevenson. E.P. 141,100, 6.12.18. (Appl. 20,231/18.)

Furnaces [for heat treatment of metal bars, etc.]. H. Fuller and R. A. Bedford. E.P. 141,403, 12.12.18. (Appl. 20,734/18.)

Metallurgical and like furnaces; Means for facilitating the repair of —. F. Hardy. E.P. 141,556, 12.6.19. (Appl. 14,813/19.)

Gold alloys. D. Belais. E.P. 141,246, 26.6.19. (Appl. 16,133/19.)

XI.—ELECTRO-CHEMISTRY.

Lead accumulator; The reactions of the —. D. A. MacInnes, L. Adler, and D. B. Jonbert. Trans. Amer. Electrochem. Soc., 1920, 383—390. [Advance copy.]

AN experimental study of the amount of sulphuric acid consumed during the discharge of a lead accumulator gave results intermediate between those corresponding to the reactions $\text{PbO}_2 + \text{Pb} + 2\text{H}_2\text{SO}_4 \rightleftharpoons 2\text{PbSO}_4 + 2\text{H}_2\text{O}$, and $\text{Pb}_2\text{O}_3 + \text{Pb} + \text{H}_2\text{SO}_4 \rightleftharpoons \text{PbSO}_4 + 2\text{PbO} + \text{H}_2\text{O}$, respectively (Pb_2O_3 represents a state of oxidation higher than PbO_2). Careful chemical analyses of the oxide formed during charging have shown it to be PbO_2 . The chemical potential of the oxide on the positive plate is identical with that of chemically prepared or electrically precipitated PbO_2 . It is suggested that intermediate oxides, such as Pb_2O_3 , or basic compounds, such as $(\text{PbO})_x\text{PbSO}_4$, may be formed during discharge.—B. N.

PATENTS.

Storage-battery plates; Process and apparatus for treating —. H. M. Martin, Assignor to Philadelphia Storage Battery Co. U.S.P. 1,301,871, 22.7.19. Appl., 14.11.14.

NEGATIVE storage-battery plates with their active material reduced to the metallic condition are dried in an atmosphere of a gas, e.g., hydrogen and/or nitrogen, which is chemically inert with respect to the active material. The dried plates may be kept for a long period without deterioration provided moisture is excluded.

Electric furnace. M. Ruthenburg, Buffalo. U.S.P. 1,335,199, 30.3.20. Appl., 4.5.18.

THE shell of the furnace is made of heat-transmitting material, and is surrounded by a resistance element substantially co-extensive with the outer surface of the shell, the element comprising a number of members individually removable for replacement.—B. N.

Electric furnace. L. Almagia and E. Guerreschi, Assignors to Soc. Anon. Ital. Gio. Ansaldo & Co., Cornigliano Ligure. U.S.P. 1,336,807, 13.4.20. Appl., 23.9.18.

ELECTRODES in the hearth and in the cover of the furnace are connected to a transformer by conducting wires. A second transformer is interposed in series in the conducting wires leading to the hearth.—B. N.

Electric furnace. S. Barfoed, Berkeley. U.S.P. 1,336,939, 13.4.20. Appl., 25.9.16.

THE furnace comprises a long water-jacketed tube with an electrode in each end. Air or gas admitted at one end is directed through the sphere of action of the electric arc, and the other end of the tube is provided with means for rapidly cooling the air or gas after it leaves the arc.—B. N.

Electric furnace. J. A. Pickens. U.S.P. 1,337,156, 13.4.20. Appl., 14.6.19.

THE furnace comprises a combustion chamber equipped with a pair of electrodes, one of which is solid, whilst the other has an aperture and a chambered opening longitudinally through its central portion. The electrodes are insulated from the surfaces of the combustion chamber.—B. N.

[*Electrical*] *ozonator.* M. W. Franklin, Assignor to General Electric Co. U.S.P. 1,337,062, 13.4.20. Appl., 3.8.16.

THE apparatus comprises a receptacle in which a cooling medium may be received, and a conducting tube passing through the receptacle and sealed in the walls. An ozone unit, arranged in the tube, comprises a dielectric (glass) tube having a closely adhering metal coating on its outer surface electrically connected to the conducting tube and a metal electrode within the glass tube, and separated from it to form a space through which an electrical discharge may be passed.—B. N.

Carbon monoxide; Electromotive activation of —. K. Hofmann, Charlottenburg. G.P. 310,782, 29.5.18.

GASES containing carbon monoxide, e.g. producer gas, are brought into contact with an electric conducting surface containing copper, such as copper gauze moistened with an alkaline electrolyte. Separated from this by the electrolyte, consisting of 5—25% caustic soda solution, is an oxygen (air) or other oxidising electrode such as manganese dioxide or nickel peroxide, or a copper plate covered with hydrated copper oxide. The electrolyte is maintained by the addition of slaked lime and the further addition of 5—15% of sodium chloride and 0.5% of sodium thiosulphate or sulphide is advantageous.

The cell gives at ordinary temperatures an E.M.F. of 0.9 volt, and by the interposition of a copper gauze to prevent the diffusion of oxygen a maximum of 1.4 volts is obtainable. (Cf. J., 1918, 765 A.)

XII.—FATS; OILS; WAXES.

Linseed oil; Determination of the hexabromide value of —. H. Wolff. *Farben-Zeit.*, 1920, 25, 1213—1214.

THE yield of hexabromido and amount of unsaponifiable matter in linseed oil are determined in one operation:—5 g. of the oil is boiled for 15 mins. beneath a reflux condenser with 30 c.c. of 5% alcoholic potassium hydroxide solution, the mass dissolved in 50 c.c. of hot water, and the soap solution rapidly cooled and transferred to a separating funnel, the flask being twice rinsed with 5 c.c. of water. It is then shaken with about 100 c.c. of petroleum spirit. The lower layer is transferred to a second separating funnel, acidified with a slight excess of hydrochloric acid, and, after the addition of about 5 g. of sodium chloride, shaken with ether. The ethereal extract is separated, dried with anhydrous sodium sulphate and filtered into a weighed flask. The solvent is evaporated on the water-bath, while a current of dry carbon dioxide is passed through the flask, and the residue of fatty acids dissolved in 50 c.c. of ether. 10 c.c. of this solution is acidified with 1 drop of glacial acetic acid in a weighed centrifugal bottle, and then with 1.0 to 1.2 c.c. of bromine, added drop by drop at -10° to 0° C. After standing for 2 hours in the freezing mixture the ethereal solution is centrifuged, the ether decanted, the precipitate stirred with about 2 c.c. of chilled ether and again centrifuged. This process is repeated, and the washed precipitate is dried at 110° C. and weighed. The amounts of hexabromide yielded by different linseed oils may vary up to 8%, and the method is therefore preferable to that of Steele and Washburn (J., 1920, 197A), in which the yields are about 3% lower, but fairly constant for different oils.—C. A. M.

Hubbard squash [Cucurbita maxima] seed oil; Composition of —. W. F. Baughman and G. S. Jamieson. J. Amer. Chem. Soc., 1920, 42, 152—157.

A SAMPLE of the cold-pressed oil had sp. gr. 0.9179 at $25^{\circ}/25^{\circ}$ C.; n_D^{25} 1.4714, iodine value (Hanus)

121.0 (liquid acids 151.2, solid acids 3.8); saponif. value 191.5 (insoluble acids 201.8, liquid acids 201.7, solid acids 210.3); mean molecular weight, insoluble acids 278.0, liquid acids 278.1, solid acids 266.8; Reichert-Meißl value, 0.37; Polonske value, 0.39; acetyl value, 27.8; acid value, 0.50; unsaponifiable matter, 1.06; soluble acids, 0.33%; insoluble acids, 91.66; unsaturated acids, 76.45; saturated acids, 18.37; solidif. pt. of insoluble acids, 29.8° — 29.85° C. The oil contains the glycerides of palmitic acid (13%), stearic acid (6%), arachidic acid (about 0.04%), oleic acid (37%), and linolic acid (44%).
—H. W.

Okra [Abelmoschus esculentus] seed oil. G. S. Jamieson and W. F. Baughman. J. Amer. Chem. Soc., 1920, 42, 166—170.

FOUR samples of cold-pressed okra seed oil have been examined; the oils vary somewhat in composition. One of them was found to contain the glycerides of palmitic acid (27.23%), stearic acid (2.75%), arachidic acid (0.05%), oleic acid (43.74%), linolic acid (26.62%), and unsaponifiable matter (0.37%). Okra seed oil, as well as oils obtained from other members of the *Malvaceae*, give the Halphen colour test.—H. W.

Fat; Extraction of — from small animals. P. Lindner. Z. Tech. Biol., 1919, 7, 213—220.

THE author investigated the possibility of recovering fat from insects and small animals, e.g. worms, larvae, weevils, etc., but the working costs appeared prohibitive. In Argentina 16—18% of fat has been obtained from cockroaches by drying, grinding, and extracting with a solvent. A further suggestion by the author was to convert faeces, on a large scale, into fat and protein in the bodies of the larvae of flies. The offspring of 14 female flies would in four months produce sufficient larvae to work up the daily faeces of 70 million human beings in a few days. Arrangements for the cultivation of the larvae are described.—J. H. L.

Cholesterol and higher fatty acids; Nephelometric values of —. F. A. Csonka. J. Biol. Chem., 1920, 41, 243—249.

THE values are influenced by the saponification process and by the presence of other substances.

PATENTS.

Oil extraction apparatus. H. Engel, Hatch End. E.P. 140,513, 20.12.18. (Appl. 21,410/18.)

MEAL or other material is extracted in a combined heating and stirring apparatus containing hollow propellers mounted on a shaft and separated by distance pieces. Steam or other heating agent is passed through the propeller blades, passing from one propeller to the next through annular passages in the distance pieces.—C. A. M.

Fat; Production of — by cultivation of mould-fungi. Kriegsausschuss für pflanzliche und tierische Öle und Fette, Berlin. G.P. 306,365, 11.5.15.

MOULD fungi and yeasts, e.g., *Oidium*, *Sachsisia*, or *Endomyces* species are cultivated in liquids containing carbohydrates and nutrient salts, e.g., molasses or beer wort, the liquids having a large surface exposed to the air. After the vegetative period formation of fat is induced by strong aeration and restricted access of moisture whilst the organisms are deprived of nutriment.—J. H. L.

Hydrocarbons; Method of making solid — emulsifiable with water. St.-Rochus-Ges.m.b.H., Charlottenburg. G.P. 308,442, 25.1.17.

SOLID hydrocarbons are mixed with wool fat and/or waxes, and the mixture heated with concentrated caustic alkali solution to above 160° C. under a pressure of not less than 5 atm. Oxidising materials, such as sodium peroxide, percarbonate, perborate, etc., or organic peroxides, may be added. Solutions of the product in liquid hydrocarbons set to pasty masses, which may be mixed with medicaments for use as ointments, etc., or may be used in the preparation of solidified oils etc.—T. St.

Oxygen-yielding detergent; Production of an —. E. Möhring, Halle. Ger. Pat. 316,753, 21.2.18.

The product is prepared by compressing a mixture containing anhydrous alkali carbonate, sodium peroxide, and sufficient anhydrous magnesium chloride to neutralise the alkali hydroxide formed by the action of water on the peroxide. Other detergents may also be incorporated. In use, the magnesium salt interacts with the sodium peroxide, forming magnesium hydroxide and sodium chloride, whilst oxygen is liberated.—J. H. L.

Catalysts for use in hydrogenation processes; Production of —. W. P. Schueck. E.P. 122,192, 6.1.19. (Appl. 353/19.) Conv., 9.1.18.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Distilled colophony. L. Gerstacker. Farben-Zeit., 1920, 25, 1170—1171.

THE residue left in the partial dry distillation of colophony, known as "distilled" colophony, is used in the manufacture of brewers' pitch and varnishes. Products obtained up to 320° C. are viscous or hard, sticky masses, whilst those obtained at higher temperatures are all hard resins. The acid and saponification values are progressively lower than those of the original colophony. The distillation products are only partially soluble in absolute alcohol and acetone, but dissolve readily in ether, benzene, chloroform, and carbon tetrachloride. This partial insolubility in acetone interferes with the test for mineral oil in rosin oil by means of a mixture of alcohol and chloroform, but on allowing the liquid to stand any turbidity due to distilled colophony adheres to the sides of the vessel in drops, whereas mineral oil rises to the surface. When saponified with alcoholic potassium hydroxide distilled colophony gives a yellow turbid solution on dilution. Rosin oil in varnishes may be detected in the unsaponifiable portion, after removal of the rosin soap, by the Liebermann-Storch reaction (acetic anhydride and sulphuric acid), but the distinctive coloration is not given by the unsaponifiable matter of distilled colophony. When varnishes are distilled pinolin and rosin oils may be detected even in the lower fractions of the distillate (220°—280° C.), but if rosin oil only appears in the higher fractions (above 280° C.) the presence of distilled colophony is indicated.—C. A. M.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc; Hot vulcanisation of —. F. Kirchhoff. Koll.-Zeits., 1920, 26, 168—173.

VULCANISATION of rubber may be effected by lead oxide or lead sulphide mixed with small quantities of sulphur and a small quantity of a sulphur-free organic catalyst.—J. F. S.

Rubber goods; Determining permanent set of —. E. L. Davies. India-rubber J., 1920, 59, 833—834.

THE average elongation at break is calculated from the results with ten sample pieces; ten other samples are then stretched to 60% of this elongation, and released after ten minutes, this operation being repeated thrice more with an interval of ten minutes each time for recovery before measurement and re-stretching. The permanent set is recorded after each of the four extensions, but the main effect is produced in the first.—D. F. T.

PATENT.

Recovering solvents. E.P. 141,210. See I.

XV.—LEATHER; BONE; HORN; GLUE.

Deliming [of limed pelt]; Velocity of —. G. Grasser. Collegium, 1919, 309, 3, 12. Chem. Zentr., 1920, 91, II., 351.

COMPARATIVE tests with 0.5% solutions of sulphuric acid, sulphuric acid plus sodium chloride, sulphuric acid plus sodium bisulphite, hydrochloric acid, ammonium chloride, hydrochloric acid plus sodium chloride, sodium bisulphate, lactic acid, acetic acid, sodium bisulphite, Neradol ND, molasses, and distilled water showed that sulphuric acid had the quickest deliming effect whilst the others followed in the order cited above. Further experiments with ammonium chloride, lactic acid, sulphuric acid plus sodium chloride, and sodium bisulphate on pieces of pelt limed in fresh limes and in limes sharpened with sodium sulphide or arsenic sulphide, showed that the rate of deliming is influenced less by the mode of liming than by the particular deliming agent employed.—D. W.

[Tannery] wetwork; Lyotropic influence and adsorption in the theory of —. H. G. Bennett. J. Soc. Leather Trades Chem., 1920, 4, 75—86.

THE view previously expressed (J., 1918, 313A, 314A) that the volume of gelatin and collagen gels is mainly determined by the net electric charge on the disperse phase resulting from ionic adsorptions and the lyotropic influence of dissolved substances in the continuous phase is further developed and the operation of these factors in the processes of soaking, liming, deliming, puering, and bating and drenching is discussed.

Sugar in tanning extracts and leather; Detection of —. G. Grasser. Collegium, 1919, 341—347. Chem. Zentr., 1920, 91, II., 352.

THE *o*-nitrophenylpropionic acid test for sugar was applied to various tanning extracts. A positive reaction was given by oak galls, knopperrn, gambier, and even by quebracho, although this contains very little sugar, and also by technical tannin. A commercial solid quebracho extract gave no reaction. The positive reaction given by quebracho and tannin was not caused by the splitting off of sugar from the tannin molecules, but by sugar actually

present as such. Catechol, pyrogallol, gallic acid, cellulose extract, formaldehyde, and synthetic tannins, such as Neradol D and ND, Ordoval G, failed to give the reaction. It is concluded that a positive reaction by tanning extracts with the reagent cannot be taken as an indication of adulteration with sugar unless there is additional evidence, and in the case of leather only when a distinctly deep blue colour is obtained with the reagent.—D. W.

Gelatin; Swelling of — in acid and alkaline solution. D. J. Lloyd. *Biochem. J.*, 1920, 14, 147—170.

THE properties of gelatin reacting as an amphoteric colloid are discussed. It is held that the structure of gels prepared from gelatin is probably that of a framework of neutral gelatin containing an interstitial fluid consisting of a solution of an ionisable gelatin salt. (*Cf. J.C.S.*, June.)—J. C. D.

PATENTS.

Tanned sponge. W. H. Allen, Detroit. U.S.P. 1,336,806, 13.4.20. Appl., 13.9.19.

SPONGE is tanned by treatment with a soluble chromium salt.—B. N.

Leather; Process for manufacturing waterproof, wear-resisting —. W. Reebberg, Hersfeld. G.P. 317,118, 3.11.18.

VEGETABLE-TANNED leather is treated with solutions of pyridine bases and impregnating materials insoluble in water, e.g. resin, asphalt, petroleum pitch, bitumen, or rubber dissolved in benzene. Leather tanned by other processes is impregnated in the same way after re-tanning with vegetable tanning materials.—D. W.

Tannin substitutes; Manufacture of —. C. Graf, Cologne. G.P. 317,462, 31.10.16.

GLAUBER'S salt, common salt, or Epsom salts are added to a mixture of sulphite-cellulose extract with an aqueous decoction of wood tar. Leather tanned with this mixture resembles that produced by a pure vegetable tannage, is plump, and has a bright colour with a dark cut.—D. W.

Leather charcoal; Preparation of high-grade — for hardening steel and iron, with simultaneous extraction of fat. M. Lindner, Dresden. G.P. 305,555, 14.4.17. Addition to 287,665 (J., 1916, 258.)

THE leather is subjected to a fat extraction process at 140°—280° C. and under 10—30 atm. pressure. By this means the leather is disintegrated and the extraction of the fat facilitated. The nitrogen content of the leather charcoal is considerably increased by this preliminary fat extraction.

—G. F. M.

Adhesives; Manufacture of —. M. O'Gorman and S. B. Schryver, London. E.P. 140,911, 17.4.19. (Appl. 9874/19.)

PROTEINS or alkali-proteins are isolated from the residues from the extraction or expression of oil from oil-seeds, especially hemp seed or castor beans, and treated with suitable bases or mixtures of bases, e.g., alkaline-earth hydroxides or magnesia, and with an alkali salt (sodium fluoride or arsenate), which will react slowly with the bases and form alkali hydroxide, and the resulting product is mixed with dilute alkali hydroxide solution.

XVI.—SOILS; FERTILISERS.

Soil acidity and alkalinity; Determination of — by indicators in the field. E. T. Wherry. J. Wash. Acad. Sci., 1920, 10, 217—223.

THE scale of values for the acidity and alkalinity of soil extracts (J., 1919, 548 A) is used in a method of determining the reaction of the soil in field tests. The following series of indicators is used: bromophenol blue, methyl red, bromocresol purple, bromothymol blue, phenol red, and phenolphthalein. About 1—2 g. of the soil is shaken with 5 c.c. of neutral salt-free water, the solid matter allowed to subside, and the clear supernatant liquid decanted and tested with the successive indicators until an intermediate colour is obtained with one indicator or opposing extremes with two overlapping indicators. The specific acidity or alkalinity in terms of p_H values may then be read from a table. (*Cf. J.C.S.*, June.)—C. A. M.

Lime requirement of a muck soil; Effect of aeration and other factors on the —. S. S. Walker. Soil Sci., 1920, 9, 77—81. (*Cf. Conner, J.*, 1919, 112 A).

THE lime requirement of a typical black muck soil was increased by air-drying, but the air-dried sample decreased in acidity during storage. When the soil was kept moist and frequently stirred for eight months the increase in acidity was decidedly less than when it was kept moist under anaerobic conditions. When the soil was neutralised with calcium carbonate and then kept moist for 8 months under either aerobic or anaerobic conditions it developed much more acidity than did the unneutralised soil under the same conditions.—W. G.

Soil; Reaction of the — as influenced by the decomposition of green manures. L. P. Howard. Soil Sci., 1920, 9, 27—39.

THERE is no indication that any acidity results from the use of rye as a cover crop during 25 years. Leguminous crops, however, during the same time considerably increased the lime requirements. On the other hand, from the treatment of uncropped soils in the laboratory with equal weights of green rye and clover it was found that the rye increased the lime requirement about twice as much as the clover.—W. G.

Chlorides in soil; Some factors influencing the quantitative determination of —. C. T. Hirst and J. E. Greaves. Soil Sci., 1920, 9, 41—51.

FOR the estimation of chlorides in soil 100 g. of the soil is shaken for 5 mins. with 500 c.c. of water, and the solution is clarified either with 2 g. of alum or by filtration through a Pasteur-Chamberland filter. Twenty c.c. portions of the clear filtrate are transferred to stoppered bottles and an excess of N/10 silver nitrate is added. After coagulation of the silver chloride by shaking in the presence of 10 c.c. of 95% alcohol, the excess silver nitrate is titrated with ammonium thiocyanate.—W. G.

Nitrifying [soil] bacteria; Isolation and study of —. W. M. Gibbs. Soil Sci., 1919, 8, 427—481.

BOTH *Nitrosomonas* and *Nitrobacter* develop readily on plates of washed agar or silicic acid gel, the latter medium being the more satisfactory for isolating the organisms. Pure cultures of either form of bacteria produce no visible growth when inoculated into bouillon. The enrichment process with both *Nitrosomonas* and *Nitrobacter* can be continued for an indefinite period of time without the slightest loss of activity of the organisms. Soil ex-

tracts used to prepare the nutrient solutions for the cultivation of *Nitrosomonas* and *Nitrobacter* did not prove toxic in either case. Sodium chloride in a concentration of 1.0% was very toxic towards *Nitrosomonas*.—W. G.

Molasses; Use of — as fertiliser in Mauritius. P. de Sornay. Bull. Assoc. Chim. Sucr., 1919, 37, 223—234.

THE application of molasses to the soil for cane cultivation has been very generally practised in Mauritius since before 1910. The results both here and in Reunion have been very satisfactory. The sugar disappears completely within about a fortnight. The beneficial effects of molasses fertilisation are most marked on plant canes, and diminish with successive ratoon crops. (Cf. Peck, J., 1910, 1467; Tempamy, J., 1911, 1463.)—J. H. L.

PATENTS.

Superphosphate manures; Apparatus for manufacture of —. H. Jones, and E. Newell and Co., Ltd., Misterton. E.P. 140,915, 3.5.19. (Appl. 11,019/19.)

HORIZONTAL, cylindrical superphosphate dens are arranged in pairs, and have each a longitudinal discharge opening in the lower portion of one side, provided with a door which hangs away from the opening when opened. The openings in two adjoining chambers are adjacent and above a common channel in which a conveyor for transporting the superphosphate operates. A rotary excavator is mounted on a carriage running on rails through the den, and the cutters of the excavator are provided with extensions leading back from the cutting edges to form sweeps or carriers. The cutters operate in a direction from the lower to the upper edge of the den opening.—W. J. W.

Calcium cyanamide; Means of emptying the furnace used in manufacture of crude —. P. Diemann, Piesteritz. G.P. 309,173, 14.2.18.

WHEN decomposition is complete, the filled, conical reaction chamber, while still red hot, is inverted so that the cover is at the bottom, and allowed to cool in this position, i.e., with the wider end downwards. By this means any burning on of the material on to the sheet-iron of the appliance is prevented.—W. J. W.

Caustic alkali liquors employed for treatment of straw, etc.; Utilisation of —. W. Colman, Charlottenburg. G.P. 316,147, 6.8.16.

THE black liquor, obtained in the treatment of straw with alkalis, is mixed with agricultural waste products and exposed to the atmosphere, by which means a stable fertiliser is produced. The caustic liquors remaining in the original material, together with the wash-waters, can be utilised for irrigation purposes.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Molasses; Determination of fine grain [sugar] in —. E. O. von Lippmann. Z. Ver. deut. Zuckerind., 1919, 44, 527. Chem. Zentr., 1920, 91, II., 498.

KALSHOVEN's method for determining the quantity of fine sugar crystals in molasses (J., 1920, 126 A) was applied to 15 final beet molasses; the results indicated that 5 contained between 1 and 5%, 7 between 5 and 10%, and 3 between 10 and 13% of sugar crystals.—J. H. L.

Fermentation; Spontaneous alcoholic — of concentrated sugar solutions [by Zygosaccharomyces]. J. Satava. Z. Zuckerind. Czechoslov., 1919, 44, 93—97.

THREE *Zygosaccharomyces* capable of fermenting

55—66% solutions of sucrose have been isolated. Organism K was found in a beet factory covering liquor ("Klärseil") of 66° Brix; its cells are elliptical or round; it does not liquefy gelatin; and in dilute solutions it ferments dextrose rapidly, and maltose and sucrose slowly. Organism S was obtained from beet factory syrup of 55° Brix; its cells are mostly oval or elongated and very unequal in size; it liquefies gelatin; and ferments dextrose rapidly, maltose slowly, and sucrose very slowly. Organism M was separated from several samples of marmalades; its cells are round; it liquefies gelatin; it ferments all the three sugars named vigorously in dilute solution; and it imparts a pleasant aroma and taste to the product, a property which may be utilised for improving the flavour of beet syrup. Pending further examination of these yeasts, they are regarded as variations of *Zygosaccharomyces Barkeri* (J., 1901, 918), which has also been found by the author to be capable of fermenting concentrated sucrose solutions.—J. P. O.

Caramel; Determination of the content of — as a means of estimating the sugar lost by superheating in the refinery. T. Koydl. Oesterr.-Ungar. Zeits. Zuckerind., 1918, 47, 16—39.

THE author proposes to estimate the amount of sugar lost during boiling by observing the increase in the colour of the product due to formation of caramel. Ehrlich's saccharan (J., 1910, 506), produced by heating sucrose to 220° C. *in vacuo*, is used as a standard, and the solutions are examined in a Stammer colorimeter. A solution of saccharan containing 10 mg. in 100 c.c. reads 2.5° Stammer; and in the production of 1 part of saccharan 4 parts of sugar is destroyed. On applying the method to the working of three massecuites obtained in the manufacture of white sugar, of raw sugar, and of after-product sugar, the amount of sugar destroyed was found to be 0.058, 0.037, and 0.833% of the dry substance respectively.—J. P. O.

Sugar factory waste water; Fermentation of — by yeast. A. Kraisy. Z. Ver. deut. Zuckerind., 1920, 163—176.

THE waste water, freed from pulp, is passed through a series of seven vessels each of about 20 cb. m. capacity. Each vessel is enclosed in a wooden casing, the top of which is provided with a sliding panel for regulating the rate of cooling. Each vessel is also provided with an air injector for agitating and aerating the contents. The first vessel is filled with waste water at 30°—36° C., and by regulating the rate of cooling, the water passes to the second vessel at 30° C. When the second vessel is one-third filled its contents are pitched with a yeast culture from a 1.5% solution of molasses containing lactic acid. The fermenting liquor passes through each succeeding vessel, 7—10 hours being required to pass through the whole series. When the whole series of vessels is in action, the second vessel, or at a later stage, the third vessel, is pitched with fermenting liquor from the seventh vessel at a rate of about 20 litres per min. The first, and subsequently the first and second vessels, serve for sedimentation of sand. The fermented liquor passes from the seventh vessel to settling tanks, and the sediment of yeast etc. is pumped to filter presses, the pressed yeast fodder being kiln-dried and ground. In the Einbeck factory 2500 kg. of yeast fodder is obtained weekly from 2500 cb. m. of waste water. The process effects a satisfactory purification of the waste water; practically all the sugar (about 0.23%) and about 90% of the total dissolved solid matter are removed. The yeast fodder contains rather a high proportion of ash (over 30%), but is richer in nitrogen than the pulp or dried slices; it is estimated to contain 5.8% of yeast.—L. E.

Melzitose; Occurrence of — in honey. C. S. Hudson and S. F. Sherwood. J. Amer. Chem. Soc., 1920, 42, 116—125.

A MANNA that forms on Douglas fir trees in British Columbia during summer droughts contains melzitose (J., 1918, 710 A), and under certain conditions this manna is collected by the bees and subsequently melzitose appears in the honey, sometimes in considerable amount. Melzitose has also been detected in other samples of honey. When a high proportion of melzitose is present in honey, it readily separates in the crystalline state; otherwise the readiest method of isolating the trisaccharide depends on fermenting away the other sugars with baker's yeast.—H. W.

Celloisobiose. H. Ost and R. Prosiegel. Z. angew. Chem., 1920, 33, 100.

A NEW biose, celloisobiose, $C_{12}H_{22}O_{11}$, has been isolated from the product of acetylation of cellulose in presence of considerable quantities of sulphuric acid at 15°—30° C. It forms fine needles with a slightly sweet taste which melt indefinitely at 165°—190° C. with evolution of gas; $[\alpha] = +23^\circ$ in aqueous solution. Its reducing power is 99% of that of maltose. It is not fermented by top-fermentation yeast, but readily yields dextrose when treated with hydrochloric acid. (Cf. J.C.S., i., 423.)—J. K.

Starch; Supposed fission of — by formaldehyde. M. Jacoby, W. von Kaufmann, A. Lewite, and H. Sallinger. Ber., 1920, 53, 681—685.

A REPLY to Woker's recent criticisms (J., 1920, 77 A). The simple explanation of the supposed diastatic action of formaldehyde lies in the fact that the latter forms a loose addition compound with starch (which does not give a blue coloration with iodine), and also modifies the physical properties of the colloid; precipitation with alcohol, or with numerous electrolytes which behave similarly, yields unchanged starch which under no conditions has suffered diastatic degradation.—H. W.

Molasses as fertiliser. De Sornay. See XVI.

PATENTS.

Centrifugal machine [for sugar]. A. H. Gibson, Salt Lake City. U.S.P. 1,336,779, 13.4.20. Appl., 21.4.15. Renewed 25.6.19.

A CENTRIFUGAL basket is carried by a vertical rotating shaft, and is provided with a bottom movable vertically, which is normally closed. Means are provided above the basket to raise and lower the bottom by the differential rotation of the basket and the said means. The bottom carries scrapers projecting upwards into the basket which engage and remove the deposit of sugar on the side walls when the bottom is lowered.—W. F. F.

Beet juices; Process for the clarification of —. E. Psenicka. G.P. 318,651, 19.3.18. Conv., 30.4.17.

RAW beet juice is mixed with sufficient saturation scum to impart a neutral or only slightly acid or alkaline reaction, and the mixture heated, a flocculent precipitate thus forming which can readily be filtered off. Subsequently the juice is treated with the necessary amount of lime, and carbonated as usual. Advantages claimed are that the separation of proteins and other non-sugars is more complete, and the amount of incrustation in the heaters and evaporators is less, than in the ordinary procedure. (Cf. J., 1919, 592 A.)—J. P. O.

Sugar cane and like crushing mills. J. Miller, and G. Fletcher and Co., Ltd. E.P. 111,078, 8.8.16. (Appl. 11,167/16.)

XVIII.—FERMENTATION INDUSTRIES.

Wine; Influence of various substances on the saturation of — with calcium sulphate. A. Bornträger. Staz. Sperim. Agrar. Ital., 1919, 52, 319—360. Chem. Zentr., 1920, 91, II., 455.

THE amount of calcium sulphate dissolved varies with the quantity of marc present, but the influence of the stalks alone is quite small. Addition of 1% of calcium sulphate was always found sufficient for saturation. The amount dissolved increases with rise in temperature to a certain degree. Saturation is attained in a short time by frequent stirring. The alcohol formed during fermentation causes the separation of a part of the dissolved calcium sulphate.—J. H. L.

Formic acid; Production of — by yeasts in media containing amides. P. Thomas. Ann. Inst. Pasteur, 1920, 34, 162—176.

THE volatile acidity produced during the culture of yeast on media containing acetamide (J., 1920, 77 A) is due partly to formic acid and partly to acetic acid formed during the fermentation. The total volatile acidity and the relative proportions of the two acids vary with the conditions. (Cf. J.C.S., June.)—W. G.

Acetone and n-butyl alcohol; Intermediate substances produced in fermentation method for preparation of —. J. Reilly, W. J. Hickinbottom, F. R. Henley, and A. C. Thaysen. Biochem. J., 1920, 14, 229—251.

THE chief intermediate products appear to be acetic and butyric acids. The possible mechanism of the formation of acetone and n-butyl alcohol during this fermentation process is discussed. Lactic acid may be produced in an infected mash. (Cf. J.C.S., June.)—J. C. D.

Soya bean urcase. A. W. Dox. Amer. J. Pharm., 1920, 92, 153—157.

THE urcase activity of soya beans of different varieties and crops was determined by mixing 1 g. of the powdered seed with 15 c.c. of water, and 10 c.c. of 1% urea solution, and titrating the liberated ammonia after 30 mins. at 40° C. The amounts of N/10 hydrochloric acid required by 37 samples ranged from 11.1 to 20.2 c.c. The differences in the urcase activity shown by different varieties of the beans did not stand in any relationship to the protein content or germinating power of the seed.—C. A. M.

Alcoholometric tables applicable to alcohol denatured with wood spirit and naphtha. O. Chénéau. Bull. Assoc. Chim. Sucr., 1919, 37, 213—222.

XIXA.—FOODS.

Baking properties of flours. T. von Fellenberg. Mitt. Lebensmittellunters. u. Hyg., 1919, 10, 229—260. Chem. Zentr., 1920, 91, 11., 412—413.

A STUDY was made of the baking properties of artificial flour mixtures made up of 10% of a protein (gliadin, glutenin, egg albumin, casein, or gelatin), 86% of starch (from wheat, rye, maize, rice, or potatoes), and the balance of sugar and mineral salts. In working them into dough 1.5% of sodium chloride and 2% of yeast were added. The dough was allowed to ferment for 3 hours at 32° C. and then baked at 130°—135° C. Comparative experiments were also made on commercial flours, and the effect of baking powders was investigated. The following conclusions are drawn:—The baking property of flour is chiefly due to gliadin, which alone determines the increase in volume. Differences in the gliadin-content account for the superiority of wheat flour over rye flour and of this over barley flour. Substitution of egg albumin or gelatin for gliadin gives fluid doughs which cannot be kneaded; with egg-albumin the dough rises well, but not with gelatin. Casein gives a dense bread, and with pectin the dough does not rise. The baking property of flour is also affected by the kind of starch present, wheat starch being the best. Addition of lecithin increases the volume of the loaf, but soluble polysaccharides impair the baking properties. Two stages may be distinguished in bread-making, *viz.*, the fermentation of the dough and the baking process proper. The larger the proportion of bran in a flour, the higher will as a rule be the acidity, the protein content, and the proteolytic activity of the flour; with increase in these factors the gluten becomes more fluid during fermentation of the dough, the duration of fermentation is lessened, and the volume of the loaf increased. In the case of bread made with the aid of baking powders, without fermentation of the dough, the volume varies directly with the elasticity and extensibility of the gluten and the capacity of the flour for retaining water, and inversely with the stiffness of the dough. It depends upon the content of proteins, especially gliadin, and is unfavourably affected by soluble polysaccharides. The capacity of the flour for retaining water depends on the presence of substances which dissolve and swell in water, *viz.*, proteins, soluble carbohydrates, husk constituents, and mineral salts.—J. H. L.

Potatoes; Melanin-value of —. H. Haehn. Z. Spiritusind., 1920, 43, 90—91, 104, 111—112.

THE rapid darkening which occurs in the juice of sliced or pulped potatoes is mainly due to the formation of melanin by the action of tyrosinase on tyrosine. A summary of the literature of the subject is given. The darkening is much more pronounced with some kinds of potatoes than with others. It may be expressed quantitatively by the melanin-number determined as follows:—5lb. of potatoes is washed, peeled, and pulped, and the juice is separated by a hand-press and freed from suspended matter and starch granules by centrifuging. About 1 hour after pulping the juice is slightly acidified with acetic acid, heated to boiling, and filtered from coagulated proteins. Ten c.c. is diluted to 100 c.c., and 10 c.c. of the diluted juice is treated with 1 c.c. of 10% sulphuric acid and oxidised in the warm with N/500 permanganate solution until decolorised. The number of c.c. of the permanganate solution required to decolorise 10 c.c. of the diluted juice is the melanin-number of the fresh juice. If the fresh juice is treated with 0.3% of sodium fluoride and left to stand for 24 hours the proportion of amino-acid nitrogen present increases owing to autolysis, and the melanin-number is increased.

The difference between the melanin-numbers before and after this 24 hours' autolysis is designated the autolytic value. For 16 different strains of potatoes tested the melanin-numbers of the fresh juices ranged from 5.8 to 17.5, and of the autolysed juices from 8.7 to 21.3, the autolytic values ranging from 1.6 to 13.1. After storage for 6 months potatoes show much higher autolytic values; the proportion of amino-acids increases during storage, whilst that of tyrosinase diminishes. If the fresh juice is rendered slightly alkaline before the 24 hours' autolysis, the melanin-number found after autolysis is appreciably higher than when the reaction of the juice remains acid, especially in the case of potatoes which have been stored.—J. H. L.

Foodstuffs; Estimation of water in —. K. Scheringa. Pharm. Weekblad, 1920, 57, 398—403.

TESTS made with meal (potato, wheat, and bone), milk powder, apples, carrots, jam, bread, cheese, etc., showed, in certain cases, slightly higher results when the water was determined by drying at 110° or 120° C. than when it was determined by distillation with xylol (b.p. up to 140° C.).—W. J. W.

Vitamine; Water-soluble — in milk. T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1920, 41, 515—523.

THE authors claim that larger quantities of milk (16 c.c. per day) are necessary to supply the vitamins for the growth of rats than was found by Hopkins (J. Physiol., 1912, 44, 425).—J. C. D.

Vitamine; Fat-soluble — in plant tissues. T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1920, 41, 549—565.

THE value of certain dried vegetables as sources of fat-soluble A is as high as that of butter-fat. Thus normal growth in rats may be obtained when the A vitamin is supplied in the form of 0.1 g. of dried tomato daily. The liability of fat-soluble A to destruction by heat reported by Steenbock and others (J., 1918, 712 A) and Drummond (J., 1919, 435 A) is not confirmed.—J. C. D.

Fruit juices; Antiscorbutic properties of concentrated —. A. Harden and R. Robison. Biochem. J., 1920, 14, 171—177.

ORANGE juice may be concentrated to dryness by a vacuum process at low temperature without any appreciable reduction in its antiscorbutic property. This method might be employed commercially for the preparation of a stable product containing a high concentration of the antiscorbutic vitamin. —J. C. D.

Vegetable and fruit juices; Effect of heat on antiscorbutic value of —. E. M. Delf. Biochem. J., 1920, 14, 211—228.

THE destruction of the antiscorbutic accessory factor by heat is not so rapid as was previously believed. Autoclaving the juice of cabbages, swedes, and oranges at temperatures up to 130° C. causes a corresponding loss of the vitamin, but in the case of orange juice it is not serious. The stability of the antiscorbutic factor in orange juice is remarkable, and does not appear to be entirely due to the presence of a high percentage of free acid. It is probable that destruction of the antiscorbutic property of fruit and vegetable juices by heat is much less when air or oxygen is absent. These observations have an important bearing upon the processes employed in the preservation of fruit and vegetables.—J. C. D.

Vegetables; Losses incurred in cooking of —. II. Green vegetables. H. Masters and P. Garbutt. Biochem. J., 1920, 14, 75—90.

THE addition of a small quantity of alkali to the

water employed in cooking green vegetables has not only a marked effect upon the colour, but also decreases both the time required for cooking and the losses incurred. No such effects were observed when salt was added. The addition of a small amount of ammonium carbonate to the water employed for steaming vegetables has a beneficial influence on the colour.—J. C. D.

Caffeine in mixtures of coffee and coffee substitutes and in caffeine-free coffee; Determination of —. E. Vautier. Mitt. Lebensmittelunters. u. Hyg., 1919, 10, 273–277. Chem. Zentr., 1920, 91, II., 414.

THE method previously described (J., 1918, 712 A) is not applicable when the amount of caffeine present is very small. In such cases it is advisable to decompose the crude caffeine obtained by ethereal extraction, by Kjeldahl's method (1 c.c. of N/10 acid=0.00485 g. of anhydrous or 0.00530 g. of hydrated caffeine). If necessary the crude caffeine may first be partially or completely purified, e.g., after removal of fats (*loc. cit.*) its aqueous solution is treated with 0.1–0.2 g. of sodium carbonate to fix the humic acids, and after evaporation and complete drying the caffeine is extracted in the pure state by chloroform.—J. H. L.

Oil cakes and the like; Process and apparatus for adapting — for human food. K. Erslev, Nijmegen. E.P. 128,216, 11.6.19. (Appl. 14,729/19.) Conv., 1.8.17.

FINELY-GROUND, dried oil cake or the like is extracted with a fat solvent, the residue is ground, dried and extracted with absolute alcohol. The solvents are recovered for further use by distillation, and fats, carbohydrates, lecithin, etc., may be recovered from the extracts. The extractions are carried out by treating the material with a counter-current of the solvent, and two types of suitable apparatus are described.—L. A. C.

Cellulosic material; Transformation of — into easily digestible fodder. F. Lehmann, Göttingen. G.P. 307,616, 16.7.16.

AFTER the material has been decomposed by heating with alkalis, a part of the cellulose is oxidised to acids for the purpose of neutralising the alkali. Oxidation may be effected by means of air or oxidising agents such as sodium peroxide or potassium nitrate, and oxygen-carriers such as iron or manganese salts may be used. Palatable fodder is thus produced even when 8–10% of soda is used.—J. H. L.

Cellulosic plant materials; Production of foodstuffs or fodder from —. P. Strahl, Berlin. G.P. 317,111, 20.7.17.

AFTER the material, e.g., straw, husks, etc., has been decomposed by alkali hydroxides, alkaline earths, or mixtures thereof, the alkali is neutralised by addition of a vegetable or amylaceous material or juice which has been subjected to lactic fermentation.—J. H. L.

Milk; Preventing the souring of —. R. Marcus, Frankfort. G.P. 317,874, 13.4.17.

MILK is treated with pure, sterilised, inert colloids, such as silicic acid (5–10%), clay or alumina, in the form of powder or lumps.—J. H. L.

Bassia seeds; Manufacture of edible products from — and especially from compressed residues of the same. Halstein-Oelwerke G.m.b.H., Altona. G.P. 318,413, 26.9.16. Addition to 250,144 (U.S.P. 1,030,674, and E.P. 23,595 of 1911; J., 1912, 697, 1092).

THE comminuted seeds or pressed cake, mixed with water and slightly acidified, are heated, if necessary under pressure, to decompose and precipitate the sapotoxins and bitter substances and saccharify the starch. The material is then dried and extracted, first with dilute cold alcohol and then with strong warm alcohol. After the heating the liquid may be separated from the solid residue, and converted into syrup, caramel, or coffee substitute, whilst the residue, extracted as described above, can be used as fodder. The process can be applied also to horse-chestnuts, acorns, beans, etc.—J. H. L.

XIXB.—WATER PURIFICATION; SANITATION.

Boiler-feed water; Substitutes for sodium carbonate for softening —. C. Braungard. Chem.-Zeit., 1920, 44, 334–335.

THE procedure to be adopted when using sodium or potassium hydroxide, potassium carbonate, or barium hydroxide as substitutes for sodium carbonate in the treatment of various types of boiler-feed water is described.—C. A. M.

Clay suspensions and silicic acid; Coagulation of —. O. M. Smith. J. Amer. Chem. Soc., 1920, 42, 460–472.

MANY natural surface waters in the Mississippi valley contain colloidal clay and silicic acid, and experiments were made on the precipitation of such colloidal solutions and suspensions. Silicic acid is not precipitated, from a solution containing 184 pts. SiO_2 per million, by 0.07N concentration of various alkali salts, magnesium bicarbonate and sulphate, barium, calcium, ferric and aluminium chlorides, aluminium, ferrous and ammonium sulphates, but is precipitated by sodium hydroxide 0.099N, calcium hydroxide and barium hydroxide 0.0019N, and colloidal iron 0.0045N. For the precipitation of silicic acid by alkali in the presence of aluminium salts the optimum hydrogen ion concentration is 1×10^{-4} . If the alkali is added all at once, the silicic acid prevents the precipitation of aluminium hydroxide, apparently by acting as a protective colloid. The presence of divalent cations destroys this protective power. For the coagulation of clay suspensions, the order of efficiency of the electrolytes examined was: aluminium sulphate, calcium and barium hydroxides, calcium chloride, magnesium sulphate, magnesium and calcium bicarbonates. The aluminium cation is 5 times as effective as the calcium or barium ion. Sodium hydroxide, carbonate, and sulphate at first retard coagulation when aluminium sulphate is added to a clay suspension. As the quantity of aluminium sulphate is increased, there is at first increased dispersion, then coagulation, followed by renewed dispersion and a final coagulation. The presence of silicic acid has in all cases, whatever salts may be present, a retarding influence on the coagulation of clay suspensions.—E. H. R.

Sewage purified by the activated sludge process; Action of the bacteria of — on proteins, urea, and nitrates. P. Courmont and A. Rochemaix. Comptes rend., 1920, 470, 967–970.

THE proteolytic properties of the seven species of bacteria found in the effluent from sewage purified by the activated sludge process are either absent or very reduced. Only with *B. subtilis* was any positive result obtained. Three out of the seven species ferment urea; *B. subtilis* exerts a slight action, and

the other three are without action on urea. Five out of the seven species are direct denitrifying agents as shown by their action on potassium nitrate.—W. G.

[*Sewage*] *sludges; Action of activated*. — F. Diéner, F. Wandenbulke, and M. Launey. Comptes rend., 1920, 170, 1089–1092.

By varying the amount of activated sludge used it was found that the ratio of ammonia destroyed to the dry weight of sludge introduced diminishes as the amount of sludge used increases. This process of purification rapidly yields an effluent free from ammonia and putrefactive matter, but the reduction of the number of germs is apparently very variable.—W. G.

Sterilising power of acids. E. Aubel. Comptes rend., 1920, 170, 970–972.

A comparison of the action of certain organic and inorganic acids on the pyrocyanic bacillus shows no preponderating influence of the cations. The nature of the acids seems to play an important part. The organic acids used (formic, acetic, oxalic, tartaric, lactic) show increased toxicity with decrease in molecular weight and were more active than the inorganic acids (sulphuric, phosphoric, hydrochloric, nitric). Sulphuric acid apparently has some specific action.—W. G.

Carbon monoxide; Removal of — from air. A. B. Lamb, W. C. Bray, and J. C. W. Frazer. J. Ind. Eng. Chem., 1920, 12, 213–221.

Of many substances (ozone, palladium, mercuric oxide and chromic acid, silver oxide, silver permanganate, copper oxide and cobalt oxide, etc.) examined as absorbents or catalytic oxidisers of carbon monoxide, the best consisted of a mixture of manganese dioxide, 50, copper oxide, 30, cobalt oxide (Co_2O_3), 15, and silver oxide, 5%; this mixture is known as "Hopcalite I." The manganese dioxide was prepared by the action of manganese sulphate on potassium permanganate in sulphuric acid solution; the silver oxide was precipitated in the mixed sludge of the other oxides. After washing, the whole mixture was collected on a filter, kneaded, dried, and ground. The granular mixture thus obtained removes more than 90% of carbon monoxide from a 0.25% carbon monoxide-air mixture at ordinary temperature; it appears to act for an indefinite period when the air is dry. For practical use in gas-mask canisters it is necessary to provide a preliminary calcium chloride drying chamber; the "life" of the absorbent then depends on that of the drier.—W. P. S.

Charcoal; Behaviour of — with respect to chlorine. G. S. Bohart and E. Q. Adams. J. Amer. Chem. Soc., 1920, 42, 523–544.

Two processes take place during the passage of chlorine through charcoal, viz., absorption or adsorption, which cannot be distinguished, and catalytic formation of hydrochloric acid. According to the conditions, chlorine or hydrochloric acid may first appear in the emerging gas when the charcoal has become saturated; the period during which the transmitted gases are free from either is called the service time of the charcoal. The service times of different charcoals could not be correlated with their apparent densities. For any one charcoal the service time increases more rapidly than the depth of the absorbing layer. Charcoals with the greatest chlorine capacity have the greatest catalytic activity for the formation of hydrochloric acid. The proportion of hydrochloric acid formed increases with increasing moisture content of the gases, but the service time of the charcoal passes through a minimum, in the case of a gas stream containing air and chlorine in the ratio 500:1, when the gases are 50% saturated. Below 12.5° C. chlorine appears

first in the transmitted gases; above this temperature hydrochloric acid. The service time is at a minimum between 0° and 12.5° C. Reduction of pressure has little or no effect. Exposure to chlorine followed by heating to redness increases the chlorine capacity of charcoal.—E. H. R.

Chloropicrin and carbon tetrachloride; Velocity of adsorption of — by charcoal. H. S. Harned. J. Amer. Chem. Soc., 1920, 42, 372–391.

The velocity of adsorption was measured by exposing a known weight of charcoal to the vapour, at low pressure, for a definite time, and determining the amount adsorbed by the increase in weight of the charcoal. To obtain reproducible results it was necessary to heat the charcoal in a vacuum to 700° C., cool in a vacuum, expose to the vapour under examination and again heat to 700° C. in a high vacuum. With charcoal thus treated the adsorption velocity is a maximum, and the results are expressed by the equation $m = 1/t \log A/(A - K)$, where K is the amount adsorbed per gram of charcoal in time t , A is the amount adsorbed when t is infinitely long, and m is a constant.—E. H. R.

Mustard gas; Minimum effective concentration of —. C. I. Reed. J. Pharm. Exp. Ther., 1920, 15, 77–80.

MUSTARD gas at a concentration of 0.0005 mg. per litre will produce definite reaction in the human eye in less than an hour's exposure.—J. C. D.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; Determination of the alkaloids of the pharmacopœia with special reference to the estimation of — in opium and its preparations. Rapp. Apoth.-Zeit., 1920, 35, 17–20. Chem. Zentr., 1920, 91, 11., 392.

The method previously described (J., 1919, 336 A) is applicable to the determination of morphine in opium etc., and especially to the determination of small quantities of morphine alone or in presence of narcotine if the latter be first removed by extracting an acetic acid solution with chloroform.

—G. F. M.

Pituitary gland; Pressor compound in —. A. C. Crawford. J. Pharm. Exp. Ther., 1920, 15, 81–91.

By treating extracts of the posterior lobe of the pituitary with mercuric chloride a substance is precipitated which possesses powerful pressor effect. The product appears to be pure, but no crystalline salts or derivatives have been obtained. The yield was very small.—J. C. D.

p-Ureidophenylacetylurea and related compounds; Preparation of —. M. Rising. J. Amer. Chem. Soc., 1920, 42, 128–136.

The preparation of *p*-ureidophenylacetylurea, the first of a series of ureido-phenylacetyl derivatives of urea which are to be investigated with regard to physiological activity, particularly as hypnotics, is described. *p*-Nitrophenylacetyl chloride is condensed with urea in boiling benzene solution to yield *p*-nitrophenylacetylurea; the latter is quantitatively reduced by a solution of stannous chloride in cold glacial acetic acid to *p*-aminophenylacetylurea, which decomposes without melting at 192°–193° C. When the hydrochloride of the latter is treated with potassium cyanate *p*-ureidophenylacetylurea, $\text{NH}_2\text{CO.NH.C}_6\text{H}_4\text{CH}_2\text{CO.NH.CO.NH}_2$, is produced. (Cf. J.C.S., 1., 387.)—H. W.

Cyanamide and its derivatives; Action of chlorine, of hypochlorous acid, and of cyanogen chloride on —. C. Mauguin and L. J. Simon. Comptes rend., 1920, 170, 998–1001.

CYANAMIDE undergoes marked polymerisation when chlorine is passed over it. When the gas is passed into an aqueous solution of the amide or its calcium salt an extremely unstable, lachrymatory product results. When cyanamide, in aqueous solution is added gradually to an aqueous solution of hypochlorous acid free from chlorine and the mixture cooled to 0° C., a very unstable crystalline product, dangerous to handle, separates out. When perfectly dry silver cyanamide is added to an excess of cyanogen chloride at 0° C., a silver compound, AgN(CN)_2 , is obtained as a white powder, which is decomposed by hydrogen chloride in ethereal solution giving dicyanoimide hydrochloride, and in water by dilute hydrochloric acid to give cyanourea.—W. G.

Benzoic acid; Purification of — by fractional condensation. M. Phillips and H. D. Gibbs. J. Ind. Eng. Chem., 1920, 12, 277–279.

Crude benzoic acid is vaporised in a cylindrical iron vessel, the vapour escaping at the top through a 1 in. iron pipe, which extends through two sheets of asbestos and a thick glass plate placed horizontally just above the cylinder into a circular wire-gauze (½ in. mesh) chamber resting on the glass plate; other wire gauze chambers are fitted concentrically round the first and the series is covered with

a second glass plate. The cylinder is heated by an oil bath, and the chambers by a current of hot air. When the temperature inside the first wire-gauze chamber is about 60° C., and that of the oil-bath 120° C. the air inflow into the chambers is discontinued and air is passed into the top of the cylinder through a copper coil in the oil bath. The benzoic acid sublimes and condenses on the gauze screens. There is a sharp drop in temperature as the gases pass through the screens and very pure benzoic acid may be obtained in one or other of the chambers.

—W. P. S.

Chlorobenzenes; Analysis by distillation of industrial —. F. Bourion. Comptes rend., 1920, 170, 933–935.

From 1500 to 1800 g. of the crude chlorobenzene is divided by distillation into three fractions of b.p. 80°–130° C., 130°–131.5° C., and 131.5°–172° C. respectively. The first fraction (benzene plus monochlorobenzene) is further fractionated, using a Vigreux column, into six fractions, the b.p. and benzene content of which are as follows: b.p. 81°–90° C., 98% C_6H_6 ; 90°–100° C., 90%; 100°–110° C., 50%; 110°–120° C., 20%; 120°–128° C., 10%; 128°–130° C., 2% C_6H_6 . The portion b.p. 131.5°–172° C. (monochlorobenzene and polychlorobenzenes) is also fractionated, giving the following fraction: b.p., 131.5°–134° C., 98% $\text{C}_6\text{H}_5\text{Cl}$; 134°–140° C., 90%; 140°–150° C., 60%; 150°–160° C., 10%; 160°–165° C., 2% $\text{C}_6\text{H}_2\text{Cl}_2$. The fraction b.p., 130°–131.5° C. is not pure monochlorobenzene, and an aliquot portion of it is redistilled to determine its content of polychlorobenzenes.—W. G.

Chlorobenzenes; Physico-chemical method of analysis of industrial —. F. Bourion. Comptes rend., 1920, 170, 990–993.

A SIMPLER, and much more rapid, though somewhat less exact, process than the method previously described (preceding abstract) is to divide the known weight of the chlorobenzene into two fractions, the first distilling below 130° C. consisting of benzene and chlorobenzene, the second not passing over at 130° C. consisting of chlorobenzene and *p*-dichlorobenzene. The densities of these two fractions are determined, and from these results and the known densities of benzene, chlorobenzene, and *p*-dichlorobenzene, the relative amounts of the two ingredients in each fraction can be calculated and hence the purity of the original sample determined. The method gives results for benzene accurate to 5% of the actual amount present, but for the polychlorobenzenes, if present, the result is only accurate to 6–24% of the amount actually present.

—W. G.

Acrolein; New reaction of —. L. Tsalapatanis. Anal. Soc. Quim. Argentina, 1917, 5, 241–245.

THE liquid to be tested is heated with 1–2 c.c. of an aqueous solution of resorcinol and a few drops of 10% caustic soda solution. After 2 mins. a bluish-green coloration appears in dilute, and a red one in concentrated, solutions. The reaction is extremely sensitive. The colour, which is very stable, is destroyed by acids, but restored by caustic soda.

—W. R. S.

Fatty acids; Catalytic decomposition of — by carbon. J. B. Senderens and J. Aboulenc. Comptes rend., 1920, 170, 1061–1067.

ACETIC acid and its homologues are decomposed when passed over animal charcoal at 360°–380° C., giving carbon dioxide, ethylenic hydrocarbons, carbon monoxide, paraffin hydrocarbons, and hydrogen, together with water and small amounts of ketones and aldehydes. With carbon from sugar as the catalyst a considerably higher temperature is necessary, but the products are similar.—W. G.

Distillation apparatus for separation of water [from organic solvents]. G. W. Walker. Chem. News, 1920, 120, 222—223.

WATER may be removed from liquids such as chloroform, benzene, etc., by distillation from a flask provided with two side tubes on its neck. The liquid is boiled until all the water has been expelled through the lower of these side tubes; this tube is then sealed, and the remainder of the dry liquid distilled through the upper side tube, which is connected to a condenser.—W. P. S.

Hyoscyamine; Isolation of —. Chem. Fabr., vorm. Sandoz. E.P. 131,283, 28.7.19. (Appl. 18,686/19.) Conv., 15.8.18.

The powdered leaves, seeds, or roots of *Atropa belladonna*, L., *Hyoscyamus niger*, L., *Datura stramonium*, L., or other solanaceous material, are treated with a dilute solution of a mineral or organic acid, or an acid salt such as aluminium, ferrous, or copper sulphate, or ferric chloride, and the acid mixture is extracted with a fat solvent such as ether, benzene, or the like, containing from 1 to 7% of alcohol. The residue is suspended in a further quantity of a fat solvent and made alkaline by the addition of ammonia or other alkali; after separation of the insoluble matter the extract is concentrated under reduced pressure. Hyoscyamine separates from the solution on standing as long white needles of m. pt. 107°—108° C., $[\alpha]_D = -20.5^\circ$ to -21.3° .—L. A. C.

Glyoxal; Preparation of —. E. C. R. Marks. From A. Bosshard, Zurich. E.P. 140,478, 11.10.17. (Appl. 14,731/17.)

GLYOXAL is formed by the action of ozone on acetylene when the reaction occurs in the presence of a large excess of oxygen, air, or other indifferent gas. Suitable proportions are 1—2% of ozone, 3—4% of acetylene, and 94—96% of air. The process is facilitated by the presence of water vapour or a fine spray of water, whereby the glyoxal is washed out of the gaseous mixture and separates as a concentrated solution.—G. F. M.

Denatured alcohol; Production of —. P. V. H. Pascal, Lille. E.P. 140,527, 3.1.19. (Appl. 224/19.) Conv., 16.1.18. Addition to 140,115.

IN the manufacture of alcohol by the electrolytic hydrogenation of aldehyde or its polymers in an acid bath (J., 1920, 385A), the temperature of the bath is raised slowly to 70°—80° C., whereby reduction and polymerisation products of crotonic aldehyde are formed, which act as denaturants.—L. A. C.

Pyrogallol acid; Preparation of —. E. C. R. Marks. From Nitritfabrik A.-G., Koepenick. E.P. 140,694, 29.8.19. (Appl. 21,281/19.)

PYROGALLOL is obtained in nearly theoretical yield by heating solutions or suspensions of tannin or gallic acid, at temperatures preferably above 160° C., in an autoclave, with a proportion of alkali, alkaline-earth, etc., carbonates or hydroxides not materially exceeding twice the amount required

to effect substitution of the hydrogen atoms of the carboxyl groups initially present, and those formed by hydrolysis (if any).—G. F. M.

Chlorhydrins; Manufacture of —. R. Haddan. From The Commercial Research Co., Long Island City. E.P. 140,831, 27.2.17. (Appl. 2916/17.)

STEAM and oil gas are blown into the anode chamber of a cell for the electrolytic decomposition of sodium chloride solution; the electrolyte is maintained at 95°—100° C., escaping gases from the anode chamber are condensed and the dilute hydrochloric acid obtained is returned to the cell, thereby lowering the voltage necessary for operation. Alternatively an olefine may be mixed with the sodium chloride solution in the anode chamber by agitation, portions of the electrolyte then being removed from time to time from the cell, and the chlorhydrin separated by steam distillation.—L. A. C.

Alkamine esters of alkoxy-aminobenzoic acids and other similar compounds of said acids. Alkamine esters of amino-toluic acids and other similar compounds of said acids. E. A. Wildman, Assignor to Parke, Davis, and Co. U.S.P. (A) 1,317,250 and (B) 1,317,251, 30.9.19. Appl., 29.7.18.

ALKAMINE esters of disubstituted benzoic acids in which the substituents (A) NH_2 and OR (R=alkyl) or (B) NH_2 and CH_3 may occupy any positions in the benzene ring are of value as local anaesthetics. Examples. (A) *m*-Amino-anisoyldiethylaminoethanol, $\text{NH}_2(\text{CH}_2\text{O})\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{O}(\text{CH}_2)_2\cdot\text{N}(\text{C}_2\text{H}_5)_2$ (m.p. of hydrochloride, 160° C.) is prepared by interaction of *m*-nitro-anisoyl chloride and diethylaminoethanol, and reduction of the resulting nitro-compound. (B) The diethylaminoethanol esters of *o*-amino-*p*-toluic acid and *p*-amino-*o*-toluic acid are prepared in a similar manner from diethylaminoethanol and *o*-nitro-*p*-toluoyl chloride or *p*-nitro-*o*-toluoyl chloride. The hydrochlorides melt at 157°—158° C. and 139°—140° C. respectively.

Methane; Oxidation of — [to formaldehyde]. R. K. Bailey, Lawrence. U.S.P. 1,319,748, 28.10.19. Appl., 13.5.15.

METHANE is heated with a substance containing at least a considerable proportion of combined oxygen and nitrogen (e.g., higher oxides of nitrogen or a mixture of nitric oxide and air or oxygen); the mixture is then cooled and certain of the products (higher oxides of nitrogen) are simultaneously neutralised by means of a suspension or sludge of calcium carbonate or the like. After filtering the sludge, formaldehyde may be recovered from the filtrate by distillation.—L. A. C.

Acetic acid; Preparation of — from acetaldehyde and oxygen. Verein für Chem.-Ind. in Mainz, Frankfurt. G.P. 301,274, 4.6.11.

BEFORE oxidation the volatility of the aldehyde is reduced by admixture with an inert diluent such as tetrachloroethane. The oxidation is carried out at 70°—90° C., using air or oxygen at 1—2 atm. pressure, either with or without a catalyst, the acetic acid being finally separated by fractional distillation.—G. F. M.

Pinacone; Preparation of —. Farbenfabr. vorm. F. Bayer und Co. G.P. 306,304, 6.5.17.

IN the electrolytic reduction of acetone in acid solution, the formation of more highly reduced products, such as isopropyl alcohol, is repressed by the addition of metallic salts such as those of bismuth, mercury, manganese, nickel, antimony, silver, and iron.—G. F. M.

Pinacone chlorhydrin; Preparation of —. Farbenfabr. vorm. F. Bayer und Co. G.P. 317,635, 2.9.16.

PINACONE chlorhydrin is obtained by the action of

hydrogen chloride on pinacone at temperatures above that of the formation of the addition product and below that at which pinacoline is formed. At 35°—15° C. the chlorhydrin is formed in quantitative yield, and it may likewise be obtained by heating the hydrogen chloride addition product to that temperature.—G. F. M.

Diarylurethanes; Preparation of —. Chem. Fabr. vorm. Weiler-ter Meer, Uerdingen. G.P. 308,316, 8.4.17.

DIARYLURETHANES are obtained by the interaction, either with or without a diluent, of 1 mol. of a diarylamine or a diarylamine hydrochloride and 1 or more mols. of chloroformic ester, the reaction being accompanied by the evolution of hydrogen chloride.—G. F. M.

Acetaldehyde from acetylene; Preparation of —. Konsort. für Elektrochem. Ind. G.m.b.H., Nuremberg. G.P. (A) 309,103, 19.5.16, and (U) 309,104, 18.10.16.

(A) IN the preparation of acetaldehyde from acetylene by means of acid mercury salt solutions a ferrous salt is added to the reagent, and in order to remove the aldehyde continuously as soon as it is formed, an excess of acetylene is circulated through the catalytic solution, and the unabsorbed excess of the gas, with the addition of an amount of fresh gas corresponding to that absorbed, is re-circulated through the liquid. The formation of condensation products of acetaldehyde is thereby hindered and the acetylene absorption accelerated. (B) The acid solution of a mercury salt containing an iron salt is used at a temperature below its boiling point, and has a sulphuric acid content of 6—35%. By careful regulation of the stream of acetylene it is possible to arrange matters so that the unabsorbed gas carries away the surplus heat of the reaction.—G. F. M.

Aluminium-casein compounds; Preparation of water-soluble —. J. A. Wülfing, Berlin. G.P. 312,702, 20.1.18. Addition to 312,222 (J., 1919, 925 A).

CASEIN is allowed to react with equimolecular quantities of caustic soda and aluminium hydroxide in concentrated aqueous solution. The solution of the soda-alumina-casein compound so obtained is fluid when hot, and sets to a jelly on cooling. It has a limited miscibility with alcohol. Ether precipitates the product from its aqueous alcoholic solution.—A. J. H.

Desoxycholic acid; Preparation of compounds of —. H. Wieland, Munich. G.P. 317,211, 11.2.16. (Cf. U.S.P. 1,252,212; J., 1918, 108 A.)

ADDITION products of desoxycholic acid with hydrocarbons, or other organic compounds, are produced by dissolving the components in a hot solvent, or by dissolving the desoxycholic acid in the other component in a molten state, allowing to crystallise, and washing away the excess by means of a suitable solvent. These addition compounds, being analogous to the choleic acid of the bile, which is an addition product of desoxycholic acid and a fatty acid in the proportion of 8 mols. to 1 mol., are accordingly designated in general as choleic acids. Specially mentioned are stearincholeic acid, m.p. 186° C.; naphthalenecholeic acid (1 mol. naphthalene+3 mols. desoxycholic acid), m.p. 182° C.; phenolcholeic acid, an odourless substance giving a slightly soluble barium and calcium salt; and benzaldehydecholeic acid, m.p. 186° C., from 3 mols. of desoxycholic acid and 1 mol. of benzaldehyde.—G. F. M.

Silver salts; Manufacture of therapeutic agents containing —. Sächsisches Serumwerk und Institut für Bakteriotherapie, Dresden. G.P. 317,509, 12.9.17.

By dissolving silver salts in a considerable excess

of bile, the caustic effects even of concentrated solutions are very much diminished owing to the colloidal nature of the bile. The penetrating and disinfecting powers of the silver salts are increased.—D. W.

Ether; Preparation of —. Elektrizitätswerk Louza, Basle. G.P. 317,559, 29.10.18.

MIXTURES of alcohol and ether containing up to 15% of the latter are obtained by the catalytic reduction of acetaldehyde with hydrogen with the absolute exclusion of oxygen. If only a few tenths per cent. of oxygen is present the ether formation falls off practically to nil. The reaction temperature must be maintained between 90° and 170° C.; at lower temperatures no ether is formed, and above 170° C. the aldehyde commences to decompose.—G. F. M.

Amino-sulphonic acids; Preparation of —. W. Traube, Berlin. G.P. 317,668, 4.7.16.

AMINOSULPHONIC acids are obtained by the action of fluorosulphonic acid or its salts on the corresponding bases, either direct, or in solution in water, alcohol or chloroform, etc. (J., 1919, 695 A).—G. F. M.

Mellitic acid; Preparation of —. R. Lorenz and J. Hausmann, Frankfurt. G.P. 318,200, 29.11.17.

MIXTURES of finely divided coal or soot with tar, pressed into rods or plates and then heated in the absence of air, are subjected to anodic oxidation in alkaline electrolytes, such as solutions of alkali hydroxides or carbonates. By employing a diaphragm hydrogen is obtained as a by-product. Finely divided wood charcoal, coke, etc. may be substituted entirely or in part for the soot.—G. F. M.

Fatty or wax-like compounds [adipic acid esters]; Preparation of —. Farbenfabrik. vorm. F. Bayer und Co. G.P. 318,222, 10.8.17.

THE esters of adipic acid and its derivatives or homologues with dihydric alcohols form tallowy or butter-like masses. The glycol ester may be prepared by mixing a solution of ethyleneglycol and pyridine in pinacoline with a similar solution of the dichloride of adipic acid or by the action of ethylene dibromide on potassium adipate. The propyleneglycol ester is similarly obtained from propylene di-iodide and potassium adipate, whilst α -methyladipic acid and ethylene oxide react to give a brownish waxy mass consisting of the glycol ester of methyladipic acid.—G. F. M.

Arsenic compounds, Aromatic —. The Rockefeller Institute for Medical Research, Assignees of W. A. Jacobs, W. H. Brown, M. Heidelberger, and L. Pearce. E.P. 120,382, 3.10.18. (Appl. 16,093/18.) Conv., 3.10.17.

SEE U.S.P. 1,280,120, and 1,280,125 of 1918; J., 1919, 268 A.

Oxidation of benzene. E.P. 122,167. See III.

Diacyanodiamide. G.P. 318,136. See VII.

Emulsifiable solid hydrocarbons. G.P. 308,442. See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic colour process; Theoretical basis of a new direct — by means of coloured substances. P. R. Kögel. Phot. Korr., 1919, 56, 332—337. Chem. Zentr., 1920, 91, II., 511—512.

THE process depends on the fact that only absorbed light is chemically active, so that a coloured enolic

compound which is changed by light into a colourless keto compound is affected only by light complementary to its own colour. The sensitive film, dark brown in colour, consists of a mixture of three enolic substances, yellow, red, and blue; it bleaches right out in white light but leaves the corresponding colour when acted on by coloured light. Sensitizers may be added to the mixed colours, and the pictures may be fixed.—B. V. S.

Auramine as a [photographic] sensitiser. O. Bloch and F. F. Renwick. *Phot. J.*, 1920, 60, 145—146. (See also *J.*, 1919, 926 A.)

AURAMINE, when used by itself, has very slight effect on the colour sensitiveness of silver gelatino-bromide-plates; the effect on gelatino-chloride plates is, however, very marked, a new band of sensitiveness to the light blue being added. In conjunction with dyes of the isocyanine class (e.g., Sensitol Green—German "Pinaverdol") or of the quino-cyanine class (e.g., Sensitol Red—German "Pina-cyanol") there is marked enhancement of the sensitising properties of the latter dyes in regions of the spectrum for which auramine itself does not sensitise at all. The amount of auramine required is much less than is required to produce a definite colour-screening effect. The auramine also restrains the fogging tendencies of the iso-cyanine dyes. Spectrograms are given illustrating the effects obtained.—B. V. S.

Theory of organic [photographic] developers. B. Homolka. *Phot. Korrr.*, 1919, 56, 387—391. *Chem. Zentr.*, 1920, 91, II., 660.

THE loss of developing power by the introduction of a carboxyl group into pyrogallol in the formation of gallic acid is explained by the formation of an anhydride by the carboxyl group and the hydroxyl group in para position to it. Pyrogallolcarboxylic acid and catechol-*o*-carboxylic acid in which such anhydride formation is not possible are both developers.—B. V. S.

Colorimeter. Gamble. See XXIII.

PATENTS.

Photographic films; Hardening — during development. J. H. Christensen, Sölleröd. E.P. 135,477, 14.11.19. (Appl. 28,287/19.) Conv., 20.11.18.

THE hardening effect on the gelatin of developers containing, e.g., pyrogallol, catechol, or quinol, is considerably increased by the addition to the developer of substances which counteract the swelling of the gelatin, such as alcohol, carbonates, silicates, etc. The addition of a restrainer such as bromide or a borate is preferable in order to prolong the time of development. A film in relief is obtained from which the unexposed and unhardened parts may be washed with hot water, and which may be used for various printing processes, including colour transfer processes.—B. V. S.

Coloured photographs or kinematograph films; Producing —. W. Finnigan, London, and R. A. Rodgers, Hove. E.P. 140,349, 7.1.19. (Appl. 28,247/19.)

Two negatives are taken on two plates or films placed face to face, the upper one being an ordinary plate or film and the lower one panchromatic. From these negatives two positives are printed which are coloured blue-green and pink-red respectively and combined in register.—B. V. S.

Brown tone on [photographic] development prints; Process for producing —. C. Schleussner A.-G., Frankfurt. G.P. 318,503, 10.8.18.

LIGHT-FAST brown tones are obtained by bleaching the developed print, before or after fixing, in a

solution of mercuric chloride containing bromide and then treating it with a solution of sodium thio-sulphate containing lead.—B. V. S.

Gradation of photographic negatives and diapositives; Improvement of —. J. Rieder, Berlin-Steglitz. G.P. 318,820, 5.4.19.

THE picture is provided on the film side with a coating of asphalt, caoutchouc, or similar light-sensitive resin, exposed through the support, and the coating developed with alcohol or acetone, etc. The picture is then treated with an intensifying or reducing solution or with a dye solution, the action of such reagents being modified by the variable permeability to aqueous solutions produced by the top coating.—B. V. S.

Pigment [carbon] prints to metal; Process for transfer of — as etching resists for process blocks. Rotophot-A.-G. für graphische Industrie, Berlin. G.P. 318,687, 26.9.15.

A MATT surface is produced on the metal by electrolytic action before transfer of the carbon print; this prevents the formation of blisters.—B. V. S.

Photographic films; Production of — in natural colours. R. Wellesley, Goodmayes, and T. M. Sanders, Sevenoaks. E.P. 140,560, 18.8.19. (Appl. 4053/19.)

XXII.—EXPLOSIVES; MATCHES.

Tetryl; Stability of —. C. L. Knowles. *J. Ind. Eng. Chem.*, 1920, 12, 246—248.

STABILITY tests of tetryl and of mixtures containing it were made in a modification of Obermüller's apparatus (*J.*, 1905, 347). The purity of tetryl is directly proportional to its m.p. Quantitative heat tests are of little value as an indication of the stability. The instability of ordinary tetryl is due to a large extent to the presence of tetranitrophenylmethylnitramine (*m*-nitrotetryl) formed by the nitration of the monomethylaniline in the dimethylaniline used. *m*-Nitrotetryl may be removed from tetryl by boiling with water which converts it into soluble trinitromethylaminophenol, or with sodium carbonate solution, which yields a soluble salt of trinitroresorcinol. Tetryl is slightly hydrolysed by a dilute solution of sodium carbonate forming sodium picrate, which, however, is stable and does not lower the stability of tetryl to any appreciable extent. Hence sodium carbonate is a satisfactory stabilising agent for tetryl.—C. A. M.

Trinitroxylenes; Manufacture of — for use as a substitute for TNT in bursting charges for high explosive shell. J. Marshall. *J. Ind. Eng. Chem.*, 1920, 12, 248—250.

A MIXTURE of 30 to 50 pts. of trinitroxylenes suspended in 70 to 50 pts. of TNT at 100° C. yields a fluid mass which can be cast directly. The castings resemble paraffin wax, have high and uniform density, are not hygroscopic, and do not become oily even when stored at high temperatures. They can be completely detonated with smaller primers of tetryl than can castings of TNT, and better results can be obtained with crude mixtures of the two compounds than with refined products. Trinitroxylenes is best obtained by the nitration of *m*-xylene, the yields being low from *p*-xylene, whilst xylenes rich in *o*-xylene give low yields of a product with low freezing point. A xylene with the following h.pt. specifications gives the best yields and most satisfactory freezing point:—Range, first drop to flask dry, 3° C.; first drop between 137° 2° and 139° 2° C.; flask dry between 138° 5° and 140° 5° C. Trinitroxylenes with a freezing point of 161° 5° C. or higher shows no tendency to agglomerate into

crystals on treatment with hot water, and can be readily neutralised. Coke-oven xylene gives a better trinitroxylene than xylenes from other sources such as water-gas.—C. A. M.

Hexanitrodiphenylamine; Preparation of — and its use as a primer for shell charges. J. Marshall. J. Ind. Eng. Chem., 1920, 12, 336–340.

HEXANITRODIPHENYLAMINE (hexyl) is exceedingly stable and much safer to handle than tetranitromethylaniline (tetryl) or tetranitraniline (TNA). It is somewhat inferior in detonating power to these, but is superior to TNT. It also has the advantage over the latter of simplicity of manufacture, and involves less costs for plant and labour. It is made by the successive nitration of dinitrodiphenylamine and tetranitrodiphenylamine. In the preparation of the former from aniline yields of 90–95% are obtained by the process claimed in U.S. Pat. 1,309,580/19 (J., 1919, 676A). The dinitro compound can be satisfactorily nitrated by adding it at 70° C. to 3.5–1 parts of a mixed acid containing 30 to 45% of nitric acid and 50 to 40% of sulphuric acid and then raising the temperature to 80°–90° C. until the evolution of NO₂ has practically ceased. The charge is then cooled and filtered and is ready for further nitration. It is added to 3.75 parts of an acid mixture containing 60% HNO₃ and 40% H₂SO₄ at 70° C. and the mixture heated for an hour at 90° C., cooled and filtered from the crystalline hexanitrodiphenylamine. Nitration of the dinitro to the hexanitro compound in one stage (Hoffmann and Dame, J., 1919, 555A) yields an amorphous product. Acid is removed from the "hexyl" by flooding the crystalline material with a large volume of water, and then washing it 2 or 3 times for an hour with boiling water; it is finally centrifuged and dried in trays at temperatures up to 80° C.—C. A. M.

Nitrocellulose; Examination of —. A. Schrimpf. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 91–93.

THE results obtained with Bergmann and Junk's stability test (J., 1920, 314A) are tabulated. To determine the explosion temperature, 0.05 g. of dried nitrocellulose is placed in a test-tube, inserted in an oil bath at 100° C., and the temperature of the bath is raised 5° per min. The results obtained with various explosives are given. With stable nitrocellulose a sharper detonation is obtained than with impure samples; in the latter case nitrous fumes are evolved above 140° C., and the explosion is more of the nature of an ignition than a detonation.—W. J. W.

Smokeless powders; Acidity in —. A. Angeli and G. F. Errani. Gazz. Chim. Ital., 1920, 50, i., 139–148.

DIMETHYLAMINOAZOBENZENE has been applied to the investigation of the presence of acid in various smokeless powders (J., 1918, 608A). Microscopical examination of very thin sections of the powders treated with this indicator shows that in some cases the acidity is distributed almost uniformly throughout the mass of the explosive, whereas in others it is localised in isolated regions often with sharply marked outlines. With certain altered nitrocellulose powders, the intact strips were not coloured on immersion in the reagent, but the latter soon assumed a more or less intense pink colour; if, however, the strips were broken or scraped, the fresh surfaces thus made were immediately coloured scarlet by the indicator. The acids occurring at these surfaces were not completely removed by prolonged washing with boiling water, and were almost insoluble in ether and only partially soluble in alcohol. Towards litmus these strips showed an acid reaction, even at their surface. Coloured plates are given showing the different effects obtained.—T. H. P.

Mercury fulminate; Oxalates in —. A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 89–90.

MERCURIC oxalate cannot be determined in mercury fulminate by a mercury estimation on account of the slight difference in the mercury content of the two salts. Mercurous oxalate (81.96% Hg) can be more readily detected. The oxalates may be separated by means of sodium thiosulphate, in which they are insoluble. The brown coloration which occasionally is found in mixtures of mercury fulminate and potassium chlorate after drying may be due to overheating. Traces of oxalates in the fulminate may produce this coloration after exposure to light owing to their decomposition into mercuric oxide. The explosive effect of mercury fulminate is diminished by presence of oxalates. With 1% the lead plate shows a fairly good impression and radial markings, while with 10% no indentation at all is produced.—W. J. W.

PATENTS.

Explosives; Manufacture of —. G. A. Hedberg, Alingsas. U.S.P. 1,335,785, 6.4.20. Appl., 9.9.19.

MEAL of pine-bark or of pine cones is used as an ingredient in explosives.—W. J. W.

Explosive. J. R. Mardick, Assignor to Electro Metallurgical Co., Niagara Falls. U.S.P. 1,335,788, 6.4.20. Appl., 15.12.17.

AN explosive contains a solid nitro-aromatic compound with at least three nitro-groups, an oxidising agent, a plasticising ingredient, and a silicon-containing substance, the proportions of these ingredients being adjusted so as to render the composition plastic.—W. J. W.

Explosive. J. R. Mardick, and F. M. Becket, Assignors to Electro Metallurgical Co. U.S.P. 1,335,789, 6.4.20. Appl., 19.6.18.

AN explosive comprises a nitro-aromatic compound, an oxidising agent, and a magnesium-silicon alloy.—W. J. W.

Explosive, and method of preparing the same. J. R. Mardick, Assignor to Electro Metallurgical Co. U.S.P. 1,335,790, 6.4.20. Appl., 22.8.18.

AN explosive composition consists of an oxidising salt, a metallic reducing agent, a solid nitro-aromatic compound containing at least three nitro-groups, and a gelatinised plasticising ingredient, the amount of nitro-compound being at least equal to that of the reducing agent, and the proportion of plasticising agent being the minimum required to render the composition plastic.—W. J. W.

Nitroglycerin explosive; Desensitised —. A. A. Starring, Kansas City, Assignor to B. Mossman. U.S.P. 1,336,661, 13.4.20. Appl., 30.11.18.

A DESENSITISING agent comprising carbon tetrachloride and an oil miscible with nitroglycerin is added to nitroglycerin explosives.—W. J. W.

Material capable of nitration; Preparation of — from wood cellulose. C. Claessen, Berlin. G.P. 300,069, 29.7.15.

THE dried cellulose pulp is rolled or pressed and the compressed material reduced to a fine state of division by a suitable wood-working machine. A uniform porous substance is obtained which can be nitrated in the usual way.—B. V. S.

Cellulose; Process and apparatus for nitration of —. A. Vajdady, Budapest. G.P. 300,740, 21.10.15. Conv., 24.7.15.

DURING the nitration process the material is kept in motion so as to absorb the acid in a gradual, continuous and uniform manner, and is then pressed

to yield a product containing only 70% of acid. The rotary nitration apparatus, which is mounted on an inclined shaft and gradually diminishes in size towards the top, is provided with spirally-arranged, internal ribs.—W. J. W.

Nitrocellulose powders; Manufacture of —. Chem. Fabr. von Heyden, A.-G., Radebeul. G.P. 302,460, 17.7.17.

As a partial or entire substitute for acetone fural is employed, either alone or mixed with methyl alcohol, ether, benzene, ethyl formate, ethyl acetate, or chloroform.—W. J. W.

Cellulose derivatives [nitrocellulose]; Process for gelatinising —. Elektro-Osmose A.-G., Berlin. G.P. 309,260, 6.6.17.

THE water in moist cellulose derivatives, e.g., nitrocellulose, is replaced by a gelatinising liquid by means of electro-osmosis.—L. A. C.

Granulated explosives; Process for manufacture of compressed charges from —. Fürstlich Plessische Miedziaknitfabrik, Mittel-Laszk. G.P. 304,000, 9.6.17.

By addition of albumin and formaldehyde to explosives they may be granulated and then compressed, the formaldehyde-albumin mixture also serving as a protection against absorption of moisture.—W. J. W.

Ammonium nitrate; Process for the liquefaction of — for explosive charges. Dynamit Akt.-Ges. vorm. A. Nobel und Co., Hamburg. G.P. (A) 305,567, 31.1.17, and (B) 305,568, 8.1.18.

(A) AMMONIUM nitrate (m.p. 152° C.) is mixed with dicyanodiamide (m.p. 205°), a mixture containing 85% of the former becoming fluid at 115° C. The use of the mixture in the preparation of explosives is easier and less dangerous than that of ammonium nitrate alone. (B) Water is used as the liquefying medium. The pouring temperature of a mixture of 66% ammonium nitrate, 10% sodium nitrate, 20% nitrotoluol, and 4% water is about 80° C.—B. V. S.

Ammonium perchlorate explosives; Manufacture of — capable of being cast. Chem. Fabr. von Heyden A.-G. G.P. 317,030, 2.9.17.

AMMONIUM perchlorate is mixed with nitrates of the alkalis, or of nitrogen bases, and alkali salts of fatty acids or amides. An explosive consisting of ammonium perchlorate, 2.5 parts; ammonium nitrate, 1.5 parts; sodium nitrate, 1.8 parts; and acetamide, 1.5 parts; can be cast at 50° C.—W. J. W.

Incendiary composition for flame-projectors. R. Fieldler, Berlin-Halensee. G.P. 310,148, 21.2.18.

AN incendiary composition consists of nitrocellulose dissolved in ether, and converted into a gelatinous mass by addition of carbon bisulphide and a suitable hydrocarbon. Phosphorus or sulphur, alone or in combination with an oxygen carrier, may be added.—W. J. W.

Signal lights and fire balls; Manufacture of — free from metals and shellac. Geka-Werke Offenbach, G. Krebs. G.P. 314,868, 10.11.17.

PITCH is intimately mixed with alkaline-earth nitrates and barium peroxide, after which chloroform, ethyl acetate, acetone, or carbon bisulphide is added, and the mixture compressed to the desired shape. The resulting product after heating, drying, and cooling possesses the requisite hardness and durability, and burns with intense brilliancy and little smoke.—W. J. W.

Sulphur dye. U.S.P. 1,318,022. See IV.

Washing cellulose preparations. G.P. 307,078. See V.

XXIII.—ANALYSIS.

Viscosimeter; The MacMichael torsional —. W. H. Herschel. J. Ind. Eng. Chem., 1920, 12, 282—286.

THE error due to the elongation of the wire in the MacMichael torsional viscosimeter (J., 1915, 1226) is about 1.6% at 80° C. The ratio between the results obtained with this instrument and with Saybolt's viscosimeter decreases with rise in temperature, and the conversion of the degrees into each other is impracticable except for some assumed sp. gr. A formula is given for converting the readings into poises, but it is not possible to calculate the deflection from the dimensions of the viscosimeter. Each instrument should be separately calibrated by means of liquids of known viscosity and of approximately the same density as the liquid to be examined.—C. A. M.

Colorimeter; The Bawtree —. W. Gamble. Phot. J., 1920, 60, 149—151.

A LONG rectangular box is divided longitudinally into equal parts, each part being lined with mirrors. A lamp illuminating both compartments is placed at one end. The box is interrupted in the middle to allow the insertion of shuttered diaphragms in each compartment, that on one side being plain glass and gelatin film, and that on the other side being in three equal parts, red, green, and blue-violet colour-filters. Each diaphragm is provided with a graduated shutter, and the colours are so adjusted that their combination in equal parts is a colour match for the white light. At the other end of the box are two opal reflectors arranged at 45° over the two compartments respectively, and one of them is provided with a centre aperture to enable the other one to be seen through it when viewed from the side of the box. A coloured filter, placed at the diaphragm, or a sample of pigment placed on the opal can be matched and expressed in terms of the three standard colour screens.—B. V. S.

Flask for the fractional distillation of frothing liquids. E. Lenk. Chem.-Zeit., 1920, 44, 330.

THE lower end of a reflux condenser, the inner tube of which is formed into a series of pear-shaped bulbs, is fused on to the neck of a distillation flask at a point opposite to but below the side tubulure of the flask. By means of a three-way cock the air may be exhausted from the condenser or from the receiver attached to the outlet tube of the flask. In the distillation of viscous liquids a vacuum is first created in the condenser, into which the froth rises and is broken against the walls of the bulbs, and when the liquid is boiling quietly the air is exhausted in the other direction and the distillation continued.—C. A. M.

Electrodes; Platinised glass — for electrolytic determinations. G. Meillère. J. Pharm. Chim., 1920, 21, 311—313.

A SOLUTION of platinum chloride in methyl alcohol, to which a small quantity of an essential oil is added, is applied to the surface of the glass, into which has previously been fused a short piece of platinum wire; the glass is then heated until all the organic matter has been burnt. Several successive treatments may be applied in order to obtain a good coating of platinum. If the glass is etched previously with hydrofluoric acid the platinum adheres better and has a more or less matt surface.—W. P. S.

Indicators and their industrial application. H. A. Luhs. J. Ind. Eng. Chem., 1920, 12, 273—274.

IN the precipitation of anthranilic acid from its alkaline solution by the addition of mineral acid, an

acid reaction to methyl-red indicates that the end-point is approached; on further addition of acid the point of maximum precipitation is shown by an acid reaction to thymol-blue. Thymolsulphophthalein is a useful indicator in the "liming" of sulphonation mixtures; a red coloration indicates that free acid is still present. When the indicator shows a yellow colour the end-point is near, whilst a blue colour shows that the mixture is alkaline. Dibromoresulphophthalein or dibromothymolsulphophthalein may be used as substitutes for litmus; the former changes from yellow to purple and the latter from yellow to blue.—W. P. S.

Arc images in chemical analysis. W. R. Mott. Trans. Amer. Electrochem. Soc., 1920, 121—160. [Advance copy.]

An electric arc is arranged to project through a lens an image of the arc on to a screen, a magnification of 20 times being generally employed, though a smaller magnification is necessary for faint arcs; the lower carbon has a small depression drilled in it for reception of about 0.5 gm. of the material under examination; generally the lower carbon is positive. Observations are made as to the behaviour of the substance on melting, formation of a metallic bead or wetting of the carbon, the colour of the flame, smoke formation, odour, nature and sequence of distillation, and especially the nature and colour of the deposits on the electrodes, both hot and cold. Reagents may be added to modify the course of the reaction, such as silica for the formation of characteristic coloured beads with certain metallic oxides, lead as a solvent for gold in the presence of iron, etc. The metals are divided into two main classes, (A) those that do not wet carbon, form molten beads, and give light in the core of the arc stream only, and (B) those that wet and dissolve carbon when melted and give light in both the core and the shell of the arc stream. Generally class A metals are easy to reduce from their oxides and class B difficult. The classes are subdivided into two groups in class A (group I including the metalloids) and seven groups in class B. A long list of distinctive tests is given for 65 elements arranged in groups as above. The delicacy of the tests is greatest where ordinary methods, including spectrum analysis, are least effective, especially as regards the very refractory elements; the amount which can be detected varies from 0.02 mg. for silver, gold, and tungsten to 0.1 mg. for sulphur, phosphorus, cadmium, platinum, chromium, vanadium, titanium, uranium, yttrium, zirconium, thorium, columbium, molybdenum, and tantalum, and about 1 mg. for most of the other elements. In mixtures the delicacy generally decreases about 20%. Separations can be often effected, in some cases an addition with intermediate boiling point assisting the separation. The analysis is mainly qualitative, but semi-quantitative results can often be obtained; e.g., cadmium in zinc can be estimated to within a few per cent., and chromium can be estimated by the amount of colour produced in the barium aluminate test for that metal.—B. V. S.

Chlorine; Determination of — with the nephelometer. A. B. Lamb, P. W. Carleton, and W. B. Meldrum. J. Amer. Chem. Soc., 1920, 42, 251—259.

SILVER chloride was precipitated in 50% alcohol-water solutions of sodium chloride of widely differing concentrations, and the mixtures were heated for 30 mins. at 40° C. after precipitation. In this way a more intense and constant opalescence was produced than could be attained at room temperature. By this method chlorides can be estimated over the concentration range $4-300 \times 10^{-4}N$. The

opalescence of silver chloride in water is 15% greater than in 50% alcohol or 50% acetic acid.

—J. F. S.

Iron [in grape must etc.]; Determination of minute quantities of —. L. Mathieu. Bull. Assoc. Chim. Sucr., 1919, 37, 205—208.

THE ash from 10 c.c. of grape must or a corresponding amount of other material is treated with 5 c.c. of hydrochloric acid (1 in 4), and, without filtration, 10 c.c. of 1% potassium thiocyanate is added. The liquid is made up to 50 c.c., and its colour is matched by adding standard ferric chloride solution to 50 c.c. of a solution containing the same quantities of acid and thiocyanate as the test liquid.

—J. H. L.

Proteins; Use of ethyl acetate as a precipitant for —. A. Marie. Ann. Inst. Pasteur, 1920, 34, 159—161.

ETHYL acetate gives a marked precipitate with even dilute solutions of proteins, and a turbidity with peptones, proteoses, or albumoses. On the other hand, solutions of amino-acids or of vegetable or animal alkaloids show no change on the addition of ethyl acetate.—W. G.

Amino-acids; Determination of — by means of the hydrogen electrode. E. L. Tague. J. Amer. Chem. Soc., 1920, 42, 173—184.

THE neutralisation curves of amino-acids are obtained as follows: Sufficient standard alkali is added to a definite volume of the aqueous solution of the amino-acid to give it a pH value of about 12.5. Then to an equal volume of water the same standard alkali is added to give the same pH value, care being taken to add sufficient water to give the blank the same volume as the original at the pH value compared. By subtracting the number of c.c. used in the blank from that required in the original the number of c.c. of alkali necessary to neutralise the amino-acid alone is obtained.—J. F. S.

Crude fibre [in feeding stuffs etc.]; Condenser for use in the determination of —. C. A. Clemens. J. Ind. Eng. Chem., 1920, 12, 288—289.

A CONDENSER possessing several advantages over the apparatus devised by Spears (J., 1919, 230a) is described.—C. A. M.

PATENTS.

Carbon monoxide; Oxidation of —. K. Hofmann, Charlottenburg. G.P. 307,614, 19.7.16.

THE oxidation of carbon monoxide by chromic acid solutions is much accelerated by the addition of mercuric oxide, and absorption of this gas from air or gaseous mixtures by the reagent is sufficiently rapid for analytical or hygienic purposes.

—G. F. M.

Soda-lime. U.S.P. 1,335,949. See VII.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Beekton. Settling tanks, separators, etc. 13,423. May 15.

Bilsland, Macbeth, and Dunlop Rubber Co. Mixing or grinding mills etc. 14,115 and 14,118. May 21.

Blom. Effecting condensation reactions. 13,055. May 11.

De Wendel. Transport and storage vessels for liquid air or gas. 12,942. May 10. (Ger., 7,11.16.)

Doverdale. Filtering, clarifying, etc. liquids. 14,030. May 21.

Duckham, and Thermal Industrial and Chemical Research Co. Fractional distillation. 14,104. May 21.

Emerson. Apparatus for distillation. 12,922. May 10. (U.S., 8.5.19.)

Krüger and Krüger. Mixing air and liquids. 13,210. May 13.

Morgan, and Thermal Industrial and Chemical Research Co. Recovering gases absorbed by solids. 14,102. May 21.

COMPLETE SPECIFICATIONS ACCEPTED.

8954 (1918). Barbet et Fils et Cie. Heat exchangers for continuous rectification of liquefied gases. (142,519.) May 19.

3851 and 18,742 (1919). Bulgin, Hall, and Searle. Apparatus for treating air or gases with liquids or *vice versa*. (142,941.) May 27.

3985 (1919). Schuck. Production of a catalyst. (142,576.) May 19.

17,817 (1919). Tiesen. Furnaces. (142,710.) May 19.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Duckham, and Woodall, Duckham, and Jones. Gasifying fuel. 12,937 and 13,373. May 10 and 14. Durrant and Wilford. Motor fuel. 13,173. May 12.

Edser. Production of fuel. 14,126. May 21.

Félizat and Guignard. Destructive distillation of shales, schists, etc. 12,951. May 10. (Fr., 12.4.19.)

Hughes. Artificial fuel. 13,882. May 20.

Hutton and Neilson. Acid refining of mineral oils. 13,887-8. May 20.

Lewis and Quain. Purification of gases. 13,554. May 17.

Morgan, and Thermal Industrial and Chemical Research Co. Treatment of acid used for purifying oils etc. 14,103. May 21.

Perry. Apparatus for distilling carbonaceous material. 12,894. May 10.

Rambush. Removal of sulphur from gases. 14,106. May 21.

Sawtelle. Destructive distillation of wood. 13,718. May 18. (U.S., 10.9.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

2661 (1919). La Porta and Bartolomeis. Furnaces for distilling asphalt rock, bituminous shale, etc. (142,541.) May 19.

4154 (1919). Freeman. Gasifying solid and liquid fuels. (142,945.) May 27.

11,178(1919). Marks (U.S. Industrial Alcohol Co.). Liquid fuel. (143,017.) May 27.

14,475 (1919). Groundstroem. Gas retorts. (112,689.) May 19.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Brunner. Manufacture of hydrazobenzene etc. in solid form. 13,592. May 17. (Switz., 12.7.19.)

Morgan. Manufacture of colour-producing intermediates. 13,954. May 20.

Poncelot. Colouring matter. 13,157. May 12. (Fr., 12.5.19.)

COMPLETE SPECIFICATION ACCEPTED.

11,101 (1919). Brassard and Crawford, and Buckle. Manufacture of indophenolic compounds. (143,014.) May 27.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

British Cellulose and Chemical Manuf. Co., and Roy. Apparatus for making threads. 13,796 and 13,926. May 19 and 20.

Bronnert. Manufacture of artificial silk. 12,972, 13,387, 13,586, 14,068. May 10, 14, 17, and 21.

Commin. Manufacture of fibre compositions. 13,869. May 20.

Dreyfus. Manufacture of cellulose derivatives. 13,289 and 13,290. May 13.

Heilbronner. Impregnation of paper etc. 13,084. May 11. (Ger., 12.1.17.)

Lilienfeld. Producing viscous liquids. 13,186. May 12. (Austria, 1.8.19.)

Lilienfeld. Production of cellulose ethers. 13,187. May 12. (Austria, 5.5.20.)

Lilienfeld. Manufacture of alkali cellulose. 13,286. May 13. (Austria, 1.8.19.)

Lilienfeld. Manufacture of plastic masses. 13,350. May 14. (Austria, 1.8.19.)

Lilienfeld. 13,188, 13,287, and 13,568. See XVII.

Pollak (A.-G. Seeriet Bleicherei). Refining and perfecting cotton fabrics. 13,840. May 19.

Thunert. Production of paper. 13,842. May 19. (Ger., 12.7.19.)

COMPLETE SPECIFICATION ACCEPTED.

24,123 (1919). Kron. Obtaining fibre for the manufacture of pasteboard. (135,466.) May 27.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Bayer und Co. Dyeing with acid sulpho amino dyestuffs. 13,161. May 12. (Ger., 31.10.14.)

Kershaw. Bleaching fabrics. 13,731. May 19.

Lord. Apparatus for treating hanks of yarn with liquid. 13,875. May 20.

Sharp. 14,024. See IX.

Soc. Chim. des Usines du Rhône. Dyeing cellulose acetate artificial silk, films, etc. 13,541. May 17. (Fr., 5.9.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

798 (1919). Heymann. Dyeing. (142,899.) May 27.

6362 and 22,202 (1919). Whitaker and Whitaker. Machines for dyeing, scouring, and washing wool, etc. (142,602.) May 19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Asheott. Production of anhydrous magnesium chloride or anhydrous double chlorides of magnesium. 13,061. May 11.
- Craig, Spence, and Spence and Sons. Purification of sulphur. 13,293. May 13.
- Hickman. Fixation of nitrogen. 13,348. May 14.
- Mackay. 12,957. *See X.*
- McKee. Process of making zinc oxide and hydrogen. 13,579. May 17.
- Morgan and others. 14,103. *See II.*
- Nitrogen Corporation. Production of ammonia. 13,810. May 19. (U.S., 23.3.16.)
- Norsk Hydro-Elektrisk Kvaestofaktieselskab. Production of ammonia and formic acid or ammonium formate from barium cyanide. 13,702. May 18. (Norway, 26.5.19.)
- Norsk Hydro-Elektrisk Kvaestofaktieselskab. Producing mixtures of nitrogen and hydrogen. 14,069. May 21. (Norway, 23.5.19.)
- Schweiz. Sodafabrik. Production of caustic soda or soda lye. 13,518. May 17. (Switz., 1.6.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 3311 (1918). Pope and Heycock. Production and utilisation of sulphur dichloride. (142,879.) May 27.
- 20,339 (1918). Audianne. Heat interchangers for gases for use in the contact process of making sulphuric acid. (142,522.) May 19.
- 3508 (1919). Darrasso Frères, and Dupont. Utilising marine algae for making formic, acetic, and butyric acids and for extracting salts of iodine and potash. (123,325.) May 27.
- 14,713 (1919). Blair, Campbell, and McLean, Blair, and Ferguson. Preparing powerful oxidising gases for removing carbon and sulphur deposits in hydrogen manufacture. (143,064.) May 27.
- 32,568 (1919). Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of potassium sulphate. (137,296.) May 27.
- 32,886 (1919). Fredriksstad Elekt. Fabr. *See XI.*

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- Atkinson, and Stein and Atkinson. Glass furnaces. 13,924. May 20.
- Beardmore, and Boulton, Ltd. Potters' stove for making earthenware etc. 13,502. May 17.
- Hailwood. Glass manufacture. 14,028. May 21.
- Jones and Sparkes. Fire-brick. 13,747. May 19.

COMPLETE SPECIFICATIONS ACCEPTED.

- 14,455 (1919). Musiol. Enamels and enamelling. (142,688.) May 19.
- 17,458 (1919). Möhn. Oil-fired furnaces for melting glass etc. (143,091.) May 27.
- 20,386 (1919). British Thomson-Houston Co. (General Electric Co.). Refractory material. (142,721.) May 19.
- 22,261 (1919). White (Fours et Procédés Mathy). Crucible furnaces for glass etc. (143,117.) May 27.
- 24,437 (1919). Wilkinson. Glass-furnaces. (143,125.) May 27.

IX.—BUILDING MATERIALS.

APPLICATIONS.

- Crozier. Manufacture of cementitious articles. 13,808. May 19.
- Sharp. Solution for fireproofing wood, fabrics, etc. 14,024. May 21.
- Wennerström. Manufacture of cement. 13,164. May 12. (Sweden, 10.2.19.)

COMPLETE SPECIFICATION ACCEPTED.

- 5153 (1919). Bravin. Concrete etc. (142,958.) May 27.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Budd and Ledwinka. Annealing metals. 13,899. May 20.
- Coles. Apparatus for electro-deposition of metals. 13,272. May 13.
- Hess and Kirschner. Electroplating. 13,210. May 13. (Austria, 10.10.17.)
- Jones. Fusing and purifying non-ferrous metals etc. 13,870. May 20.
- Kaiser and Obenauer. Hardening-agent for wrought iron, steel, etc. 13,513. May 17. (Ger., 18.1.18.)
- Kroll. Producing alloys containing alkaline-earth metals. 13,849. May 19.
- Langer. Electrolytic separation of metals. 13,775. May 19.
- Mackay. Extraction of tungstic acid from tungsten ores. 12,957. May 10.
- Mining and Metallurgical Processes, Ltd. Blast roasting apparatus etc. 13,958. May 20. (Australia, 9.7.19.)
- Moffat. Treating metallic ores. 13,570. May 17. (U.S., 30.4.18.)
- Walter. Producing alloys containing silicon. 13,830. May 19. (Austria, 28.10.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 11,628-9 (1916). Stahlwerke Lindenberg A.-G. Steel alloys. (103,809 and 103,810.) May 27.
- 18,685 (1918). Hadfield. Refining of steel. (142,885.) May 27.
- 3773 (1919). Turnbull. Cleaning blast-furnace gas. (142,938.) May 27.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Chile Exploration Co. Electrodes. 13,572. May 17. (U.S., 21.1.20.)
- Coles. 13,172. *See X.*
- Fuller, and Fuller's United Electric Works. Galvanic batteries. 13,262. May 13.
- Greenwood and Batley, Leitner, and Wood. Electric accumulators etc. 13,955. May 20.
- Herrmann. Manufacture of micanite. 13,670. May 18. (Fr., 29.9.19.)
- Herrmann. Manufacture of electric insulating materials. 13,671-2. May 18. (Fr., 7 and 8.11.19.)
- Hess and Kirschner. 13,210. *See X.*
- Houston. Storage batteries. 12,868. May 10.
- Langer. 13,775. *See X.*
- Pouchain. Positive accumulator electrodes. 12,939. May 10.
- Pouchain. Primary battery. 12,940. May 10.
- Siemens-Schuckertwerke. High-tension electric depositing plants. 13,694. May 18. (Ger., 31.3.16.)
- Webb. Electrolysers. 13,070. May 11.
- Zubiria y Smith. Electric furnaces. 12,953-4. May 10. (Spain, 21 and 22.5.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,179 and 16,154 (1919). Withers (National Electro-Products, Ltd.). Apparatus for electrolysing liquids. (143,002 and 143,082.) May 27.
- 19,378 (1919). Collins. Electric furnaces. (133,026.) May 19.
- 32,886 (1919). Fredriksstad Elektrokemiske Fabriker Akt. Apparatus for electrolysing metal salt solution. (138,862.) May 27.
- 9997 (1920). Moore. Electric furnaces. (143,176.) May 27.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Lilienfeld. Production of oily bodies of high boiling point. 14,091. May 21. (Austria, 10.5.20.)

Salomonson. Neutralising oils or fats. 13,970. May 20.

Soc. Anon. l'Oxydrique Franç. Catalytic hydrogenation of oils, fats, etc. 13,085. May 11. (Fr., 28,519.)

Wade (Wilson and Co.). Compounding fats and oils. 13,582. May 17.

White. Mechanical digester for obtaining oils and fats by cooling. 13,041. May 11.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

McKee. 13,579. See VII.

Nelson. Manufacture of carbon for pigmental etc. purposes. 14,065. May 21.

Scholz and Tiedemann. Working up linoleum scraps into new linoleum. 13,930. May 20. (Ger., 16,518.)

COMPLETE SPECIFICATION ACCEPTED.

20,577 (1919). Arie. Antifouling paint for ships' bottoms. (131,601.) May 27.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATIONS ACCEPTED.

4242 (1919). Smith (Claessen). Utilising bark shavings from rubber trees and extraction of rubber therefrom. (142,946.) May 27.

13,980 (1919). Neilson. Rubber compounds. (127,821.) May 19.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Broens. Product for leather dressing or tanning, dyeing, and tannery. 13,705. May 18.

Dunham. Making casein solution. 13,561. May 17.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Lilienfeld. Production of ethers of carbohydrates, their conversion products and derivatives. 13,188, 13,287, and 13,658. May 12, 13, and 17. (Austria, 6,819 and 5,520.)

COMPLETE SPECIFICATIONS ACCEPTED.

3508 (1919). Darrasse Frères, and Dupont. See VII.

3509 (1919). Darrasse Frères, and Dupont. Utilising carbohydrate in plants, vegetable offal, and waste products. (123,326.) May 27.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATION.

Fazi. Brewing or preserving beer. 13,177. May 12. (Ital., 22,519.)

COMPLETE SPECIFICATIONS ACCEPTED.

14,046 (1919). Baycr and Jensen. Production of alcohol and yeast from seaweed. (119,030.) May 27.

22,905 (1919). Fazi and Peroni. Malting process. (143,121.) May 27.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Activated Sludge, Ltd., and Coombs. Separating matters suspended in sewage etc. 13,202. May 13.

I.—GENERAL; PLANT; MACHINERY.

"Settling" problems [; Continuous —]. W. A. Deane. Trans. Amer. Electrochem. Soc., 1920, 659—688. [Advance copy.]

THE introduction of the Dorr continuous thickener has resulted in greatly increased application of continuous settling methods. Settling may be divided into clarification, which is directly dependent on the area of the settling vessel and is independent of its height, and thickening, which depends on the volume of the thickening zone. The clarification capacity required may be calculated from the formula, $A = 4(F - D) \cdot (3R - Sp)$, where A represents unit thickener area in sq. ft. per ton of solids per 24 hrs., R the settling rate in ft. per hr., Sp the sp. gr. of the liquid, F the ratio of liquid to solids in the feed, and D the ratio of liquid to solids in the discharge. The thickening capacity is calculated from $V = 4T(G - Sp) \div 3G(S - Sp)$, where V represents the volume in cub. ft. required for thickening per ton of solids per 24 hrs., S the sp. gr. of thickened pulp, Sp the average sp. gr. of solution, G the average sp. gr. of solids in the pulp, and T the period of detention in hrs. The governing factor in clarification is the rate of settling of the finest particles. The content of particles in the colloidal condition may be reduced by modifying the previous mechanical treatment so as to reduce the amount of slimes produced, by modification of any previous chemical treatment in the direction of obtaining a coarser precipitate, and by a preliminary heat treatment of the material. Flocculation of colloidal particles may be brought about by the addition of electrolytes and/or colloids, by the electric current, and by biological action. The addition of a colloid together with an electrolyte that will flocculate it is sometimes useful, e.g., the addition of a little clay together with enough sulphuric acid to flocculate it to waste liquors containing silk gum. The passage of an electric current between electrodes immersed in the suspension caused no flocculation when carbon electrodes were used, but was effective when metal was substituted for the carbon. The growth of bacteria under certain conditions tends to cause clarification, as in the activated sludge sewage process. Raising the temperature in almost all cases improves the settling of the solids. Thickening starts from the bottom of the vessel and extends upwards to the zone where the particles just begin to touch one another. The slow action of the rake in the Dorr thickener tends to increase the density of the sludge by enabling the particles to pack more closely. As thickening proceeds the upward escape of the liquid is retarded but may be facilitated by mechanical means. Endosmose has been applied to thickening pulps, and although still in the experimental stage, offers considerable promise as a practical means of reducing the moisture content of substances, like clays, that are particularly difficult to filter. Flocculation and heating both help settling, but the former, unlike the latter, hinders thickening. A comprehensive bibliography of the subject is given.—W. H. C.

Extraction processes; Numerical relationship between cells and treatments in —. L. F. Hawley. J. Ind. Eng. Chem., 1920, 12, 493—496.

THE relationship between the number of treatments and the number of cells in terms of the time required may be represented by the following formula when the pumping of all the cells in action is done simultaneously $n = b(2c - t) + p(2c - t - 1)$, where n represents the time during which each cell stands idle, c the number of cells, and t the number of treatments in terms of the boiling period, b , and

the pumping period, p . In the case of continuous extraction the formula becomes $n = p(2c - t - 1)$, p here representing the time required for pumping the contents of one cell into the next. When each cell is pumped separately modified formulae are required. The formulae show that simultaneous pumping has little if any advantage over separate pumping. (See J., 1917, 1121.) C. A. M.

Liquefied gases; Construction of containers for the transport of —. F. Bannett, G. Rhein, and B. Kurze. Ann. Physik, 1920, 64, 113—114. Chem. Zentr., 1920, 91, 11, 662—663.

VESSELS of celluloid gave very favourable results with liquefied gases, but cannot be employed on account of the brittleness of the material at low temperatures. Transport containers have been made consisting of two concentric spherical brass vessels, the inner vessel being suspended from the neck of the outer. The neck of the inner vessel is made of manganese steel to lower the conductivity. The inter-wall space is reduced to a few mm. pressure by an oil pump, and the remainder of the gas is absorbed by cooled charcoal. In a 25-l. container of this type, the loss was 1.258 kg. per day. In the case of a nickel container with walls 1.5 mm. thick, soldered with a silver alloy, and evacuated with a rotary Gaede pump, the vessel being heated to remove occluded gases, the heat lost through the metal wall of the neck was specially important; the cool gases streaming from the neck did not influence this loss. Heat insulation can be effected by providing a glass tube, sealed to the metal on both sides by a platinum ring. In the case of large containers a long tube or coil of some badly conducting material may be provided. Good results cannot be obtained, however, with uncoated metallic vessels of iron or nickel on account of radiation losses. The best coating material is silver, which must be applied electrolytically. By silvering on both sides, the heat losses by radiation can be reduced by one-half. The most satisfactory vessels, when used for liquid air, showed a daily loss by evaporation of 4%.—E. H. R.

PATENTS.

Pyramidal surfaces for the purification of liquids, vapours, and gases; Combinations of —. P. H. A. Gaillet. E.P. 133,971, 17.10.19. Conv., 18.10.18.

RECTANGULAR plates bent as shown in the figure are arranged in layers in a tank or containing vessel, being mainly supported by the ridge 5, 6, the ele-

ments of each layer being at right angles to the elements in the layer above or below.—B. M. V.

Filling material for absorption and reaction towers. Pryn and Co. G.P. 317,167, 28.3.18. Addition to 317,166.

THE surface of the filling material described in the chief patent (J., 1920, 321 A) is increased without altering the length or width by bending in the end of the inner tube along a diameter of the tube.

—L. A. C.

Feeding material through a rotating cylinder whilst subjected to roasting, mixing, or similar operations; Means for —. A. Sonsthagen. E.P. 140,880, 17.2.19.

THE material is fed through a rotating drum by two sets of helical blades, one of which is fixed to the interior of the drum and the other to a central shaft. One set of blades causes the material to move forward and the other checks the movement so that the material is well mixed. The two sets of blades may be of the same pitch and rotated at different speeds, or the pitch may be different and the speed the same.—W. H. C.

Chemical treatment and grinding or/and mixing; Method of subjecting material to — and apparatus therefor, also ball-mill and combined grinding or/and mixing and vacuum drying apparatus. F. R. Ablett. E.P. 142,176, 27.1.19.

THE material is allowed to fall (with or without balls or pebbles to assist grinding) down a down-take tube where it is crushed by gravity and returned to the top of the same or another down-take by means of a screw conveyor. The undersize material may be removed by a screen or exhaust fan in the return tube, or the whole material may pass through a series of down- and up-takes, being subjected to vacuum drying or to chemical treatment, washing, and de-watering; in the last case the final screw conveyor is preferably made tapering to squeeze the water out. The whole apparatus may be made acid-proof and when a series of up- and down-takes are used the grinding balls may be returned through a separate race.—B. M. V.

Drying excreta, mucilaginous and other solid matters containing a large proportion of water; Apparatus for —. M. M. Lavarack (Rep. of E. C. Lavarack, dec.). E.P. 141,861, 11.3.19.

THE material is fed into a disintegrator from which it falls on to the surface of the upper of two flues, spaced apart within a casing, and is moved along the surface of the flue by scrapers attached to an endless chain. From the upper flue it drops on to the lower flue and is again moved in the opposite direction, and the dried material falls from the lower flue into a worm conveyor by which it is discharged. The drying is effected by the heat from a number of furnaces, built beneath the upper flue, into which the products of combustion pass first, travelling thence through the lower flue to the stack. Air for the furnaces enters the chamber and, together with the water and other vapours given off from the material, passes through the fire-bars so that any noxious fumes are destroyed.—W. H. C.

Drying or cooling coal, limestone and other substances or materials in granular form; Apparatus for —. A. E. Davis. E.P. 141,873, 11.9.19.

THE material is passed downwards through a chamber having double front and back walls, the hollow spaces being connected to each other by inverted V-shaped bars which extend through the material. The drying medium is introduced into the upper part of the space in the double front or back, so that the hot gas comes into contact with the wettest material first. If it is desired to pass the gas backwards and forwards in a zigzag manner through the material, the bars in the upper part are replaced by tubes.—W. H. C.

Desiccation; Method for —. A. W. Lissauer, W. L. Fleisher, and R. E. Keyes, Assrs. to American Drying Processes, Inc. U.S.P. 1,339,115, 4.5.20. Appl., 27.3.19.

AN air sheet is formed and caused to flow in a curved path having the shape of a parabola, and a current of an atomised substance intersects this

curved path in a direction parallel with the axial plane of the curved path.—A. G.

Dryer; Rotary —. A. O. Hurxthal, Assr. to The Philadelphia Textile Machinery Co. U.S.P. 1,339,260, 4.5.20. Appl., 1.12.19.

AIR is circulated by a fan through a chamber containing heating tubes, to a drying chamber which contains a rotating horizontal perforated cylinder. The cylinder contains curved blades which project inwards and which raise the material to be dried and then allow it to fall. A fixed curved plate surrounds the lower part of the cylinder to retain the material, and a partition is provided in the upper part of the drying chamber to cause the hot air to circulate through the cylinder back to the heating chamber.—W. F. F.

Drying machines; Method of preventing eaking and burning-on of material in —. L. Buszinsky and A. Liebbeit. G.P. 315,213, 28.5.18.

IN drying machines provided with revolving blades a water pipe is fixed along the blade shaft. By means of the heat of the dryer steam is generated in the pipe and directed on to the blades through nozzles, thus preventing eaking, and possible subsequent "burning" of the material.—W. J. W.

Still-heads. T. H. Durrans, and A. Boake, Roberts and Co., Ltd. E.P. 142,330, 30.5.19.

APPARATUS similar to that described in E.P. 19,999 of 1908 is constructed with a continuous, uninterrupted spiral having the convolutions of varying pitch, or it is formed of a number of sections bolted together, the spiral being of decreasing pitch from section to section upwards, but of the same pitch throughout each section.—W. H. C.

Distillation column. Zimmermann und Jansen, G.m.b.H. G.P. 316,491, 17.8.17.

A COLUMN particularly adapted for the distillation of liquids containing suspended matter, as any section can be readily cleaned, consists of a number

of annular receptacles, *f*, between which are annular vessels, *d*, attached to a central shaft, *b*, by discs, *c*. Each section is provided with a removable door, *e*, in the outer wall, *a*, and thus, by rotating the central shaft, any part of the interior is readily accessible.—L. A. C.

Filter-press frame. G. F. Miller. U.S.P. 1,337,251, 24.4.20. Appl., 17.6.19.

INSIDE the frame proper is placed a removable cloth-holding frame, and a channel for the material to be filtered is made all round the inside circumference of the frame proper, with radial passages leading from the channel through the cloth-holding frame.—B. M. V.

Filtering apparatus. J. M. Izquierdo. U.S.P. 1,337,517, 20.4.20. Appl., 10.12.18.

A NUMBER of pairs of sloping filtering surfaces are arranged in a casing, the surfaces of each pair sloping in the opposite direction relatively to each other and to the surfaces of the pair next below, so that the material to be filtered takes a zigzag course from top to bottom of the apparatus.

—B. M. V.

Filtering-belt. J. A. McCaskell. U.S.P. 1,338,232, 27.4.20. Appl., 21.6.18.

A FILTERING belt with an interior fluid space is provided with a filtrate collector associated with the belt and having independent fluid passages. Flexible conductors connect the fluid space of the belt to the fluid passages, and are wound and unwound during the travel of the belt. Discharge of the filtrate is controlled.—J. H. J.

Filter; Rotating-screen —. C. L. Peck, Assr. to The Dorr Co. U.S.P. 1,338,999, 4.5.20. Appl., 5.10.18.

A PERFORATED hollow cylinder is rotated in a tank containing the material. The material flows from the tank through the cylindrical surface of the screen, and from the interior of the screen through an axial opening at one end arranged directly opposite to a corresponding opening in the wall of the tank.—B. M. V.

Furnace gas-producer. L. M. Underwood. U.S.P. 1,337,298, 20.4.20. Appl., 10.3.19.

IN a kiln provided with a stationary furnace and gas-producer chamber, the latter communicates with the combustion chamber to which an independent air supply is maintained. The portable furnace grate consists of a series of hollow, tilting bars each provided with an end nozzle, into which steam and air are injected, and with a row of tuyères, along the top, through which these gases are passed into the fuel bed.—W. E. F. P.

Muffle furnaces; Method of heating —. W. Zieren. G.P. 317,888, 17.10.18.

TO prevent local overheating of a muffle, the furnace is so built that the hot gases enter through cavities between the outer wall and the top and bottom of the muffle; after leaving the muffle, the hot gases are conveyed away through flues, heated again by the furnace, and returned to the muffle.

—L. A. C.

Catalysers; Apparatus for making —. W. D. Richardson, Assr. to Swift and Co. U.S.P. 1,338,698, 4.5.20. Appl., 26.11.15.

A VERTICAL, cylindrical reduction chamber, provided with a heating coil, downwardly acting propeller agitators carried on a vertical shaft, and a perforated coil for introducing reducing gases, communicates with a baffle chamber where the gases and liquids are separated and which is connected to a vacuum pump.—W. H. C.

Catalyst and process for producing the same. N. Sulzberger. U.S.P. 1,338,709, 4.5.20. Appl., 28.5.15.

A BORATE of a metal possessing catalytic activity is reduced, sufficient of the borate radical being present to serve as an effective carrier of the catalytic metal after reduction.—W. H. C.

Emulsification; Method of and apparatus for —. C. E. Norcross. U.S.P. 1,338,996, 4.5.20. Appl., 12.11.19.

THE materials to be emulsified are delivered to the rotor of a centrifugal machine which is provided with an extremely narrow outlet passage, through

which the materials impinge against a wall which also is part of the rotor.—B. M. V.

Emulsions and suspensions; Thickening, drying, and effecting chemical reaction in —. G. A. Krause. G.P. 303,942, 7.6.16. Addn. to 297,388.

THE emulsion or suspension enters a vaporising chamber through atomisers and is sprayed in all directions in a horizontal plane against a stream of gas for drying or reacting with the particles.

—L. A. C.

Separating condensable vapours from air; Apparatus for —. J. S. Fries Sohn. G.P. 316,652, 21.1.11.

Air containing vapours of volatile liquids is led through a cooling tube containing an inner tube provided at intervals with projections which extend nearly to the outer tube. The latter is thus divided into compartments separated by annular nozzles formed by the projections and the wall of the outer tube. The cooling action is thereby improved.

—J. S. G. T.

Electrical precipitation; Device for — employing high-tension current. Siemens-Schuckertwerke, G.m.b.H. G.P. 316,790, 1.4.16.

HIGH-TENSION rectifying valves are installed in such manner that they can convey at least double the normal working current of the installation, and provide at least one and a half times the working tension, the excess in normal working being taken up by resistances.—J. S. G. T.

Electro-osmotic dehydration of vegetable, animal, and mineral material; Process and apparatus for —. Elektro-Osmose A.-G. (Graf Schwerin Ges.) G.P. 317,403, 13.12.17.

DURING the first stage of the process the volume of the dehydrating chamber is kept constant, and fresh material is introduced continuously, the charge being subjected to the pressure of the material being fed to the chamber or to external pressure. When the supply of material is interrupted, the volume of the dehydration chamber is diminished by causing the electrodes to approach one another, the movement of the electrodes being effected automatically and controlled by the pressure in the chamber.

—J. S. G. T.

Crushers. R. E. Trottier. E.P. 132,503, 25.8.19. Conv., 12.9.18.

Hot air; Means for producing —. H. A. M. Pederson. E.P. 136,160, 2.12.19. Conv., 18.1.19.

Raising water or other fluids by compressed air, through special reversing valve, automatically operated. E. J. H. Norman. E.P. 141,773, 17.12.18 and 13.5.19.

Centrifugal apparatus with planetary movement. W. Mauss. U.S.P. 1,339,272, 4.5.20. Appl., 4.9.19.

Crystallisation from solution; Effecting —. Norsk Hydro-Elektrisk Kvaestofaktieselskab. E.P. 131,207, 13.10.19. Conv., 23.10.18.

SEE U.S.P. 1,329,158 of 1920; J., 1920, 392 A.

Heat treatment of chemical compounds; Apparatus for — and method for operation thereof. F. X. Govers. U.S.P. 1,297,833, 18.3.19. Appl., 18.7.18.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal dust and fusain. F. S. Sinnatt, H. Stern, and F. Bayley. Bull. 5, Lancs. and Cheshire Coal Res. Assoc., 1920, 19 pp.

COAL dust produced during normal working in the pits by natural fracture of the coal may have properties and composition quite distinct from those of coal dust obtained by pulverising lump coal. Fusain (J., 1919, 452 A) is found in naturally-produced dusts in much greater quantity than in the mass of coal. It possesses little cohesive power, the coal therefore fracturing most readily along planes in which it occurs, exposing surfaces of coal covered with a layer of fusain, which quickly powders on exposure to the air. Dust from a dust collector attached to a belt picking room, and of which 95 by weight would pass through a sieve of 1-90th mesh, was found to contain about 49% of fusain. Fusain ignites with considerable ease at a low temperature, and continues to smoulder at a dull red heat without flame or odour, and may have a marked influence upon the tendency of a seam to produce gob fires.—W. P.

Sub-bituminous coal: Low-temperature distillation of —. H. K. Benson and R. E. Canfield. J. Ind. Eng. Chem., 1920, 12, 443-446.

In the distillation of sub-bituminous coal from Newcastle, Wash., which was unsuitable for commercial fuel, the maximum yield of tar oils was obtained at 350° C. About 3.5% of the coal was converted into crude oils composed of a mixture of tar oils and petroleum-like oils, whilst the yield of paraffin wax was about 5.3 lb. per ton of coal. The gas liberated up to 600° C. was small in quantity; it was relatively rich in illuminating hydrocarbons, but low in calorific value. The tar water yielded an appreciable amount of ammonia and a small amount of cyanides. A temperature of pronounced decomposition (between 350° and 450° C.) was observed in the destructive distillation of this coal corresponding to a sudden increase in the yields of hydrogen and methane and of the quantity of oil distilled. The residue left at 350° showed an increase of 22.8% in calorific value as compared with the coal as mined, and of 14.7% over the dry coal.—C. A. M.

Naphthenes: Occurrence of — in Galician crude oil. F. J. Skowronski. Metan, 1918, 61-67, 73-79, 86-91, 97-105, 109-118. Chem. Zentr., 1919, 90, IV., 585; 1920, 91, II., 655.

PETROLEUM from Tustanowic (sp. gr. 0.8766 at 25°/1° C., 1.34, distilling below 150° C., 29-12 below 300°, and 67.95% residue, hard asphalt content 1.59%, soft asphalt 4.17%, wax 8.37%) was fractionated, the fractions were purified, freed from unsaturated hydrocarbons by treatment with cold fuming sulphuric acid, and tested for naphthenes by heating with iodine to oxidise the naphthenes, and then brominating in the presence of ferric chloride. Galician oil is midway between American and Russian oils in its content of naphthenes. There have been identified definitely hexanaphthene (cyclohexane), heptanaphthene (methylcyclohexane), octonaphthenes (1,2-, 1,3- and 1,4-dimethylcyclohexanes), nononaphthene (1,2,4-trimethylcyclohexane), α - and β -decanaphthenes, and also hexahydro-*p*-xylene (not hitherto observed in petroleum). The decanaphthenes appear to be dimethylethylcyclohexanes).—A. E. D.

Water in petroleum and other organic emulsions: Determination of —. E. W. Dean and D. D. Stark. J. Ind. Eng. Chem., 1920, 12, 486-490.

DISTILLATION in the presence of an immiscible solvent is the most trustworthy method of determin-

ing water in petroleum or other organic emulsions. A 500 c.c. round-bottomed distillation flask is connected to a "distilling tube receiver," made by fusing a side tube to a tapered graduated test tube. This side tube passes through the stopper of the flask, whilst the lower end of a rellux condenser is fitted into the cork of the test tube. A commercial naphtha or a mixture of commercial xylene with 20% of commercial benzene gives good results as immiscible solvent. The emulsion (100 c.c.) and solvent (100 c.c.) are distilled at the rate of 2 to 4 drops per sec., until all water in the flask, distillation tube, and condenser has disappeared (about 1 hour) and the volume of water collected in the graduated tube is read. For the determination of less than 0.5% of water in an emulsion 200 c.c. of both emulsion and solvent are used. The method gives good results with coal-tar emulsions, using the xylene-benzene solvent.—C. A. M.

Sulphur in [petroleum] oils; New method of determining —. C. E. Waters. J. Ind. Eng. Chem., 1920, 12, 482-485.

FROM 0.5 to 1.5 g. of the oil is treated with 5 c.c. of concentrated nitric acid, saturated with bromine, and the crucible covered with a watch glass and heated for about 30 mins. on a steam bath, and finally for 2 to 3 hours in direct contact with the steam. From 10 to 12 g. of anhydrous sodium carbonate is then introduced beneath the crucible cover in successive small portions, and the resulting pasty mass dried on the steam bath at 100° C., and ignited over a low flame. It is then digested with about 150 c.c. of water, the aqueous solution filtered, the filtrate acidified with hydrochloric acid (about 2 c.c. in excess), and the sulphate precipitated as barium sulphate. A blank test should be made with the reagents. For heavy and vulcanised oils the method gives results as accurate as those obtained with the bomb calorimeter.—C. A. M.

Mineral oil refining; Recovery of waste acids from —. E. A. Kolbe. Petroleum, 1919, 14, 837-847. Chem. Zentr., 1919, 90, IV., 197.

ABOUT 90% of the sulphuric acid in the waste acids from lubricating oil refining may be recovered in the form of sulphur dioxide by heating the waste acid; a lower temperature is required for the decomposition, less pitch is formed, and the sulphur dioxide contains less sulphur trioxide when the waste acid from lubricating oil refining is mixed, before heating, with waste acid from petroleum (burning) oil refining.—W. P. S.

Paraffin wax; New sweating process for —. A. Székely. Petroleum, 1919, 15, 109-111. Chem. Zentr., 1920, 91, II., 23-24.

CRUDE melted paraffin wax is introduced into a vessel, partly immersed in water, constructed with perforated walls and containing perforated tubes. Those parts above the water-level are protected by solid walls and tubes until the wax has solidified sufficiently not to pass through the perforations. After removal of the protective coverings the cake may be subjected to moist or dry sweating, or a combination of both. Sharp fractionation and the production of a valuable product from inferior material are effected.—C. A. M.

Montan wax; Resinous constituents of —. J. Marcusson. Braunkohle, 1919, 17, 245-247. Chem. Zentr., 1920, 91, II., 417-418.

THE products hitherto described as montan resin contain large quantities of wax; e.g., 100 g. of the resin obtained by the technical method of extraction with toluene, when dissolved in 300 c.c. of ether and treated with an equal volume of 96% alcohol, gave 56 g. of precipitated wax and a further quantity on cooling to -20° C. From the mother liquor two resin fractions of 12.5 and 19.8 g.

respectively were obtained by partial and complete removal of the solvent. The second of these fractions was completely soluble in 96% alcohol, whilst the first was only slightly soluble even on boiling. The behaviour of these resins towards sulphuric acid and nitric acid was compared with that of lignite extracted with benzene. It is concluded that the former are probably the remains of plant resins originally present in the wood. Apart from quantitative differences lignite resembles pit coal in its behaviour to sulphuric and nitric acids. It contains besides mineral constituents, waxes, plant resins, nitrogenous bases, and humic acids, two main constituents, *viz.*, saturated polycyclic compounds containing oxygen in "bridge formation" and resembling in character the chief constituent of pit coal, and also more readily decomposable substances which can be converted into soluble compounds by sulphuric and nitric acids. The transformation of lignite into pit coal may consist in the decomposition of the last-mentioned compounds, and the conversion of the waxes and plant resins into hydrocarbons, which by polymerisation and oxidation yield asphalt-like products.

Fatty acids from petroleum. Ubbelohde and Eisenstein. See XII.

PATENTS.

Powdered fuel; Fluid-pressure apparatus for burning — P. A. Leonard, M. F. Maloney, and E. Friedrich. U.S.P. 1,338,451, 27.9.20. Appl. 16.8.19.

A jet of mixed fuel and air is blown into a furnace, and a jet of air is delivered under pressure in line with, and unobstructed from direct impingement against, the first jet. A volume of air under pressure is also introduced at an angle to the common axial line of the first two jets.—A. G.

Coke ovens. E. Hurez. E.P. 123,099, 6.2.19. Conv., 26.1.18.

In regenerative ovens the circulation of the gases is arranged so that the heating surfaces of the walls of the furnace are all continuously heated by gases in active combustion. The circuits of air and gas are arranged so as to obtain automatically as uniform a distribution as possible in each of the compartments of the furnace, positive control of the gas and air supplies being provided for. The recuperators are formed of specially constructed earthenware blocks, arranged in such a manner that the air or gases to be heated as well as the burned gases traverse them always in the same direction and without the necessity of reversal.

—A. G.

Coke-ovens. G. Hinselmann. G.P. 319,216, 19.10.17.

In a coke-oven plant steam is led through the chambers in which coke formation is almost complete, and the mixture of steam and water-gas obtained is led without fall of temperature into the remaining chambers in which coking is not so far advanced. Residual steam is converted therein to water-gas, and the passage of the heated gases over the coal during the early stages of coking shortens the time of the process and increases the yield of by-products and combustible gas.—L. A. C.

Coke for use in blast-furnaces; Saturating — with chloride solutions. A. Riedel. G.P. 319,550, 4.1.16.

INCANDESCENT coke from coke-ovens is quenched with chloride solutions such as the waste liquors of the potash and soda industries, which are employed in such proportions that the quantity of chloride absorbed by the coke is equivalent to its nitrogen content. The nitrogen is converted to ammonium chloride during combustion of the coke, and is recovered as such.—L. A. C.

Gasification of carboniferous substances; Process and apparatus for — H. Strache. E.P. 117,083, 22.6.18. Conv., 28.6.16.

GASIFICATION is effected in a producer surmounted by a distillation chamber into which the fuel is fed intermittently from a hopper. The producer-gas is partly burnt in flues surrounding the distillation chamber, and the hot gases pass on to a steam superheater, where combustion is completed. The superheated steam is supplied in part to the top of the producer near the junction with the distillation chamber and the remainder through an inlet at the bottom of the producer. Alternatively the whole of the steam may be supplied to the top of the producer, in which case water-gas is withdrawn through an outlet at the bottom. The distillation gases are withdrawn from the top of the distillation chamber. The steam is superheated to a temperature below 800° C. if a high yield of ammonia is desired, or above 800° C. to obtain a high yield of gas.

Gas producing plant. E. H. Crush. E.P. 111,771, 17.12.18.

In gas producers where part of the sensible heat of the gas is used for the generation of steam, to prevent accumulation of dust on the water tubes the gas off-take is situated in the upper part of the chamber, and the water tubes of the steam generator are inclined or curved inwards and upwards. Baffles are arranged so that the producer gas enters radially at several points and changes its path of travel to the off-take.—A. G.

Gas; Method of manufacturing — from coal or like carbonaceous material. C. E. Holt and T. Walker. E.P. 141,828, 4.2.19.

The finely-divided coal is dried by passage through a jacketed hopper, and steam is supplied at comparatively low pressure, so as to flow gently into the heat zone of the retort to meet the falling coal dust.—A. G.

Gas; Method of producing — O. F. Bean. U.S.P. 1,337,637, 20.4.20. Appl., 5.8.19.

SUPERHEATED steam is passed over hot iron to liberate hydrogen. Oil is vaporised, the vapour is raised to the same temperature as the hydrogen, and then added to it. The mixture is passed through a conduit, where its temperature is raised to the gasification point.—J. H. J.

Gaseous fuel; Process of manufacturing — J. R. Rose. U.S.P. 1,339,225, 4.5.20. Appl., 25.1.18.

HYDROCARBON vapours are injected into a space heated by an electric arc, and are thereby dissociated into solid carbon and a gas containing a preponderating amount of hydrogen.—A. G.

Gas; Apparatus for washing — T. H. Hack and H. F. Boughton. E.P. 142,203, 5.2.19.

FLOW tubes for the washing liquid are disposed in circular formation in plan and vertical in elevation, and pressure tubes are so arranged that the gas under pressure issuing therefrom blows freely over and across the mouths of the flow tubes. Similar circles of tubes are fixed at a higher elevation and arranged to intervene in plan. An annular spray of washing liquid is thus produced. In another form of apparatus an inner and outer annular orifice arranged concentrically are formed by means of an adjustable or fixed valve which does not cover the outer orifice. Gas under pressure issuing from one orifice blows freely across the other which induces or is supplied with liquor, and an annular spray is thereby produced. A. G.

Tar extractor apparatus and method. J. Becker, Assr. to The Koppers Co. U.S.P. 1,337,984, 20.4.20. Appl., 2.12.18.

PERFORATED baffle-plates, partially immersed in the

accumulating tar, are used to effect deposition of the tar from the gas. The level of the tar in the chamber is controlled automatically in response to changes in the pressure differential of the gas flow through the baffles.—A. G.

Gas washing apparatus. J. S. Kennedy. U.S.P. 1,339,112, 4.5.20. Appl., 15.1.19.

A CASING is divided into a number of separate unobstructed treating chambers, including a washing chamber wherein the gases are cleansed and a chamber wherein the moisture is precipitated. The flowing gas is subdivided by a horizontal grating in the path of the gases between the washing and precipitation chambers.—A. G.

Washing and absorbing gases; Apparatus for —. W. Steinmann. G.P. 316,594, 20.8.18.

GAS enters the cylindrical washing chamber (see fig.), and is forced to pass through the liquid in *c* in the direction indicated by the arrows, by means of a number of annular rings so arranged that the spaces through which the gas leaves are narrower than those through which it enters the liquid. Any liquid suspended in the gas is removed as it passes upwards to the exit through *p, f, g*. The liquid container, *c*, may be fitted with a heating or cooling coil.

—L. A. C.

Spent oxide; Revivifying —. W. J. Dibdin. E.P. 141,172, 15.3.19.

SPENT oxide on trays with fine wire gauze bottoms arranged in a chamber is heated by a current of steam superheated to about 500° C. to remove the sulphur; the trays are then transferred to a second chamber in which the iron is re-oxidised, and organic matter and residual sulphur are removed by a current of air regulated to avoid too high a temperature. The steam passes into a condensing chamber in which the greater part of the sulphur separates.—L. A. C.

Hydrocarbons and other substances; Decomposition of — in the liquid and/or vapour phase. W. Mann. E.P. 142,206, 6.2.19.

Porous septa are introduced between the decomposition chamber and the condenser, whereby products of lower molecular weight are separated by virtue of their superior velocity of diffusion. —A. E. D.

Distillation of heavy hydrocarbons of petroleum, lignite tar, and coal tar; Distilling boiler for —. L. Steinschneider. E.P. 142,376, 14.8.19.

To avoid the rapid destruction of coking stills an ordinary still is equipped with a series of retorts connected with the lowest part of the still. The coking process takes place in the retorts which are provided with cleaning openings and can be disconnected independently from the still.—A. E. D.

Cracked oils; Refining —. E. H. Leslie and C. Barbre, Assrs. to General Petroleum Corp. U.S.P. 1,337,523, 20.4.20. Appl., 13.9.17.

The oil is heated in the presence of a porous catalyst, then filtered, and distilled to separate any

resinous matter produced in the preliminary heating.—A. E. D.

[Mineral] oil; Apparatus for refining —. Process of and apparatus for refining liquid hydrocarbons. System for cracking mineral oil. Apparatus for cracking hydrocarbons. Apparatus for refining oil. Apparatus for refining mineral oils. Liquid-heating furnace. F. E. Wellman, Assr. to Kansas City Gasoline Co. U.S.P. (A) 1,335,767, (B) 1,335,768, (C) 1,335,769, (D) 1,335,771, (E) 1,335,772, (F) 1,335,773, (G) 1,335,774, 6.4.20. Appl., (A) 15.9.15, (B) 30.12.15, (C) 7.10.16, (D) 15.1.17, (E) 12.5.17, (F) 21.1.18, (G) 9.4.18.

(A) OIL, heated under relatively low pressure in a preheater, is pumped into a superheater and maintained under pressure and at a relatively high temperature (B) Oil vapour is compressed and introduced into a retort heated to a temperature sufficient to crack the oil. The vapour produced is withdrawn near the bottom of the retort and passed upwards through a separate coil wherein different products are recovered by fractional condensation. (C) Oil is heated in a cracking coil jacketed with a lagged steam pipe. Superheated steam is simultaneously fed into the coil in a whirling spray. (D) A cracking still is provided with valved charging and discharging ports. An automatic pressure-operated relay valve operates the discharge valve at any desired pressure. (E) A tubular retort has inlet and discharge pipes at opposite ends, the discharge pipe being at the bottom of the retort. Charges of oil are fed intermittently into the retort, and provision is made for scouring the retort in the intervals between discharging and charging. (F) A cracking coil of large diameter is provided with feed and discharge pipes of smaller diameter. A pressure valve at the discharge end of the cracking coil is connected to a cooling coil of the same diameter as the cracking coil, and a safety discharge valve at the feed end of the cracking coil is connected to a cooling coil of the same diameter as the feed pipe. (G) A liquid-heating furnace is composed of horizontal layers of parallel pipes. A number of combustion chambers and flues are provided, and means for controlling them independently. An even longitudinal distribution of heat is thereby achieved.—A. E. D.

Hydrocarbon oils; System for treating —. F. E. Wellman and F. H. Sibley, Assrs. to The Kansas City Gasoline Co. U.S.P. 1,335,770, 6.4.20. Appl., 19.10.16.

OIL is cracked in a still under a suitable pressure. The still is heated with steam superheated to the desired temperature.—A. E. D.

Motor fuel; Composite —. Method of distilling. A. Hayes, Assr. to A. F. Ray. U.S.P. 1,338,983 and 1,338,984, 4.5.20. Appl., 19.9.19.

ALCOHOL-CONTAINING material is distilled and ether is added to the vapour during condensation to obtain a motor fuel containing alcohol, ether, and water, the amount of water present being greater than that of ether.—A. E. D.

Mineral oils; Substitute for — [from tar oils] for use in switches and transformers. Tetralin G.m.b.H. G.P. 299,691, 7.2.17.

SULPHUR compounds, fatty acids, and unsaturated compounds are removed from tar oils, yielding a product suitable for use in electric switches and transformers, by heating the crude or distilled oils with a finely divided or readily fusible metal, metal hydride, or other metallic compound in which the metal is only loosely combined with a non-acidic residue; the process may be supplemented by catalytic hydrogenation of the oil, e.g., by introducing hydrogen under pressure during the above treat-

ment. Suitable metals or metal compounds are sodium, potassium, copper, iron, finely divided nickel, calcium hydride, sodamide, calcium carbide, or the like, and other finely divided or porous materials, such as fuller's earth, and a solvent or diluent may also be added. Lignite tar fuel oil can be purified sufficiently for lubricating machinery by agitation above 100° C. with metallic sodium or potassium.—L. A. C.

Lubricating oils; Production of — from coal tar oils. H. Klever. G.P. (A) 301,775, 19.2.15, and (B) 301,777, 8.4.15. Additions to 301,774 (J., 1920, 327 A).

(A) THE tar oils may be heated under pressure at temperatures up to 100° C., or at atmospheric pressure under a reflux condenser, and preferably in absence of air. The highly viscous oils obtained may be used for thickening less viscous tar oils. Catalysts such as iron, copper, or other metallic powders, may be used. (B) Bases or phenols or both together may be added, or they may first be heated by themselves and the viscous products thus obtained may be used for thickening other tar or pitch oils. Alkalis and metal hydroxides have been successfully used as catalysts.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood charcoal; Activation of — by heat treatment. J. C. Philip, S. Dunnill, and O. Workman. Chem. Soc. Trans., 1920, 117, 362–369. (Cf. J., 1920, 363 A.)

THE main factor in determining the degree of activation, or increase of absorptive power, of wood charcoal resulting from prolonged heating, is not the duration of such heating, but rather the alteration of bulk density of the charcoal as a result of oxidation during the heat treatment by adsorbed oxygen, which causes an opening up of the capillaries, and a large increase of effective surface. The activated charcoal shows an increased absorptive power for colouring matters as well as for gases. For example, a sample of Japanese ash charcoal which only removed 0.6% of methylene blue from aqueous solution removed 60.3% after 19 hours' heat treatment at 830° C., considerably surpassing the activity of ordinary animal charcoal. It seems improbable, therefore, that the activity of animal charcoal can be correctly correlated with its nitrogen content, nor does the absorptive power depend on any specific inorganic constituents in the ash. The charcoal must be heated at a temperature not lower than 800° C. for any rapid improvement in absorptive power to take place. Further, whilst charcoals from light woods, such as willow and poplar, are activated more rapidly, they are ultimately surpassed in activity by charcoals derived from denser woods such as box.—G. F. M.

Rice chaff; Distillation of — to obtain acetic acid and furfural. F. Scurti and C. E. Zay. Staz. Sper. Agrar. Ital., 1919, 52, 278–290. Chem. Zentr., 1919, 90, IV., 1105.

Rice chaff contained: Water, 9.0; fat, 0.5; crude

proteins, 3.5; cellulose, 42.0; ash, 18.0; and N-free extractives, 27.0% (including 17% pentosans). To obtain acetic acid and furfural simultaneously it is best to distil 1 pt. of the chaff with 10 pts. of 30% H₂SO₄, and to keep the acid concentration of the liquid constant by adding water until 3 pts. of distillate have been obtained. The concentration of the acid in the distillation vessel is then raised to 50% by distilling a further 4 pts. The distillate will contain the whole of the furfural formed from the pentosans. An additional 3 pts. is then distilled to obtain the acetic acid. The first fraction is neutralised with sodium carbonate, the furfural distilled and purified by repeated distillation with sodium chloride. The neutral solution left after the distillation and the neutralised second fraction contain sodium acetate. 1 kg. of chaff yields 40 g. of furfural and 110 g. of sodium acetate.—C. A. M.

PATENTS.

Coal, carbonaceous material, oil shales, and the like; Distillation, carbonisation, or gasification of —. J. E. Christopher. E.P. 142,163, 30.12.18.

A RETORT or chamber has a main external heating flue and two auxiliary chambers, flues, or regenerative sections, or two series thereof connected thereto and controlled by dampers and the like, the arrangement being such that heating gas, with air if necessary, is admitted to the main external flue, the products of combustion passing alternately into one or other of the connected auxiliary chambers, flues, or regenerative sections or series thereof according to the setting of the dampers or the like, and thus further heating the retort or chamber.—A. G.

Coal; Process for the distillation of —. T. Limberg. G.P. 303,951, 15.10.16.

THE process is specially adapted for the treatment of coals rich in water and bituminous matter, such as bituminous shale and peat, for the purpose of obtaining a light tar with a high content of aliphatic hydrocarbons. The material is heated in a specially constructed oven at reduced pressure and at a temperature somewhat below dull redness, and the products of distillation are drawn off along the whole length of the oven into a series of separate vessels. The material may be arranged in layers in the oven and draw-off and internal heating devices provided between the layers.—B. V. S.

Wood distillation; Process for —. C. T. Clark, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,337,342, 20.4.20. Appl., 11.8.17.

WOOD, which has been cut transversely to the grain into plaques the dimension of which parallel to the grain is less than a dimension perpendicular to the grain, is heated, introduced into a retort, and then subjected to destructive distillation.—A. de W.

Wood being distilled; Holder for —. A. C. Badger, Assr. to E. B. Badger and Sons Co. U.S.P. 1,338,667, 1.5.20. Appl., 26.7.16.

A HOLDER capable of introduction and withdrawal from the retort, has separate compartments for the wood to be distilled and spaces between the compartments open above and below to permit of the escape of the products of distillation.—A. G.

Wood-tar and pyroligneous acid; Method of separating —. W. E. Clifford. U.S.P. 1,339,022, 4.5.20. Appl., 25.6.18.

THE liquor is maintained in a heated state and agitated by aeration, afterwards being allowed to settle into separate layers.—A. G.

Gas mantles; Manufacture of — from cellulose. Deutsche Gasglühlicht A.-G. (Auerger.). G.P. 312,577, 27.2.18.

CELLULOSE threads are converted partially into

hydrocellulose; the mantles made from these threads have properties similar to those of ramie and artificial silk mantles.—W. P. S.

Lower boiling hydrocarbon [toluene]; Production of — from higher boiling hydrocarbon [xylene]. A. E. Houlehan, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,337,317, 20.4.20. Appl., 25.5.17.

XYLENE is subjected to the action of a catalyst whereby toluene is produced. The toluene is distilled off under vacuum as it is formed.—A. E. D.

Colourless organic compounds; Manufacture of —. South Metropolitan Gas Co., and H. Stanier. E.P. 141,440, 18.1.19.

DISCOLORATION in aromatic amino- or hydroxy-compounds, such as β -naphthol, benzidine, sulphanilic acid, or naphthionic acid is removed by treatment of a solution or suspension with a small proportion of a hydrosulphite or of a sulphonylate; similarly discoloration may be prevented, e.g. in the product obtained on heating a sulphonic acid with caustic soda solution by the addition of a small proportion of hydrosulphite or sulphonylate to the reagents.—D. F. T.

Decahydronaphthalene; Purification of —. Tetralin Ges. G.P. 310,781, 29.9.17.

THE crude product obtained by the incomplete hydrogenation of naphthalene is treated with liquid sulphur dioxide, which readily dissolves naphthalene and its lower hydro-derivatives, whereas decahydronaphthalene is almost insoluble in this solvent.

Chlorinated nitronaphthalenes; Manufacture of —. O. Matter. G.P. 317,755, 12.2.18.

CHLORINE addition products of naphthalene are treated with nitric acid at low temperatures, and the products are heated with water or a compound capable of combining with an acid. Nitronaphthalene dichloride, prepared by the action of nitric acid (sp. gr. 1.5) on naphthalene dichloride, on heating with water or milk of lime yields 1,8-chloronitronaphthalene, m.p. 93°–94° C.; this on reduction with stannous chloride and hydrochloric acid forms 1,8-chloronaphthylamine, m.p. 88°–89° C. Naphthalene tetrachloride on treatment with nitric acid (sp. gr. 1.5) yields a resinous nitro-compound, which by heating with methyl alcohol and sodium hydroxide, or with benzene, methyl alcohol, and sodium carbonate to 140°–150° C., is converted into 5,8-dichloro-1-nitronaphthalene, m.p. 94° C.; this on reduction with tin and hydrochloric acid forms 5,8-dichloro-1-naphthylamine, m.p. 104°–105° C.—L. A. C.

Chlorinated derivatives of naphthalene of waxy consistency; Production of —. Chem. Fabr. Griesheim-Elektron. G.P. 319,253, 21.10.16.

NAPHTHALENE is treated with chlorine at 100°–170° C. in the absence of a halogen carrier until the reaction product contains 50–57% Cl. This pro-

duct, containing approximately a tetra-atomic proportion of chlorine, possesses an advantage over the more highly chlorinated derivatives in that it is non-crystalline and free from brittleness. A softer wax may be obtained by checking the chlorination when the reaction product has attained a solidifying point of 118°–120° C.; for a harder product the solidifying point is allowed to rise to 126°–128° C. The products have sp. gr. 1.55–1.65.—D. F. T.

2-Aminoanthraquinone; Process of making —. M. Fischer, Assr. to J. R. Geigy S.A. U.S.P. 1,338,363–4, 27.4.20. Appl., 16.10.19.

IV.—COLOURING MATTERS AND DYES.

Indigotin; Continuous scheme for preparation of — from phthalimide. P. Holland. Chem. News, 1920, 120, 208–209.

ANTHRANILIC acid was prepared by slowly adding 10 c.c. of sodium hypochlorite solution (5.1% available chlorine) to a solution of 1 g. of recrystallised phthalimide and 2 g. of pure sodium hydroxide in 10 c.c. of water; after standing for 15 mins. 0.1 g. of sodium bisulphite was added, the solution was partially neutralised with sulphuric acid, and then faintly acidified with acetic acid. Anthranilic acid was converted to *o*-carboxyphenylaminoacetonitrile by adding an acidified solution of 1.2 g. of sodium cyanide and 2 c.c. of 37–38% formaldehyde to 1 g. of anthranilic acid dissolved in sufficient sodium hydroxide to give a faintly alkaline solution. After standing for 2 hrs. the solution was diluted with 200 c.c. of a cold saturated solution of the nitrile, filtered, washed with more saturated solution, and dried. A yield of 117.1% of nitrile from phthalimide was obtained. Indigotin was prepared from phthalimide without isolation of intermediates by drying the solution obtained in the preparation of the nitrile together with 10 g. of sodium hydroxide, heating the product covered with paraffin wax in a nickel crucible to 270°–275° C., and subsequently converting the sodium indoxylate in the melt to indigotin in the usual manner. Sodium phenylglycine-*o*-carboxylate was prepared from phthalimide by drying the solution of sodium anthranilate and sodium sulphate, adding the requisite weight of sodium monochloroacetate, and warming to 30° C., keeping the mass slightly alkaline; the sodium hydroxide fusion was then carried out as before.—L. A. C.

Anthocyanin colouring matters of the beet-red group; Occurrence and reactions of —. F. Kryz. Oesterr. Chem.-Zeit., 1920, 23, 55–56.

MEMBERS of the beet-red group of anthocyanins occur in the skins of fuchsia and cactus berries and in the petals of scarlet cactus blooms. Fuchsia anthocyanin gives a carmine solution in acidified acetone or amyl alcohol, but is insoluble in ether, chloroform, and carbon bisulphide. Cactus bloom anthocyanin is also insoluble in these media, but soluble in water, methyl, ethyl, or acidified amyl alcohol, and in glycerin. The colouring matter from red beet is soluble in cold acetone and similar to the others in its behaviour towards reagents. Wing cactus blooms apparently contain two anthocyanins, since the reddish-yellow extract obtained with hot acetone shows slight differences from the foregoing compounds, whilst the aqueous solution of the residue exhibits close agreement. Isocyanine dyes. Mills and Pope. See XXI.

PATENTS.

Disazo dyestuffs; Manufacture of mordant-dyeing — and their application in dyeing and printing. Manufacture of mono-azo dyestuffs. O. Imray. From Society of Chemical Industry in Basle. E.P. (A) 111,101 and (B) 111,613, 10.12.18.

(A) MORDANT-DYEING disazo dyestuffs are prepared by diazotising the mono-azo dyestuffs described under (B) and coupling with an aminonaphtholsulphonic acid, an acetylammonaphtholsulphonic acid, or a pyrazolone containing a carboxyl group or a carboxyl group and a hydroxyl group in the aryl residue. The products give, after chroming, fast yellow to red or greenish-blue tints on wool and similar tints when chrome-printed on cotton. (B) Yellow to orange monoazo dyes applicable in wool dyeing and in chrome printing on cotton are made by combining diazo compounds with methyl- α -sulphonic acids of the type $R.NH.CH_2.SO_3H$, where R is an aromatic radical, and subsequently eliminating the N-methyl- α -sulphonic acid group.

—A. J. H.

o-Hydroxyazo-dyestuffs; Substantive —. E. Anderwert and H. Fritzsche, Assrs. to Soc. Chem. Ind. in Basle. U.S.P. 1,335,111, 27.4.20. Appl. 11.6.19.

AZO-DYESTUFFS dyeing unmordanted cotton direct tints sensitive to alkalis and acids and giving by treatment with coppering agents on the fibre cleared to blue-violet tints fast to alkalis, acids, and light, are prepared by coupling the diazo derivative of an *o*-amino-hydroxyarylsulphonamide of the formula (1)OH.(2)NH₂.R.SO₂NHX (where R is an aryl radical which may be further substituted, and X is hydrogen or an aryl radical) with a 2,5,7-aminonaphtholsulphonic acid compound in which a hydrogen atom of the amino group is substituted by one of the groups C₆H₅—, C₆H₄CO—, C₆H₄.(3)NH₂.(4)CO—, C₆H₄.(7)SO₃H.(5)OH.(2)NH₂CO—, —C₆H₄.(3)SO₃H.(5)OH, or C₆H₄.(7)SO₃H.(5)OH.(2)NH₂CO(1)—C₆H₄.(3)NH₂CO—(3)NH₂.C₆H₄—(1)CO—.

—L. A. C.

Black [sulphur] colouring material; Preparation of a —. H. R. Vidal. E.P. 141,759, 10.1.17.

A MIXTURE of 40 kg. of 1,2,4-dinitrophenol, 100 kg. of crystalline sodium sulphide, 20 kg. of commercial cresol, 25 kg. of sulphur, and 100 l. of water is boiled under a reflux condenser for 4–5 hrs., and the colouring matter is precipitated from the product by air or acid. The dye is soluble in sodium sulphide, and dyes cotton a direct black which does not bronze, has no grayish reflection, and is fast to chlorine.—L. A. C.

Triarylmethane dyestuffs suitable for after-chroming; Production of —. Farb-fabr. vorm. F. Bayer und Co. G.P. 318,956, 14.10.11.

THE products obtained by the condensation of sulphonated dyes, derived from aromatic aldehydes and hydroxycarboxylic acids, with aromatic amines (G.P. 287,003; J., 1916, 171) give feeble, dull and unequal shades in cotton printing, but on further sulphonation superior dyestuffs are produced of much more than double the intensity.

—D. F. T.

Dye recovery. E. J. Wall, Assr. to Kalms, Comstock and Wescott, Inc. U.S.P. 1,337,673, 20.4.20. Appl. 18.5.17.

FIBROUS cellulose material is immersed in a dye

solution to absorb the dye, which is subsequently extracted from the material by a suitable solvent.

—L. A. C.

Ind. E.P. 111,631. See XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Retting of textile plants in Italy. D. Carbone. Bull. Agric. Intell., 1919, 10, 177–179. (See J., 1918, 25 A.)

THE retting of hemp submerged in water is effected by a slender bacillus, *B. felsineus*. This could never be obtained quite free from *Amphibacter*, and it is possible that the latter may be a special form of the micro-organism. This bacillus sometimes occurs in chains, forms elongated spores like those of *Clostridium*, and produces orange-coloured colonies on agar must. When grown alone it is strictly anaerobic, but it can also live aerobically in symbiosis with other organisms, notably *Saccharomyces ellipsoideus*. Its retting action on textile plants differs from that of aerobic bacteria of the *B. asteropus* group, for it separates the bark in wide strips, whereas after the action of the latter the bark is still attached to the fibres. *B. felsineus* is found on unretted hemp, on the surface covering of retting pits, and in the mud of water in communication with the pits. Its optimum temperature is 37° C. It has given good results in the retting of ramie, *Furcraea*, and *Sansevieria*, and also of broom, nettle, mallow, etc.—C. A. M.

Best fibres; Retting of —. W. P. Kraus, Z. angew. Chem., 1920, 33, 102–103. (Cf. J., 1919, 169 A, 530 A; 1920, 11 A.)

FURTHER work is described dealing with the retting of fibrous materials by steeping in a 0.5–1.0% solution of sodium bicarbonate for 3–5 days. The addition of a small quantity of sodium sulphite to the retting liquor greatly improves the colour of the resulting fibres without much retarding the action, but, apparently owing to the formation of sulphur compounds, an extremely disagreeable odour is produced. This can be reduced by the simultaneous addition of dextrose to the retting liquor. Bacteriological tests showed the retting to be largely dependent on the activity of *Plectridia*. The fibres obtained on a large scale trial of this method were much superior to those ordinarily obtained.

—A. J. H.

Cellulose; Titration of —. W. Qvist. Pulp and Paper Mag., 1920, 18, 261–262, 285–287.

THE alkalinity of various samples of cellulose was determined using an ether solution of iodeosine as indicator. Samples of sulphite-cellulose had an alkaline reaction which diminished on repeated extraction with water to a neutral or faintly acid reaction. Bleached samples were less alkaline than unbleached. Sulphite-cellulose heated at 100° C. for a long time became acid, but became alkaline after prolonged extraction. Sulphate-cellulose and wood pulp reacted alkaline. Hydrocellulose and oxycellulose had an acidic reaction which became alkaline on washing. The alkalinity of the samples of cellulose is probably connected with the alkalinity of the river water with which the samples were prepared. Experiments showed that cellulose, especially oxycellulose, could absorb both acids and alkalis from solutions.—A. J. H.

Paper pulp from flax straw. Pulp and Paper Mag., 1920, 18, 315–350.

IN view of the demand for paper pulp, its production from flax straw would be profitable. The process of manufacture has been shown possible on

a semi-commercial scale. In 1919 Canada grew sufficient flax to produce 100,000 tons of pulp. Pulp from flax straw is comparable to that obtained from a fair grade of cotton rags.—A. J. H.

Paper pulp manufacture; Recovery of alkali from "black liquor" obtained in —. H. K. Moore. Paper, 1920, 25, 1157—1161, 1197—1201, 1241—1246.

THE "black liquor" is treated with salteake and passed through a coil heated well above 100° C. and sprayed into a combustion chamber where it is immediately vaporised. The "black liquor" particles are at once evaporated to dryness, ignited, and the alkaline products are condensed on the surface of a boiler, whereby the heat developed is utilised. The fused alkaline product percolates through the char on the bottom of the chamber, whereby the formation of sodium sulphide is completed, and thence passes to a dissolving tank. The combustion chamber is supplied with a blast of low-pressure air, but no extra fuel is needed.—A. J. H.

Colloidal rosin in beater sizing [of paper]. J. Traquair. Paper, 1920, 26, 185—186.

IF rosin size and an alum solution be mixed in the presence of a colloid, the precipitate of aluminium resinate is colloidal in character and is much more efficient for paper sizing. In practice, 50—66% of the usual amount of rosin sizing required can be saved with the production of an equally hard sized paper. The most suitable colloid is feculose (starch acetate). It is four times more efficient than maize starch, and the amount required is 18% on the weight of dry rosin.—A. J. H.

PATENTS.

Hemp; Manufacture of imitation —. H. Nishimura. Assee. of T. Honda. E.P. 130,590, 11.7.19. Conv., 27.7.18.

COTTON thread is drawn through a solution of Konnyaku-nori (a paste or size made by grinding the root of *Hydrosme rivieri* with water, which is converted into a white insoluble compound by tannic acid), and then through a $\frac{1}{2}$ —1% solution of tannic acid. The nap on the fibre is laid down and a hemp-like appearance is obtained. By boiling the treated thread for about 5 mins. in a 0.3—0.7% solution of sodium stannate or a 1—3% sodium silicate solution, a translucent lustre is produced. The treated threads can be dyed directly with basic dyestuffs.—A. J. H.

Flax; Production of fibres from —. W. J. Robinson. E.P. 141,982, 21.7.19. Conv., 23.4.19.

IN fibrous plants the fibres are bound to the woody portion by means of a cutose gum, while they are held end to end by a pectous gum. By the following procedure the cutose gum may be disintegrated without destroying the pectous gum. Flax straw is soaked in a saturated salt solution at 43° C., drained, and then exposed to the action of a hot or boiling liquid containing 10—20 lb. of an almost completely saponified oil (preferably the product obtained from flax seed) per 100 galls. of water. The addition of one pint of turpentine per 2 galls. of liquid is desirable. The fibres are secured to the surface of a drum which revolves partly immersed in the liquid, so that the fibres are alternately immersed in the liquid and exposed to the air. The cutose gum is disintegrated by this treatment, and after 45 mins. the drum is removed and revolved in a washing tank, then in a slightly acid bath, and finally rotated in a drying chamber at 110°—130° F. (43°—55° C.). Fibres thus prepared are three-quarters bleached and very lustrous.—A. J. H.

Artificial silk; Method and means for manufacture of —. C. L. Stulemeyer. E.P. 142,038, 5.11.19.

IN forming artificial fibres the jets through which the cellulose solutions are squirted are made of molybdenum, which is not affected by acids and alkalis, and is cheaper and stronger than platinum.—A. J. H.

Textile fibres; Production of — from wood. L. Enge. G.P. (A) 302,424, 13.3.17, (B) 303,293 24.6.17, (C) 304,313, 26.6.17, and (D) 304,312, 2.9.17.

(A) By various methods, such as treatment with alkalis and then acids, or *vice versa*, followed by digestion in a closed vessel with a solution of a neutral salt, a kind of half cellulose can be obtained from wood. Wooden logs and planks thus treated may then be mechanically disintegrated in a moist state, and further treated to obtain textile fibres. If heated under pressure these are especially strong and light coloured. (B) Pieces of wood not thicker than 1 mm. can be used instead of logs, and the chemical treatment is omitted. (C) The treatment of the wood before digestion can be varied. The acid and alkali treatment may be replaced wholly or partly by treatment with hydrocarbons, such as benzol, petroleum, naphtha, and gasoline, or by solutions of sodium sulphite, sodium chloride, magnesium sulphate, etc., which do not readily dissolve lignin. The wood may be first heated with alkalis and then treated with argillaceous earth in acetic or sulphuric acid. After one or other of the various treatments above mentioned the wood may be impregnated with oils and fats or solutions of metallic salts etc. (D) The bark bast of coniferous woods can be treated by the methods described under (B) or (C) or by gentle heating with dilute acid or alkaline solutions, and is dried, moistened or oiled, and then carded. Bast fibres may also be obtained from branches. The carding operation demands that the fibres be evenly moistened or oiled to prevent breakage. Bast fibres are finer than those from the wood itself.—A. J. H.

Textile fibres; Obtaining — from woody vegetable substances, such as nettle stalks, barks, etc. A. Hammer. G.P. 312,730, 19.11.15.

TO remove gummy substances and separate the fibres from the wood the nettle stalks or the like are treated with a malt solution, then fermented, boiled with alkali solution, and, finally, subjected to mechanical treatment.—W. P. S.

Wool and artificial wool fabrics; Production of durable —. M. Becke. G.P. 317,725, 21.12.16. Conv., 14.6.16.

IF in the treatment of wool the use of mineral acids and of salts capable of liberating such acids is avoided, the resulting fibres are much more durable, compact, and elastic, and more resistant to alkalis. The removal of burs and coarse plant particles from wool should be done by mechanical means. In the subsequent dyeing only weak organic acids and their salts are used.—A. J. H.

Balloon-fabrics and the like. C. Cleghorn, and The Gayner Pneumatic Co., Ltd. E.P. 142,160, 27.11.18.

A FABRIC impervious to gases such as hydrogen is composed of two sheets of fabric. The face of one sheet may be bare (if it constitutes the interior face of the balloon), and the other is coated with rubber. The second sheet has one face treated with an alcoholic solution of Turkish bird-lime (E.P. 130,379; J., 1919, 730 A), and the other is rubber-coated. The rubber-coated face of the first sheet is placed in contact with the face of the second sheet treated with bird-lime.—A. J. H.

Boiling indirectly; Method of —. [Sulphite-cellulose manufacture.] R. H. Hult. U.S.P. 1,337,701, 20.4.20. Appl., 24.10.17.

THE liquid is first heated by means of heating elements, such as steam coils, which are connected in parallel, and the heating then continued by means of the same or other elements connected in series. In the case of boiling the lye in the sulphite process of manufacturing cellulose the heating elements are connected in parallel until the temperature of the liquid has reached 100°–105° C., and then in series till the temperature reaches about 138° C.—B. M. V.

Acetylcellulose and process of making same. W. G. Lindsay, Assr. to The Celluloid Company. U.S.P. 1,338,661, 27.4.20. Appl., 9.4.18.

CELLULOSE is impregnated with benzene and alcohol and then acetylated with a mixture of acetic anhydride and benzene.—A. J. H.

Gutta-percha substitute from acetylcellulose; Preparation of a — resistant to alcohol. O. Skaller. G.P. 317,145, 13.11.18.

IF a film obtained from acetylcellulose solutions be immersed for a short time in concentrated alcohol, and then dried in air, it becomes quite insensitive to alcohol.—A. J. H.

Fireproofing composition and process of making the same. T. B. Munroe, Assr. to B. Q. Dahlberg. U.S.P. 1,338,322, 27.4.20. Appl., 28.8.19.

ZINC chloride is dissolved in excess of ammonia, and the free ammonia is neutralised by the addition of a substance capable of forming therewith a fire-resisting compound.—A. J. H.

Yarns or fabrics; Method of impregnating textile or paper —. Deutsche Pyroxitges. m.b.H. G.P. 312,686, 4.7.18.

THE yarn etc. is impregnated with wood tar and then dusted over with zinc oxide; the latter combines rapidly with the tar and forms a dry, wax-like mass.—W. P. S.

Cellulose waste lyes; Dry distillation of concentrated —. W. Schacht. G.P. 301,684, 27.8.16.

CONCENTRATED cellulose waste lyes are distilled in a current of an inert gas or steam or a mixture of both. The residue in the retort is then made alkaline and further distilled. From 100 pts. of cellulose lye pitch (sp. gr. 1.5), 50 l. of an aqueous distillate containing ammonia, alcohols, and oils was obtained. On the addition of alkali and further distillation there was obtained 2–4 kg. of oil of sp. gr. 0.930, which yielded about 25% of a good burning oil, sp. gr. 0.800–0.815, and various pyridine bases.—A. J. H.

Drying varnished or gummed sheets of paper and the like; Machines for —. E. and H. Bush. E.P. 141,997, 13.8.19.

Paper-making [machine]. C. E. Pope, Assr. to Great Northern Paper Co. U.S.P. 1,338,091, 27.4.20. Appl., 25.10.18.

Cellulose acetate; Manufacture of solutions of — and of celluloid-like masses, films, and other products therewith. H. Dreyfus. E.P. 128,215, 10.6.19. Conv., 4.3.14.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Steaming fabrics; Apparatus for —. J. Grasser. E.P. 138,637, 4.2.20. Conv., 4.2.19.

A CHAMBER of masonry is divided by a partition having an opening through which the fabric can be raised from the lower chamber to the upper one, which constitutes the real steaming chamber. Steam is introduced at the top of the steaming chamber and is evenly distributed so that all the air is expelled through the partition as the steam fills the chamber. The fabric, wound on a framework, is introduced into the lower chamber, and when the air in the top chamber is expelled is raised through the partition. After steaming, the material is lowered and removed from the lower chamber. The apparatus can be used with advantage for discharging with hydrosulphites.—A. J. H.

Coating process. W. Alexander. U.S.P. 1,337,380, 20.4.20. Appl., 20.10.15.

A FIBROUS surface is coated with an adhesive solution of a water-soluble salt of a base metal capable of readily forming sulphides, such salt being then caused to react with a sulphur-containing substance whereby a decorative coating is produced.

—A. de W.

Dyeing, washing, and similarly treating yarn in the form of hanks, skeins, or the like. J. Annick. U.S.P. 1,337,877, 20.4.20. Appl., 2.9.19.

COMPRESSED yarn is allowed to expand in and completely fill a dyeing chamber. A dye solution is forced through the material, which is then washed and freed from liquid by applying vacuum to one end of the chamber.—A. J. H.

Textiles; Dressing, printing, and dyeing —. F. Günther. G.P. 318,509, 20.6.14.

WATER-SOLUBLE phenol-formaldehyde condensation products, either alone or mixed with cellulose derivatives, such as cellulose esters, nitrocellulose, acetylcellulose, or viscose, and/or thickeners, are employed as textile dressings for fixing metal powders, pigments, or dyes. The condensation products are subsequently hardened by heating. The addition of a cellulose derivative increases the elasticity of the condensation product.—L. A. C.

Dyeing or otherwise treating textile fabrics; Apparatus for use in processes for —. Färberei Weidmann A.-G. E.P. 129,975, 3.7.19. Conv., 18.7.18.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitric acid; War experiences in the manufacture of — and the recovery of nitrous fumes. J. Walker. Chem. Soc. Trans., 1920, 117, 382–389.

AT H.M. Factory, Craigleith, the catalytic oxidation of ammonia to nitric oxide was effected by leading an ammonia-air mixture containing 10–12% NH₃ through a glass or slag wool filter to a platinum gauze catalyst placed horizontally across an aluminium box. The gases emerging from the converter were cooled and led through oxidation and absorption towers, the last traces of nitric acid

being removed by wash towers fed with milk of lime. The recovery of nitric acid and nitrous gases from the waste acid of T.N.T. manufacture was effected in denitrators of acid-resisting brick, square in section, and divided into six compartments by finely perforated earthenware plates (malting plates). Steam was blown in at the base and waste acid fed in at the top. The denitrated acid removed at the base was passed to sulphuric acid concentrators, and the gases from the denitrators, after passing through cooling coils which condensed out a dilute nitric acid, were led through a series of six recovery towers 90 cm. in diameter and 5 m. high, worked on the counter-current principle, the nearly exhausted gas coming into contact in the last tower with the dilute nitric acid from the denitrator condensers. The recovery by this system was more than 93% of the inorganic nitrogen delivered to the denitrators in the waste acid.

—G. F. M.

Sodium nitrate; Determination of nitrogen in — by the modified Devarda method and the use of the Darvison scrubber bulb. C. A. Butt. *J. Ind. Eng. Chem.*, 1920, 12, 352—354.

THE modified Devarda method (Allen, J., 1915, 726) yields accurate and concordant results, particularly when the Darvison scrubber bulb (J., 1919, 443 A) is used to prevent alkali spray passing over into the absorption vessel.—W. P. S.

Nitrite+nitrate+nitric oxide; Electrolytic potential of the change —. Energy relationships of the most important compounds of nitrogen with oxygen and hydrogen. H. Pick. *Z. Elektrochem.*, 1920, 26, 182—196.

THE normal potential of the change $2\text{NO}_2' + \text{NO}_3' + \text{NO}$ is +0.49 volt at 25° C. A series of normal potentials are given for N_2 , N_2O , NH_3 , NH_4 , NO_2 , and N_2O_4 . (Cf. J.C.S., July.)—J. F. S.

Iodide and bromide in mineral waters and brines; Determination of —. W. F. Baughman and W. W. Skinner. *J. Ind. Eng. Chem.*, 1920, 12, 358.

A COMBINATION of two methods described previously by the authors (J., 1919, 498 A; 1920, 19 A) is recommended. After the iodine has been removed by distillation with ferric sulphate, the residual solution is treated with a slight excess of ammonia, boiled, the ferric hydroxide separated by filtration, the filtrate evaporated to dryness, and the residue thus obtained used for the determination of the bromide.—W. P. S.

Potassium bromide; Solubility of — in bromine water. A. F. Joseph. *Chem. Soc. Trans.*, 1920, 117, 377—381.

THE solubility of potassium bromide in water is increased by the addition of bromine; for moderate concentrations about 0.5 grm.-mol. additional bromide is dissolved for each grm.-mol. of bromine added to the water. The limit of the solvent capacity of the water was not reached at bromine concentrations of more than 2060 g. per litre of solution, for example with a solution of the composition by weight—water 5.4%, bromide 15.1%, bromine 79.5.—G. F. M.

Potassium ferriocyanide; Electrolytic preparation of —. O. W. Brown, C. O. Henke, and I. L. Miller. *J. Phys. Chem.*, 1920, 24, 230—237.

THE maximum yield obtainable in the electrolytic oxidation of potassium ferrocyanide in an undivided cell was 50%. When a diaphragm was used with a current of 0.90 amp. caustic potash was found in both compartments of the cell and a current efficiency of about 98% was obtained. The presence of potassium hydroxide increased the current effi-

ciency and decreased the voltage slightly. All the ferrocyanide decomposed was not converted into ferriocyanide. Electrodes of different materials gave different current efficiencies, and in all cases the maximum efficiency was not reached until the electrolysis had been in progress for 4 hrs. The following maximum current efficiencies were obtained working with an anode $7\frac{1}{2} \times 11\frac{1}{2}$ cm. and a current of 0.95 amp.: copper 96.3%, nickel 97.7%, platinum 96.6%, Acheson graphite 99.7%, and lead covered with lead dioxide 93%.—J. F. S.

Slaked lime and milk of lime. B. Kosmann. *Z. Elektrochem.*, 1920, 26, 173—181.

THE views of Kohlschütter and Walther (J., 1920, 25 A) are criticised. The author holds the view that the slaking of lime consists in a gradual step-wise combination with water in which the following substances are produced in order: $\text{Ca}(\text{OH})_2$, $\text{H}_2\text{Ca}(\text{OH})_4$, $\text{H}_2\text{Ca}(\text{OH})_6$, $\text{H}_2\text{Ca}(\text{OH})_8$, $\text{H}_2\text{Ca}(\text{OH})_{10}$, $\text{H}_2\text{Ca}(\text{OH})_{12}$, and $\text{H}_2\text{Ca}(\text{OH})_{14}$.—J. F. S.

Alum; Rapid estimation of aluminium sulphate in —. P. W. Codwise. Paper, 1920, 26, 187—189.

THE method is based on the reaction: $\text{Al}_2(\text{SO}_4)_3 + 6\text{NaOH} = 2\text{Al}(\text{OH})_3 + 3\text{Na}_2\text{SO}_4$. A quantity of alum or aluminium sulphate equivalent to about 40 c.c. of N/10 caustic soda solution is dissolved in exactly 25 c.c. of distilled water, the solution heated to the boil and one drop of a 1% alcoholic solution of phenolphthalein added. Three successive quantities of 10 c.c. of N/10 caustic soda are added, and the liquid heated to boiling for exactly 1 min. after each addition, and then the caustic soda is added gradually until a slight pink tinge is produced and persists after boiling for 1 min. If the sample contains free acid, this must be determined and allowed for. If the above procedure be followed exactly, the results agree within 0.1%. The method only measures combined alumina, so that with basic alums the results are low. The presence of iron impurities does not affect the results.

—A. J. H.

Radium and mesothorium; Concentration of — by fractional crystallisation. J. L. Nierman. *J. Phys. Chem.*, 1920, 24, 192—200.

THE crystallisation factor (concentration of mesothorium in crystals separated: concentration in original crystals) of mixtures of barium, radium, and mesothorium bromides is independent of the concentration of the hydrobromic acid from which crystallisation takes place. The value of the crystallisation factor decreases with increasing percentage of separation: thus when 24.3% of the salt crystallises the factor is 2.43, and when 69% crystallises 1.44. For concentrations of mesothorium up to 2 mg. per 1 g. of salt the crystallisation factor remains constant. The separation of radium and mesothorium from barium can be advantageously carried out in either neutral or slightly acid solutions.—J. F. S.

Hydrogen peroxide; Activation of — by light. H. A. Curtis. *J. Amer. Chem. Soc.*, 1920, 42, 720—724.

SOLUTIONS of Aniline Green and fuchsine are not decolorised by 3% hydrogen peroxide, nor are they bleached by light of short wave lengths, but if a mixture of the dye solutions and 3% hydrogen peroxide is exposed to the light from a quartz mercury lamp the solution is bleached rapidly. Bubbling oxygen through the dye solution during illumination does not effect bleaching.—J. F. S.

Catalytic actions at solid surfaces. II'. Interaction of carbon monoxide and steam as conditioned by iron oxide and by copper. E. F. Armstrong and T. P. Hilditch. *Proc. Roy. Soc.*, 1920, A, 97, 265—273.

At high temperatures copper influences the reaction

$\text{CO} + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + \text{H}_2$ much less than iron oxide, but over the range $200^\circ\text{--}300^\circ\text{C}$. copper is definitely more active than iron oxide. Copper commences to react with a fair velocity at 220°C ., whereas iron oxide is only slightly active at 250°C . and does not reach full activity until 400°C . Small quantities of ammonium formate are produced when water-gas (5.1 CO_2 , 39.9 CO , and 47.3 H_2) with steam in the presence of ammonium is passed through a tube at 350°C . (Cf. J.C.S., July.)

—J. F. S.

Sulphur; Determination of minute quantities of "oil" in —. L. S. Bushnell and H. S. Clark. J. Ind. Eng. Chem., 1920, 12, 485.

ABOUT 50 g. of the pulverised sulphur is shaken at intervals with 50 c.c. of petroleum spirit, and after some hours the extract is decanted through a filter into the tube of a Wiley continuous extractor, into which is introduced a clean dry coil of copper foil, 4 in. by 15 in., rolled up so that no points of its surface are in contact. The residue in the flask and the filter are washed with petroleum spirit (about 175 c.c. in all) until the washings are sufficient to fill the Wiley tube. The extract is then boiled until the whole of the dissolved sulphur has been deposited as copper sulphide upon the coil, after which it is filtered and evaporated to dryness at a low temperature, and the residue of "oil" weighed.—C. A. M.

Sorption of vapours by charcoal. B. Gustafson. Ark. Kemi, 1917, 7, No. 22, 1–17.

CHARCOAL takes up water vapour and acetic acid vapour at low pressures (1.6–17.4 mm.) proportionally with the pressure. Up to a pressure of 7.4 mm. the sorption process consists in the formation of a solid solution, and above this pressure simple absorption occurs. The velocity of sorption is greater the lower the pressure. (Cf. J.C.S., July.)—J. F. S.

Acetates. Curtman and others. See XX.

Calcium, strontium, and barium salts. Denigès. See XXIII.

PATENTS.

Nitric and sulphuric acid; Process of concentrating —. A. C. Bohre. U.S.P. 1,338,418, 27.4.20. Appl., 28.7.19.

HOT nitrous gases are brought in contact with nitric or sulphuric acid to be concentrated, the resulting vapours are condensed by contact with a cooling liquid, and the cooling liquid is then cooled for condensing further quantities of the vapours by passing a gas through it.—L. A. C.

Nitric acid; Manufacture of — by catalytic oxidation. A. Maschke. G.P. 307,052, 10.11.17.

THE gases obtained by heating ammonium bisulphate or ammonium sulphate are mixed with air and substituted for ammonia in the catalytic process. The resulting vapours may be cooled, yielding a mixture of nitric and sulphuric acids suitable for nitration purposes, or dilute sulphuric acid and highly concentrated nitric acid may be obtained by cooling in stages.—W. J. W.

Nitrous gases; Process for rapid cooling of — obtained by combustion of nitrogen. R. Mewes. G.P. 316,214, 25.4.15. Addition to 298,846.

THE electrically-heated gas mixture under high pressure, containing the nitrous gases which have been formed, is mixed with air at an equal or higher pressure and previously cooled or liquefied, after

which the mixture is allowed to pass into an expansion chamber. After absorption of the nitrous gases the residual mixture is returned to the system.

—W. J. W.

Nitric oxide; Method of working gas engines for producing —. J. Goring, G.P. 316,253, 6.4.19.

A MIXTURE of coal gas and producer gas is used as fuel. The coal gas should preferably contain 40–50 H_2 and have a calorific value of 4000–5000 cals. per cb. ft., but good results are obtained so long as the calorific value does not fall below 2000 cals. per cb. ft., provided the ratio of hydrogen content to calorific value is about 10 H_2 per 1000 cals.

Sulphate of ammonia; Manufacture of —. S. E. Linder and R. Lessing. E.P. 141,787, 18.1.19.

COMMERCIAL ammonium sulphate is treated with lime, magnesia, or other alkaline earths or their carbonates, or with suitable ammonium salts such as the sulphide, sulphate, or carbonate, applied in the solid state or in solution, to neutralise the free acid. The sulphate is treated with one of the above agents or with gaseous ammonia in some form of heated disintegrating chamber, the treated material forming a dry granular or pulverulent product. If the treatment is effected in a partial vacuum or in a current of air or other gas, the pyridine normally present in the crude sulphate is wholly removed and recoverable.—D. F. T.

Ammonium sulphate; Manufacture of —. South Metropolitan Gas Co., E. V. Evans, and H. Hollings. E.P. 141,798, 20.1.19.

CAKING of ammonium sulphate may be avoided by neutralisation of the free acid present in the crystals, followed by drying at an elevated temperature such as $80^\circ\text{--}100^\circ\text{C}$.—D. F. T.

Sulphate of ammonia; Manufacture of —. South Metropolitan Gas Co., and O. W. Wright. E.P. 141,799, 20.1.19.

THE free acid in crude ammonium sulphate is neutralised by mixing with solid or dissolved ammonium sulphite or bisulphite, or by the addition of either of these substances to the liquor used for washing the ammonium sulphate crystals. Any small excess of sulphite finally undergoes natural oxidation to sulphate.—D. F. T.

Sulphate of ammonia; Manufacture of neutral —. South Metropolitan Gas Co., P. Parrish, and W. A. M. Valon. E.P. 141,819, 23.1.19.

FOR neutralising ammonium sulphate crystals aqueous ammonia is prepared by condensing the vapours of the "fixed ammonia" still and diluting the resulting solution so that its vapour pressure at the temperature of application to the crystals will be too low to entail substantial loss of ammonia. The temperature of washing should be as low as possible, because both the reduced temperature and the use of more concentrated solutions of ammonia tend to decrease the loss of ammonium sulphate during the operation. A particularly suitable diluent for the condensed vapours is produced by subjecting the hot waste liquor of the fixed ammonia still to a slightly reduced pressure, the condensed liquid thus obtained containing a considerable portion of the residual ammonia which would otherwise be lost.—D. F. T.

Ammonium sulphate; Production of — from distillation gases by means of sodium bisulphate. P. von der Forst. G.P. 298,012, 8.3.16.

A SATURATED or nearly saturated hot solution of sodium bisulphate is neutralised with the ammoniacal gases so that Glauber's salt separates. By evaporation and crystallisation of the remaining

solution ammonium sulphate is obtained, or the solution may be added to the sulphuric acid fed to a saturator of the usual type.—E. H. R.

Ammonium sulphate; Reaction tower for conversion of ammonium carbonate into — by means of calcium sulphate. C. Otto und Co. G.P. 299,621, 18.2.16.

In the manufacture of ammonium sulphate by treatment of ammonium carbonate with plaster of Paris paste, sodium chloride may be added to increase the solubility of the calcium sulphate. The paste is of such a concentration as to retain a large amount of the ammonium sulphate produced. By mixing steam with the ammonia and carbon dioxide vapours a suitable temperature is maintained, and the liquors will be free from ammonia. The conversion may be carried out in a reaction-tower comprising a top section with inlet for the plaster of Paris paste and exit for gases, and a bottom section with steam inlet and run-off for the paste. The tower is packed with a number of rings, each of which forms a receptacle in which the reacting liquids can remain sufficiently long to ensure complete conversion, an additional, smaller cup in the ring serving for the introduction of steam into the liquid. Scrapers, connected to a central shaft, operate in the cups and receptacles.—W. J. W.

Ammonia; Process of manufacturing — from crude calcium cyanamide. C. Otto und Co. G.P. 303,842, 28.3.16.

By the use of the reaction-tower described in G.P. 299,621 (preceding abstract), the formation of lime crusts is prevented. The ring receptacles are of such dimensions as to admit of the calcium cyanamide mud remaining in the tower about four times as long as in other processes.—W. J. W.

Ammonium chloride; Manufacture of — from ammonia and alkali or alkaline-earth chlorides. Salzwerke Heilbronn, A.-G. G.P. 306,351, 5.10.16.

CHLORIDES are melted, or heated above 150° C., and treated with ammonia or ammoniacal gases in presence of steam. Treatment with steam may precede the interaction with ammonia. Carbon dioxide may be introduced into the process, and substances such as iron oxide, clay, etc. may be added to accelerate the reaction. By conducting the conversion in a reducing atmosphere side-reactions, such as combustion of the ammonia, are avoided.—W. J. W.

Halogen compounds of silicon, boron, or titanium; Production of fluid —. British Thomson-Houston Co. From General Electric Co. E.P. 141,908, 23.4.19.

THE formation of undesirable solid by-products on account of undue liberation of heat during the interaction of chlorine or bromine and silicon, boron, or titanium or suitable derivatives of these, such as their carbides, is obviated by circulating water around the reaction chamber so as to maintain the temperature below the point at which such by-products are liable to be produced.—D. F. T.

Barium carbonate; Manufacture of finely sub-divided —. H. Langwell. E.P. 141,925, 10.5.19.

FINELY sub-divided barium carbonate is obtained by heating the natural or artificial material with sodium chloride; the fused salt dissolves approximately twice its weight of the carbonate, and impurities separate as a sediment or scum. The molten mass is then treated with water and the barium carbonate collected.—D. F. T.

Caustic soda; Apparatus for the manufacture of "detached" or flake — or other matter required to be obtained in a state of division from a fused or molten mass. T. Minton, and The United Alkali Co., Ltd. E.P. 141,942, 23.5.19.

MOLTEN material such as sodium hydroxide or the

like is fed into a rotating, circular, open pan, water-cooled from underneath. A stationary scraper is fixed along a radius of the pan, and a ribbed or toothed roller rotates above the scraper so that the material separated from the pan by the scraper is broken up into flakes. A rotating brush sweeps the flaked material up an inclined plane, also radially disposed, on to a trough, whence it is removed by an endless chain conveyor.—L. A. C.

Tin; Methods and apparatus for the oxidation of — and the production of tin oxide, and for the treatment of zinc and zinc-containing materials for the production of zinc oxide. H. Maconochie and D. de Ros. E.P. 142,157, 30.10.18.

As an improvement in the processes described in E.P. 118,664 and 118,665 (J., 1918, 622 A), tin (or zinc) is preheated to about 900° C. by an oil burner, and the temperature is then allowed to rise to 1500°–1700° C. by the application of a high-pressure air-blast (i.e., about 4–5 lb. per sq. in.) with the production of tin (or zinc) oxide, which is removed. Completion of the oxidation is effected by means of a low-pressure blast (i.e., about 0.15–0.5 lb. per sq. in.), and the temperature may be maintained by the addition of the necessary amount of oil to the blast. Different types of furnace suitable for the process are described.—L. A. C.

Alkali chromates; Process for isolating or purifying —. Soc. Ind. des Prod. Chim. E.P. 138,111, 25.1.18. Conv., 2.8.17.

A CONCENTRATED solution of crude alkali chromates containing only a small percentage of alkali hydroxides is treated with carbon dioxide whereby silicates and aluminates are converted to silica and alumina, and alkali hydroxides to bicarbonates; the solution is then filtered and evaporated to crystallise pure alkali chromates. The dry crude chromates may be treated with carbon dioxide, and the product extracted with a little water.—L. A. C.

[Alkali] manganates; Process of making —. H. McCormack, Assr. to Research Laboratory of Chicago. U.S.P. 1,337,239, 20.4.20. Appl., 6.1.19.

A MIXTURE of manganese dioxide and an aqueous solution of an alkali hydroxide is evaporated to dryness and heated to complete the reaction; the product is extracted with water, and, after separation of insoluble matter, the clear solution is cooled to crystallise the manganate.—L. A. C.

[Alkali] manganates; Process of making —. C. E. Vanderkleed, Assr. to Hercules Powder Co. U.S.P. 1,339,242, 4.5.20. Appl., 21.11.18.

MANGANESE dioxide and sodium peroxide are fused together to form sodium manganate.—L. A. C.

Potassium salts; Recovery of —. P. C. McIlhiney, Assr. to California Alkali Co. U.S.P. 1,338,234 and 1,338,235, 27.4.20. Appl., 11.2.18.

COMMERCIAL pure potassium salts, e.g., the chlorate, may be obtained from natural brines containing potassium salts associated with borax by the addition of a soluble salt of which the acid radical forms an insoluble potassium salt, e.g., a chlorate, and removing the insoluble potassium salt from the solution.—J. H. J.

Potash salts; Process for increasing the potash content of crude —. J. Kiermayer, and Hannoversche Kaliwerke A.-G. G.P. 317,771, 21.11.15.

AFTER melting and removing the impurities, the potash salts are treated with reducing agents, by which means the magnesium sulphate is converted into magnesite and sulphur compounds. Coke and charcoal are suitable agents; coal gives unstable by-products. By this treatment the potash content of a mineral of the composition K₂O, 8.5%; kieserite, 25%; NaCl, 50%; and clay etc., 5.5%, was increased to 12% K₂O.—W. J. W.

Crystallisation of solutions, especially of potassium salts; Process for —. G. Sauerbrey. G.P. 318,350, 30.10.18.

The solution to be crystallised is conveyed by a pipe to the centre of a flat plate, which may have a rim, and which revolves round a vertical axis. The plate may be revolved continuously or intermittently to enable the crystals to be removed, and its speed may be controlled.—W. J. W.

Radium; Producing compounds of —. H. O. Hedström. U.S.P. 1,338,831, 4.5.20. Appl., 31.10.19.

RADIUM is extracted from minerals etc. by treatment with liquid sulphur dioxide containing sulphur trioxide. (Cf. E.P. 136,768 of 1919; J., 1920, 156 A.)—W. E. F. P.

Alkali nitrates; Manufacture of — from mixtures of nitric acid and water, and alkali sulphates. E. Reinau. G.P. (A) 299,001, 1.2.16; (b) 299,002, 25.3.16; (c) 299,003, 23.6.16; (d) 299,006, 25.3.16; and (e) 299,007, 17.2.16.

(A) THE materials are caused to react, under influence of heat, in such proportions as to convert the sulphate into bisulphate. The mixture is then cooled if necessary, and the solid portion consisting chiefly of alkali nitrate is separated from the liquid mixture of water, alkali nitrate, sulphate, bisulphate, and free acid. The solid portion may be mixed with a fresh quantity of nitric acid and water. Instead of nitric acid and water a mixture of water and two or more of the following components may be employed:—alkali nitrate, sulphate, bisulphate, nitric acid, and sulphuric acid. The cooling of the reaction mixture, during separation of the solid portions, may be intermittent. 50% of the combined nitric acid may be recovered as 92–95% alkali nitrate under suitable conditions of temperature and concentration. (u) Mixtures of various alkali sulphates, with or without hydroxides, may be used. (c) The process, or certain phases of it, may be carried out under other than atmospheric pressure, loss of nitric acid on evaporation being thus avoided. (d) Alkali magnesium sulphates, or mixtures of alkali and magnesium sulphates, or hydroxides, may be employed. (e) The liquid portions consisting of mother liquor and wash-waters may be freed from uncombined nitric acid by distillation, and the condensed acid mixed with fresh nitric acid and used again. The residue after distillation consisting of alkali sulphate and bisulphate is also available for the process.—W. J. W.

Alkali nitrates and hydrochloric acid; Manufacture of — from mixtures of nitric acid and water, and alkali chlorides. E. Reinau. G.P. (A) 299,004, 17.2.16, and (n) 299,005, 25.3.16. Addns. to 299,001 (preceding).

(A) By the interaction of nitric acid, water, and alkali sulphate, alkali bisulphate is obtained, which is then caused to react with alkali chloride, with or without addition of alkali sulphate, to form hydrochloric acid. The alkali sulphate required for the process is prepared by treatment of an alkali compound with alkali bisulphate, polysulphate, or free sulphuric acid, or another sulphate. (n) Mixtures of alkali sulphates with or without alkali chlorides, and with or without hydroxides, may be employed.—W. J. W.

Alkali nitrates and ammonium sulphate; Manufacture of — from mixtures of nitric acid and water, alkali sulphate, and ammonia. E. Reinau. G.P. 305,062. 1.4.17. Addn. to 299,001 (preceding).

IN the first stage, by the action of water and nitric acid on alkali sulphate, part of the alkali is separated as alkali nitrate, while the combined sulphuric

acid and acid alkali sulphate remain. In the second stage the acid alkali sulphate is treated with water and gaseous ammonia, causing separation of alkali nitrate and solution of alkali-ammonium sulphate, from which a high percentage of ammonium sulphate may be recovered. The alkali sulphate recovered in this second stage is available for use in the first stage.—W. J. W.

Liquors containing calcium sulphate; Treatment of —. G. Sauerbrey. G.P. 318,310, 15.4.19.

THE liquors are treated with magnesium chloride, the precipitated chlorides of potassium and sodium being removed, and the liquors then evaporated by the action of furnace gases. A further quantity of salts may be separated by cooling the solution before evaporation.—W. J. W.

Argon; Production of —. G. A. Percival, and The Edison Swan Electric Co., Ltd. E.P. 141,783, 9.1.19.

ARGON is separated from air by circulating the air through a heated tube fitted with a worm conveyor, by means of which an absorbent for oxygen and nitrogen, e.g., calcium, is passed through the tube in a direction opposite to that of the air. Air-tight charging and discharging devices, consisting of chambers with double doors, are attached to the ends of the tubes, and an "ometer" for collecting the argon is provided in the air-circulating system.—L. A. C.

Air; Method of and apparatus for fractionating —. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 141,864, 14.3.19.

OXYGEN, nitrogen, and an argon concentrate are obtained from liquid air by fractionation in a rectifying column having an inlet for liquid air and an outlet for distillate near the top, and means for collecting liquid gas (largely oxygen) at the bottom. The distillate withdrawn from the upper part of this column is liquefied and subsequently treated in a second column to produce gaseous nitrogen and a liquid consisting largely of oxygen and argon.—W. E. F. P.

Oxygen concentrator. G. McKerahan. U.S.P. 1,339,211, 4.5.20. Appl., 27.1.20.

A CIRCULAR (disc-shaped) vessel, mounted to rotate about a horizontal axis, has on one side an air inlet around the axis and, on the opposite side, an outlet situated between the axis and the periphery and concentric with the latter. A second outlet is disposed around the extreme periphery of the vessel.—W. E. F. P.

Chlorine liquefaction; Process of —. C. T. Henderson, Assr. to Niagara Smelting Corp. U.S.P. 1,338,654, 27.4.20. Appl., 10.2.17.

CHLORINE is dissolved in carbon tetrachloride and then expelled from the solution into a condenser, the gas being liquefied by the pressure thus produced.—W. E. F. P.

Hydrogen or nitrogen; [Catalytic] production of —. F. Lang. G.P. 307,651, 24.9.16.

A CONTACT chamber for catalytic production of hydrogen or nitrogen by the alternate passage of steam or air and reducing gases over a contact substance comprises a cylindrical outer shell with permeable walls and gas and steam distributing compartments, and an inner permeable wall forming a tubular distributing chamber for the steam and gases. The contact chamber may have internal projecting pieces and partitions. It may be divided into upper and lower compartments, communicating by means of tubes, and connected to common inlets and exits. Low yields in the process are ascribed to the influence of reverse reactions, which increase in proportion to the height of the contact chamber.—W. J. W.

Nitric acid and tetroxide of nitrogen; Production of pure concentrated —. Norsk Hydro-Elektrisk Kvaestofaktieselskab. E.P. 124,191, 4.2.19. Conv., 13.3.18.

SEE U.S.P. 1,324,255 of 1919; J., 1920, 108 A.

Nitric acid; Manufacture of concentrated —. E. Bergey and O. Jensen, Assrs. to Norsk Hydro-Elektrisk Kvaestofaktieselskab. U.S.P. 1,338,417, 27.4.20. Appl., 30.9.18.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass; Manufacture of —. E. H. Langwell. E.P. 142,365, 9.7.19.

AN outlet for molten glass in a glass furnace is provided with several nozzles made of steel and lined with refractory material, and is rotated so that each nozzle is used in turn. After a nozzle has been used it is heated and all adherent glass is removed, so as to avoid the production of defects or marks in the glass.—A. B. S.

Plastic masses and new industrial products obtained therefrom; Manufacture of —. L. Gauthier. E.P. 128,905, 15.5.19. Conv., 22.6.18.

A PLASTIC mass is made by incorporating 70–90% of tale, with or without the addition of 2% of zinc white, in 30–10% of gelatin which has previously been allowed to swell in water and then melted, the mixture being stirred until it thickens. The paste is made into cakes and stored in a damp cloth. It may be moulded under pressure, and after drying in air for 8–10 days may be treated with formaldehyde and varnished or soaked in water-glass. The product may be used as a substitute for porcelain in the manufacture of electrical insulators etc.—A. B. S.

Plastic compositions. L. Deleglise. E.P. 141,987, 29.7.19.

A MIXTURE of 25 parts of fibres of wood, paper, rags, or the like, and 175 parts of plaster is kneaded, heated to 50°–80° C., incorporated with a mixture of a solution of 45 parts of gelatin (glue) containing 10 parts of tin dioxide and 110 parts of water at the same temperature, and the mixture kneaded and heated with 35 parts of a 14% aqueous solution of formalin or sodium bichromate.

—A. B. S.

Brick kilns. A. Sharratt. E.P. 142,237, 4.3.19.

IN a continuous kiln or series of intermittent kilns, instead of the usual metal or paper dampers closing the trace holes or passages between each chamber, a wall of coke is used which filters the gases and so prevents them damaging the goods. When the firing has proceeded sufficiently, the coke is ignited and eventually burns away.—A. B. S.

China clay; Drying —. J. Adair. E.P. 142,161, 16.12.18 and 8.1.19.

CHINA clay slurry is discharged through the sloping bottom of the settling tanks into a belt elevator and thence on to fixed aluminium trays, the bottoms of which may be either flat or corrugated. The trays are in two series, the upper ones being fixed and the lower ones mounted on wheels so that they may be run into a rectangular drying chamber heated by gas burners or electric radiators arranged in parallel lines and mounted to move reciprocally and so ensure uniform heating. The dried clay is discharged by releasing the hinged sides of the trays and tilting the latter.—A. B. S.

Clay ware; Method and apparatus [tunnel kiln] for burning —. C. B. Harrop. U.S.P. 1,338,771, 4.5.20. Appl., 13.6.19.

THE ware is burned in a tunnel kiln having "staggered" clearance spaces in its walls, these spaces increasing towards the bottom of the setting of ware. The upper portion of the setting of ware is placed in such a manner that the gases will pass downwards through the setting to the lower parts of the clearance spaces.—A. B. S.

Abrasive structures; Method of making —. C. W. Thomas. U.S.P. 1,338,598, 27.4.20. Appl., 24.7.16.

ABRASIVE grains are mixed with a temporary binder and a permanent binder composed of pre-shrunk vitreous material. The mixture is moulded and then fired at a temperature sufficiently high to fuse the vitreous binder.—A. B. S.

Aluminous [abrasive] composition and method of making the same. O. Hutchins, Assr. to The Carborundum Co. U.S.P. 1,339,344, 4.5.20. Appl., 18.9.19.

AN aluminous abrasive is made by fusing in an electric furnace a mixture of an aluminous material and a strontium compound which yields strontium oxide.—A. B. S.

Graphite articles and method of making the same. S. C. Linbarger, Assr. to The Carborundum Co. U.S.P. 1,339,266, 4.4.20. Appl., 13.12.18.

THE articles are made of particles of graphite coated with a thin film which prevents oxidation.

—A. B. S.

Glass tubes; Manufacture of reinforced —. K. Küppers. E.P. 134,841, 4.11.19. Conv., 13.11.16.

Solid [refractory] bodies from nitrides; Process of making —. E. Podszus, Assr. to The Chemical Foundation, Inc. U.S.P. 1,337,264, 20.4.20. Appl., 21.10.14. Renewed 26.6.19.

IX.—BUILDING MATERIALS.

Cement raw materials; Reactions of — during heating. R. Nacken. Zement, 1920, 9, 61—63, 74—75, 85—89. Chem. Zentr., 1920, 94, II., 591.

On heating Rüdgersdorf raw materials, a strongly exothermic reaction occurs between 1200° and 1300° C., followed by an endothermic reaction accompanied by sintering. With chemically pure materials (free from MgO, SO₃, etc.) the exothermic effect is most strongly marked at 1350° C.

—W. J. W.

PATENTS.

Wood; Process and apparatus for rendering — impermeable and recovering liquids contained therein. C. Roy. E. P. 130,981, 29.7.19. Conv., 3.8.18.

Logs of wood are made impermeable by attaching to them a head and injecting water at a suitable temperature followed by an aqueous solution of casein and ammonia containing lime so as to replace the sap. The logs are then cut into planks and dried in a hot chamber so as to precipitate the casein. The treated timber is resistant to the action of heat, moisture, and light; it does not warp and may be easily glued.—A. B. S.

[Waterproof] construction materials; Process of making —. R. P. Perry, Assr. to The Barrett Co. U.S.P. 1,338,037, 27.4.20. Appl., 8.12.17. Renewed 27.8.19.

A watery pulp of fibrous material is mixed with a large quantity of comminuted fusible waterproofing material, and the mixture is formed into a layer and heated sufficiently to soften the waterproofing material without evaporating the water.—A. B. S.

Ores and iron-making material; Valuation of —. C. H. Ridsdale. Iron and Steel Inst., May, 1920. [Advance proof.] 30 pages.

THE author has collected chemical and thermal

data from the use of which accurate valuations of ores etc. can be made. The type of pig the ore is best adapted to make must be determined and this grade adopted as the basis of valuation. Four examples are given of standard types and grades of pig, with the corresponding basicity of the slag. Ores should be compared on the same basicity of slag. Methods are described for calculating the quantities of ore, limestone, coke, etc., required and slag produced per ton of pig. The requirements of each constituent are calculated by preparing a balance sheet of it and the respective coke multiples obtained. The calculations are made first under ideal conditions and then corrections determined from practical considerations. Startling differences are noticeable in the value of various ores generally regarded as substantially equal, and examples are given showing that iron content is often little guide to value.—T. H. Bu.

Iron ore; Utilisation of titaniferous — in New Zealand. J. A. Heskett. Iron and Steel Inst., May, 1920. [Advance proof.] 14 pages.

THE titaniferous iron sands of New Zealand are low in ferric oxide, and require a greater percentage of direct reduction by carbon than more easily reduced ores. In experimental trials, using a hot blast, a briquetted 8:1 iron-sand-coal mixture was employed. The slags were fluid, but obstructions consisting of a solid mixture of coke and ferro-titanium with entrapped cinder prevented tapping. By tapping at short intervals the front of the hearth was kept clear, but the back side of the hearth became built up. Probably if the high-titanium ores contained sufficient gangue to make a self-fluxing burden, hearth troubles would be eliminated. A satisfactory method would be to mix titaniferous and non-titaniferous ores in proportions adapted to absorb the precipitated titanium-bearing alloy. Pig iron produced from titaniferous ores has a tendency to chill in ordinary sand castings, but is exceptionally strong and tough. The castings have a wonderful finish, but the iron is better adapted to steel production than to ordinary foundry work.

—T. H. Bu.

Grey cast iron of different grades; Strains in —. O. Banse. Stahl u. Eisen, 1919, 39, 313—316, 436—441, 596—600.

THE effect of the grade of the iron and the moisture content of the mould on the appearance of strains in square or round frames of grey cast iron with thin crossbars was determined. The strains produced diminish as the silicon content increases, and are smaller in castings produced in dry moulds than in those made in moulds of "green" sand.

Iron; Defects in electro-deposited —. W. E. Hughes. Iron and Steel Inst., May, 1920. [Advance proof.] 18 pages.

THE defects which may occur in electro-deposited iron include pin-holes, surface roughness, inclusions of foreign matter, and cracks or incipient cracks, especially where different structures meet. Pin-holes are due to the evolution of hydrogen, and are minimised by using low current densities and slowly-formed deposits. Surface roughness is due to suspended matter in the solution or possibly to the solution becoming alkaline around the cathode. The inclusions which may occur in electro-deposited iron are iron oxide, hydrogen, and carbon from the anodes or electrolyte, especially perhaps those containing oxalates. Electrolytic iron could be used to a much greater extent than at present for building up worn parts of machines provided the process were under scientific control.—F. C. Th.

Iron; Effect of various elements on the electrical resistivity of —. A. L. Norbury. Iron and Steel Inst., May, 1920. [Advance proof.] 19 pages.

BENEDICKS' method of plotting the values of the resistivity of quenched carbon steels on a straight line and extrapolating to 7.6 microhms as the value for pure iron cannot be correct. Recent investigations give 9.9 microhms as the resistance of pure iron, and show that equi-atomic solutions of different elements do not give exactly the same resistivity in iron. The electronic properties of the element exert an influence.—F. C. Th.

Iron and mild steel; Microstructure of — at high temperature. H. S. Rawdon and H. Scott. Amer. Inst. Min. Eng., Feb., 1920. Chem. and Met. Eng., 1920, 22, 787—791.

THE microstructure of pure, electrolytic iron (C 0.03%, S 0.002%, Si 0.009%; Ac2 768°, Ac3 910°, Ar2 768°, Ar3 900° C.) was developed by the heat-relief method (heating in vacuo at high temperatures). Specimens of about 3 g. were mounted on the end of a platinum platinum-rhodium thermocouple and heated in a differentially heated, evacuated furnace to 950°, 880°, and 700° C. respectively, the samples being kept at the maximum temperature for 30 mins. and cooled at the rate of 0.15° per sec. The structure is indicated by photographs. A matt surface is sometimes produced by volatilisation, and a roughened surface may be caused by buckling, due to volume change. A low-carbon steel (C 0.18%, Si 0.007%; Ac1 738°, Ac2 769°, Ac3 840°, Ar3 792°, Ar2 769°, Ar1 700° C.) was treated similarly to the iron, the temperatures being 950°, 760°, and 700° C. respectively. A strongly-marked change occurred just above the A1 transformation, diminishing on heating to higher temperatures owing to increased rate of diffusion of carbon. At high temperatures the results obtained by etching are more indicative of the structure of the interior than at temperatures just above A1. Volatilisation of iron from the surface is very slight.—W. J. W.

Steel; Elastic development of —. S. Cornell. Chem. and Met. Eng., 1920, 22, 677—680.

RESULTS are given of the changes in hardness and tensile strength produced by varying the heat treatment of various grades of steel used in the manufacture of rifle components and bayonets. Thus a large number of bayonets which, after being hardened at 1500° F. (820° C.) and drawn at 575° F. (300° C.), had failed to pass the specified mechanical tests, were "stiffened" by re-drawing at 750° F. (400° C.), and then gave satisfactory results. The steel contained about 0.86% C, with Ar 1260° F. (680° C.), and Ac 1335° F. (725° C.).

Steel; Distribution of phosphorus in — between the points Ac1 and Ac3. J. H. Whiteley. Iron and Steel Inst., May, 1920. [Advance proof.] 24 pages.

IN a series of hypoeutectoid steels with the phosphorus varying between 0.006 and 0.12%, heated to and maintained between the Ac1 and Ac3 points, it was found that the phosphorus contained in the γ -iron partly diffuses into the adjacent ferrite owing to its lower solubility in the former, due probably to the presence of dissolved carbides. Below 650° C. the phosphorus diffuses very slowly in ferrite, but above this temperature the velocity increases, being quite rapid above 850° C. The phosphorus diffuses in γ -iron in a similar manner, but not so fast as the carbon. Heating steels slowly through the critical range produces a cellular structure also due to the movement of the phosphorus, the temperature at which this structure

is formed depending on the carbon content. By heating sections of steel to temperatures just below Ac3 the excess of phosphorus contained in micro ghost lines is completely removed, but as the lines still persist, though in a less pronounced manner, their presence appears to be due to the uneven distribution of some other substance besides phosphorus.—T. H. Bu.

Steel ingots; Micro-pipes of —. G. Charpy. Comptes rend., 1920, 170, 306—311.

MICRO-PIPES occurring in steel ingots are most frequently observed in the centre of the ingot, and it is suggested that this is due in part to the meeting of the dendritic crystals coming from opposite walls of the ingots. These micro-pipes may be distinguished from the *retassures en chapelets* (prolongations of the ordinary "pipe") by their sinuous form and their general orientation. They appear to be the origin of local faults which may, in some cases, become serious. Working the metal hot may, under certain conditions, diminish these faults, or, on the contrary, may materially accentuate them. Thus forging or rolling into plates may have a considerable effect on the quality of the products.

—W. G.

Steel; Effect of initial temperature upon physical properties of —. J. H. Andrew, J. E. Rippon, C. P. Miller, and A. Wrang. Iron and Steel Inst., May, 1920. [Advance proof.] 82 pages.

THE volume change which takes place in steel on passing through the transformation points is composed of two changes, working in opposition, the allotropic change and that due to the carbide. The latter is not complete at the ferrite line in steels of high carbon content. Quenching merely stereotypes the condition of the carbide. At and above the normal transformation temperature the carbide dissociates. Nickel-chrome steels behave in a similar manner except that the time factor is of a lower order. Martensite is probably a solution of the dissociated carbide in α -iron, and in those cases where the austenite to pearlite change occurs at the normal Ar1 point martensite is not an intermediate product. The hardening which takes place when an austenitic steel is tempered is ascribed to the association of the carbide with the resulting occurrence of the allotropic change. Electrolytic separation of the carbide in nickel-chrome steel in which the transformation has not taken place at the normal temperature shows a complete absence of chromium, and the abnormalities of nickel-chromium steels are probably due to iron carbide which has been rendered more stable by the special elements present in solution. When quenched from 1000° C. the iron in plain carbon steels is entirely in the α -state; in alloy steels γ -iron is present in varying proportions, particularly when the carbon content is high, while in extreme cases α -iron is absent. A novel form of dilatometer used in the work at high temperatures is described.—F. C. Th.

Steels; Embrittling effects of cleaning and pickling upon carbon —. S. C. Langdon and M. A. Grossman. Trans. Amer. Electrochem. Soc., 1920, 305—338. [Advance copy.]

REMOVAL of grease by organic solvents or alkali, even when the steel was electrolytically cleaned (as cathode) in a solution of alkali, did not affect the strength of the steel, but vigorous pumice brushing caused a reduction in strength due to the scratching of the surface. Sand-blasting caused appreciable reduction in the ability of rods in the "raw" state and after being "normalised" to withstand the alternating stress test, particularly with steels of low carbon content. Steel with 0.98% C when hardened and tempered was, however, improved by sand-blasting. Cold-rolled strip was only slightly reduced in ductility. The effect of sand-blasting is probably one of hardening due

to cold work. Pickling for 5 min. in 2N sulphuric acid at 50° C., or in nitre-sulphuric solution, hydrochloric acid, or hydrofluoric acid, of equivalent acid concentration, produced in all cases similar embrittling effects. With rods, stock as received was rendered increasingly brittle with increasing carbon content up to about 0.54% C. In high carbon steel the effect was less marked. The brittleness produced in normalised rods decreased, but in hardened and tempered rods increased with increasing carbon content. The effects were almost independent of size from $\frac{1}{8}$ in. to $\frac{1}{2}$ in. in diam. With cold-rolled strip steel the brittleness produced was greater in proportion to the amount of "work" which the specimen had received, and increased with the thickness of the strips. In general, increasing the temperature of the pickling bath from 0° C. to 50° C. caused increased brittleness, but above 50° C. increasing the temperature had little effect. Brittleness increased with the time of immersion markedly up to 5 min., after which the increase was more gradual. Nitric acid produced practically no brittleness. Electrolytic pickling caused about the same degree of brittleness as was produced by simple immersion in the same acid for the same period. Electrolytic "pickling" as anode or cathode in a neutral solution of sodium sulphate produced no brittleness, although hydrogen was evolved vigorously upon the cathode surface. Specimens which had been rendered brittle by pickling became less brittle on standing, slowly at the ordinary temperature and more rapidly at higher temperatures. It is concluded that pickling produces a permanent effect, caused by the roughening of the surface, and a temporary effect, due probably to occlusion of hydrogen.—T. St.

Chromium steels; Structure of —. J. H. G. Monypenny. Iron and Steel Inst., May, 1920. [Advance proof.] 26 pages.

In the case of many of these steels it is the carbide of the cementite which first goes into solution at the change point on heating, the pearlite carbide passing into solution at a higher temperature, which increases as the chromium and carbon contents of the steel are raised. The carbon contents at the eutectoid points are much lower for the chromium steels than for plain carbon steel, the following figures illustrating the influence: 2% Cr, 0.66% C; 6% Cr, 0.5% C; 10% Cr, 0.35% C; 15% Cr, 0.2% C. In the case of a steel with 1.1% C and 2.8% Cr, in the quenched condition, when etched with sodium picrate two distinct carbides are to be seen; one of these, presumably cementite, is darkened, while the other is comparatively unattacked. Austenite in these steels is transformed into martensite by cold-work and by tempering, but attempts to obtain martensite directly by slower cooling were only partly successful, mixtures of martensite and troostite always being obtained. Steels quenched from 1200° C. are austenitic if they lie to the right of a straight line running from 0.6% C and 15% Cr to 1.05% C and 5% Cr and completely martensitic if to the left of a parallel line from 0.45% C and 15% Cr to 0.8% C and 5% Cr. Between these two lines the structure is austenite-martensite. A steel rendered austenitic by quenching, if it lies near the limiting line, is spontaneously transformed in part into martensite. In the austenitic steels the effect of tempering is comparatively small up to 500° C. when a sudden and considerable increase of hardness sets in. There do not appear to be any distinct areas in the diagram in which different double carbides exist (cf. Murakami, J., 1919, 257 A). The effect of increasing chromium content is progressive. The rate of diffusion of carbides in chromium steel is much slower than in plain carbon steel, with the result that much longer time is required at a given temperature to produce equilibrium.—F. C. Th.

Iron-chromium-carbon steels; Properties of —. 1. *Thermal analysis.* C. A. Edwards, H. Sutton, and G. Oishi. Iron and Steel Inst., May, 1920. [Advance proof.] 44 pages.

In presence of chromium the carbon change point on cooling is raised considerably to an extent depending on both the chromium and the carbon contents of the steel. With a constant carbon or chromium content the highest A₁ point is reached when the ratio of the chromium to the carbon is about 10:1. The annealed steels contain a definite double carbide, Fe₃C.Cr₃C₂. It is concluded that a carbide Cr₃C does not exist, but in the high chromium steels in the annealed state the carbide Cr₃C₂ is probably present. The steels can be divided into two groups—first, those with Cr/C less than 10, which possess similar hardening properties to ordinary steels; and, secondly, those with a higher ratio of chromium to carbon which have lower critical cooling velocities and which can therefore be air-hardened. The boundary line is not sharply defined and depends on the content of silicon and manganese in the steel. Possibly the air-hardening properties of these steels may be due to the dissociation of Cr₃C₂ into Cr₃C₂ and free chromium.

—F. C. Th.

Chromium steels. II. Effect of heat treatment on electrical resistivity. C. A. Edwards and A. L. Norbury. Iron and Steel Inst., May, 1920. [Advance proof.] 36 pages.

In the annealed condition the addition of chromium to steel has little or no influence on the electrical resistance until the amount is increased above 4.3 times the carbon content. It is concluded that within this range of composition virtually all the chromium is in combination with the carbon, the carbide existing as isolated patches in a chrome-free ferrite. With higher contents of chromium the resistance is increased by 3.75 microhms for each 1% Cr. The change occurs at a composition corresponding to the formula Fe₃C.Cr₃C₂, and this double carbide is probably present in these alloys. Excess of chromium above that required to form this carbide is present partly in solid solution in the ferrite and partly as a new carbide, probably Cr₃C₂. Quenching experiments show that there is a second critical range of temperature for these steels at about 1000° C., and the maximum resistance is not attained until this has been exceeded. During tempering the loss of resistance takes place in two stages around 200° C. and 500° C. respectively. At the lower temperature the carbide which falls out of solution may be the ordinary iron carbide, whereas that which is deposited at the higher temperature may be either Cr₃C₂ or Cr₃C₂. So far as the chromium in solid solution is concerned, an increase of 1% raises the resistivity by 5.1 microhms per cm. cube.—F. C. Th.

Nickel-chrome and other steels; Brittleness in —. F. Rogers. Iron and Steel Inst., May, 1920. [Advance proof.] 5 pages.

The paper contains the data on which the earlier conclusions were based (J., 1919, 774 A).—F. C. Th.

High-speed steel containing chromium and tungsten; Constitution, hardening, and tempering of —. K. Honda and T. Murakami. Iron and Steel Inst., May, 1920. [Advance proof.] 11 pages.

In the annealed state a high-speed steel containing about 5% Cr and 18% W with 0.6% C consists of iron with tungstide in solution, free tungstide and the carbides Cr₃C and WC in the free state. If the steel be heated above the A₁ point the carbides dissolve in the austenite and undergo the following changes: 2Cr₃C=Cr₃C₂+5Cr and 2WC+3Cr+4Fe=2Fe₃W+Cr₃C₂. The higher the temperature the

greater the extent to which these changes proceed from left to right, but on normal cooling from the high temperature the reverse change takes place but slightly, with the result that the carbides and tungstide remain in solid solution. The separation of the carbides on tempering produces an increase in the magnetisation, whence this property affords a ready means of studying the changes in the solution. The tempering takes place in two stages at about 400° C. and 700° C. The self-hardening and the resistance to tempering depend principally upon the quantity of Cr_3C_2 in solution, and hence these properties increase with the carbon and chromium jointly. The maximum temperature attained, since it determines the extent to which the changes have occurred, also has an influence. Tungsten in high-speed steels diminishes the temperature at which hardening begins on cooling. Above 12% tungsten exists as fine globules of Fe_3W , and these, acting as saw teeth, increase the cutting efficiency rather than the hardness of the steel. The globules of tungstide are darkened by etching for 10 to 15 secs. in a cold alkaline solution of potassium ferricyanide. As cast the tungstide is found as a eutectic, but in the tool the globules must be uniformly distributed.—F. C. Th.

Assaying; Volatilisation losses in —. F. P. Dewey. Amer. Inst. Min. Eng., Feb., 1920. Chem. and Met. Eng., 1920, 22, 797—802.

Losses of gold, silver, and lead in assaying are not ascribable to volatilisation except in rare cases due to excessive temperature. They are largely due to dusting and other mechanical causes, the working up of very fine slimes tending to promote loss of this kind. Only minute quantities of precious metals are traceable in the fumes condensed in muffle flues. The drag exerted by one metal on a less volatile one, in cases where true volatilisation takes place, is slight.—W. J. W.

Micrometallurgy. [Copper-silicon and iron-silicon alloys.] S. Bogdan. Bul. Soc. Chim. Rom., 1919, 1, 60—72.

A MICROGRAPHIC study of copper-silicon and iron-silicon alloys showed that when the silicon content is very small the product is a homogeneous solid solution, but when the silicon content exceeds 1% crystalline compounds, probably silicides, are always obtained embedded in the solid solution. When the percentage of silicon present exceeds 4 two crystalline silicides can be isolated as well as silicon itself in both the crystalline and the amorphous state. Prolonged heating of the alloys at high temperatures facilitates the separation of their components. As the proportion of silicon present increases still further, the mass becomes more crystalline, the hardness increases, and the alloy becomes more brittle.—W. G.

Duralumin; Heat treatment of —. P. D. Merica, R. G. Waltenberg, and H. Scott. U.S. Bureau of Standards, Sci. Paper 347. Nov. 15, 1919. 41 pages.

WHEN duralumin (Cu 0—4.5%, Mg 3.5—0%, commercial Al the remainder) is quenched from between 250° and 500° C., and then aged between 0° and 200° C. the hardness and, especially at the lower ageing temperatures, the ductility increase; the actual value of these properties also increases with the temperature of quenching up to 520° C. This increase corresponds to the increase of CuAl_2 in solid solution in the aluminium. At 520° C. this compound melts as a eutectic, and the metal is spoilt. In order to obtain the best mechanical properties the alloy should be quenched from temperatures as near this as possible. By heating for 10—20 mins. at 510°—515° C., quenching in boiling water, and allowing to age at 100° C. for 5—6 days, maximum values for tensile strength and ductility

are obtained. To develop a higher proportional limit the alloy should be aged at 150° C. for 2—4 days. The composition of the most satisfactory alloy is Cu 3—4.5%, Mg 0.4—1%, Mn 0—0.7%, Al (99%) remainder. The alloy should be preheated to 500° C. before rolling and rolled at 450° C. It is suggested that the hardening observed on ageing is due to gradual precipitation of the compound CuAl_2 from solid solution in a colloidal form dispersed throughout the mass.—A. R. P.

Alloys of aluminium and magnesium with copper, with nickel, and with manganese; Mechanical properties and resistance to corrosion of rolled light —. P. D. Merica, R. G. Waltenberg, and A. N. Finn. U.S. Bureau of Standards. Tech. Paper 132, 1919. Pp. 13.

ALLOYS of the three series Al-Mg-Ni, Al-Mg-Mn, and Al-Mg-Cu were prepared with varying amounts, up to a total combined content of 4.5%, of the hardening metals, and cast into slabs 3.5 in. thick. These were then rolled down to 0.032 in. thick, the final rolling being in the cold, after annealing at 400°—450° C. Hardness and tensile tests were made on the sheets in the cold-rolled condition, after annealing at 422° C., and after heat treatment consisting of quenching from about 500° C. and allowing to stand or "age" for several days either at 110° C. or at room temperature. The Al-Mg-Cu alloys gave better tensile results in all conditions than those of the other series, and showed improvement under appropriate heat treatment, as compared with the annealed specimens. The Al-Mg-Ni alloys also were improved by heat treatment, but not to the same extent as the Al-Mg-Cu alloys. The Al-Mg-Mn specimens were not improved by heat treatment. In the annealed condition, and for equal additions, either with or without magnesium, copper had the greatest hardening effect, and manganese was more effective than nickel. The Al-Mg-Mn alloys in general resisted corrosion by salt water best, the heat-treated Al-Mg-Cu alloys being but little inferior. The latter alloys, in the cold-rolled and annealed states, were, however, the least resistant to corrosion of any of the alloys tested. Hard-rolled commercial aluminium corroded much more than any of the alloys. Annealed aluminium was more resistant than the hard-rolled metal, but did not compare favourably with most of the alloys.—T. St.

Zinc muffles; Colouring matter formed in old fragments of — and the changes due to muffle and furnace gases. O. Mühlhaeuser. Z. angew. Chem., 1919, 32, 53—56.

IN spite of the enveloping silicious skin, gases penetrate the walls of zinc muffles through pores and cracks. The various colours observed in the retort material and glaze are associated with the changing character of the gases and with the materials contained in the binding clay. The various colours observed and their causes are described.—T. H. Bu.

Lead; Hardening effects of various elements upon —. C. O. Thieme. J. Ind. Eng. Chem., 1920, 12, 446—448.

AN alloy of lead with about 1% of calcium has a Brinell hardness of about 15, but appears to lose its hardness when re-melted several times owing to oxidation of the calcium. Addition of sodium to lead increases the Brinell hardness up to about 8 at 0.8% Na (the maximum dissolved by the lead); the alloy loses its hardness after re-melting several times. Arsenic (0.5 to 1%) hardens and increases the fusibility of lead. An alloy of lead with 2% Ni is resonant. Alloys of lead with antimony in amounts exceeding 18—20% are too brittle for practical use. Up to the eutectic point (13% Sb) the hardness increases approximately one Brinell number for each 1% Sb. An alloy of 90% Pb and

10% Sb has a hardness of about 14, and an alloy containing 18% Sb a hardness of about 16. By adding 1% phosphor-copper to this alloy the hardness is increased to about 24, but the product is more brittle, loses its lustre more rapidly than the lead-antimony alloy, and is difficult to cast, since it readily segregates. Magnesium also hardens the alloy of lead and antimony, 0.5% increasing the hardness to 17.5. This alloy soon loses its lustre. The addition of 5% tin to the lead-antimony alloy increases the hardness to about 19, and a further addition (up to 8%) gives a fine-grained alloy with hardness of about 20. It retains its lustre fairly well and takes a good polish. Each increase of 1% Sn increases the hardness by about 1 Brinell number, but such alloys should not contain more than about 10% Sn unless the antimony is correspondingly increased. An alloy of lead with about 0.5% Mg has a hardness of 15; it does not oxidise rapidly, and therefore retains its lustre and hardness on re-melting. The addition of mercury (up to 7%) increases the hardness of lead.—C. A. M.

Tungsten; Estimation of —. R. F. Heath. Chem. Trade J., 1920, 66, 629.

The finely powdered ore (0.5 g. if low grade or 0.2 g. if a concentrate) is fused with 5 g. of sodium peroxide in a nickel crucible. In the analysis of steels and mattes the sample is first dissolved in hydrochloric and sulphuric acids, the solution evaporated to dryness, and the residue fused with peroxide. In either case the melt is leached, the insoluble matter filtered off, the filtrate diluted, and an aliquot part treated with 6–7 c.c. of the test solution (10.3 g. of stannous chloride and 2.1 g. of stannic chloride dissolved in 100 c.c. of dilute acetic and 40 c.c. of syrupy phosphoric acid) and 3–4 c.c. of strong sulphuric acid; after standing 3–4 mins. the blue colour produced is compared with that of a standard solution of tungsten treated in the same way.

—A. R. P.

Tungsten; Analysis of —. J. Erlich. Ann. Chim. Analyt., 1920, 2, 102–103.

Two grms. of the sample is heated for 2 hrs. with 100 c.c. of hydrochloric acid and 30 c.c. of 30% ferric chloride solution; the insoluble portion is washed with ammonium nitrate solution, ignited, and weighed. The ignited residue is fused with sodium bisulphate, the melt dissolved in ammonia, the solution oxidised with bromine, treated with ammonium carbonate, and the precipitate (impurities) collected and weighed. The difference between this and the first weight gives the amount of tungstic oxide present. It may be found necessary to repeat the fusion with sodium bisulphate in order to separate all impurities from the tungstic oxide.

—W. P. S.

Amalgams; Electro-endosmosis and the preparation of solid alkali —. S. B. Frank and J. R. Withrow. J. Amer. Chem. Soc., 1920, 42, 671–675.

Solids amalgams of potassium and strontium are obtained by electrolysis saturated solutions of potassium chloride or sulphate or strontium chloride respectively between a platinum anode and a mercury cathode. A porous cell 40×80 mm. containing about 50 g. of mercury is suspended so that it dips about 5–10 mm. into the saturated solution, contacts are made in the usual way, and the current passed for about 1 hr., using a voltage of 25. (Cf. J.C.S., ii., 350.)—J. F. S.

Sodium amalgam; Preparation of — in flakes. A. D. Hirschfelder and M. C. Hart. J. Ind. Eng. Chem., 1920, 12, 499.

Hot liquid sodium amalgam is slowly poured into a jar containing xylene or kerosene which is being rapidly stirred by an electric stirrer. The fine flocculent deposit is dried on a porcelain plate in a current of air, and may then be readily pulverised.

—C. A. M.

[Hardness of metals.] “Ball test.” T. Baker and T. F. Russell. Iron and Steel Inst., May, 1920. [Advance proof.] 16 pages

If L is the load in the Brinell test, V the volume of the indentation, and d the diameter of the impression, then $L = bV^m$ and $L = ad^n$ where a , b , n , and m are constants. It is shown that n is a measure of the cold-work put upon the material, and in the completely work-hardened state is equal to 2. As this condition is approached the curves expressing the relation of the Brinell number to the load used in the test becomes more and more horizontal. By plotting in the stress-strain curve the stress against the contraction of area divided by the reduced area a curve is obtained which is free from the arbitrary character of the ordinary test. When this is done there is no point of inflexion in the upper part of the curve comparable with that usually shown. Where it is not possible to use the 10 mm. ball, the following procedure may be adopted. If the ratio of the load to the square of the diameter of the ball is kept constant, $D, d/d$, is the diameter of impression under standard conditions where D is the diameter using a ball of diameter d , and d is the normal 10 mm.—F. Steel; Manufacture of —. G. A. Jarvis. E.P. 141,956, 4.6.19.

The main portion of scrap is preheated to about 800° C. and then introduced into a furnace containing a smaller portion of scrap, having an excess of carburising material to give the desired carbon content to the full charge.—T. H. Bu.

Steel scrap; Method of utilising —. G. M. Muntz and E. M. Roubieu, Assrs. to Tropenas Co. U.S.P. 1,336,236, 6.4.20. Appl., 25.6.17.

In melting steel scrap in a cupola, a melt is first produced with metal of lower fusing point than the steel scrap, and then successive charges comprising steel scrap largely in excess of metal of lower melting point are melted, the sizes of the charges being so proportioned that there is a practically continuous rain of molten metal at high temperature to the hearth of the cupola.

Mercury; Process for decomposing — and obtaining radium and gold. G. B. Perez. E.P. 126,961, 12.5.19. Conv., 15.5.18.

MERCURY is introduced into a central depression in a vacuum tube similar to a Crookes tube and subjected to the electric discharge from an induction coil between two pointed electrodes arranged a short distance above the mercury and inclined downwards towards its surface. The mercury is said to be decomposed into metallic gold and a radio-active substance.—T. H. Bu.

Iron; Bessemerising —. R. S. McCaffery. U.S.P. 1,338,655, 27.4.20. Appl., 13.11.18.

MOLTEN iron, without basic additions, is bessemerised in a converter having an acid lining except

at the part where basic products may be formed during the process.—W. E. F. P.

Iron; Production of — in an electric furnace. G. J. Stock. U.S.P. 1,338,881, 4.5.20. Appl., 13.2.20.

ORE is fed steadily to the furnace at a rate sufficient to balance the electrical energy consumed in melting the charge and raising it to the required temperature, whereby the latter is maintained substantially constant.—T. St.

Iron resistant to cutting; Process for the production of —. Deutsch-Luxemburgische Bergwerks- und Hütten A.-G., and H. Lütke. G.P. 317,671, 6.6.18.

IRON containing phosphorus (Thomas iron, old cast iron etc.) is smelted with scrap in a basic furnace under a layer of slag, the phosphorus content of which has been increased to such an extent that it can absorb no more from the melt. In the preparation of the melt the phosphorus content can be regulated by the addition of more slag on the one hand, or of lime on the other. Since the molten metal is covered during the whole process with a layer of slag, no injurious gases can be absorbed from the flue gases; and further, since the smelting process is carried so far that the phosphatic slag is in equilibrium with, and therefore non-reactive towards, the iron, a product is obtained particularly free from gas and suitable for casting. The metal is especially resistant to cutting and suitable for nuts etc.—G. F. M.

Iron and steel; Determination of the content of non-ferrous constituents, especially carbon, in —. B. D. Enlund. G.P. 319,255, 22.11.18.

A MEASURE of the total non-ferrous elements in iron and steel is given by the electrical resistance of the fully hardened specimen, and of the carbon content by the difference in electrical resistance of the specimen in the hardened and unhardened states. The increase in resistance with hardening is greater when the iron contains only small amounts of silicon and manganese, and standards with varying amounts of these elements are therefore necessary when the carbon content is high.

—T. St.

Nickel salt; Method and apparatus for electrolysing a solution of a —. C. Heberlein. E.P. 141,766, 29.10.18.

NICKEL is dissolved from ore, matte, or the like, by means of an acid until a liquor of not more than 2% acidity is obtained, which is circulated as catholyte through a number of electrolytic vats in series. As an anolyte nickel salt solution is used. When the acidity of the anolyte is sufficient for dissolving nickel from fresh ore, matte, etc., it is withdrawn to be used for preparing fresh nickel salt solution. The catholyte is returned into circulation with fresh nickel salt solution, the acidity being not more than 2%. The process is thus continuous and cyclic. Insoluble stationary anodes and stationary cathodes are used.—T. H. Bu.

Nickel; Process for recovering — from cupro-nickel alloys, scrap, and the like. A. McKechnie, and McKechnie Bros., Ltd. E.P. 142,310, 10.5.19.

THE charge of alloy or material containing metallic copper or nickel is rapidly melted on the hearth of a basic reverberatory furnace and maintained under heat while air is blown through; or the molten charge may be bessemerised in a basic converter. The treatment by either method is continued until the whole or part of the nickel content is volatilised. The nickel is recovered from the furnace fume in the form of nickel oxide.—J. W. D.

Nickel; Preparation of finely divided — for catalytic purposes by reduction. H. Schlink and Co. G.P. 318,177, 5.8.16.

THE material to be reduced is passed downwards in the form of powder over a number of electrically heated plates arranged in tiers, whilst the reducing gas, for example hydrogen, is led in from below.

—E. H. R.

Lead; Dezincing of —. H. Harris. E.P. 142,315, 16.5.19.

MOLTEN lead is brought into intimate contact with a molten mixture of either an alkali chloride and caustic alkali, or an alkali chloride and zinc chloride in presence of oxygen.—J. W. D.

Lead; Refining of —. H. Harris. E.P. 142,398, 16.5.19.

MOLTEN lead partially oxidised by means of an air spray is charged into a distributor from which it issues in the form of thin streams and is passed through a suitable molten reagent (e.g., common salt) until the impurities most easily removed by the reagent (e.g., copper) disappear from the lead. The molten metal is then passed through a fresh molten reagent to remove other impurities (e.g., arsenic, tin, and antimony).—J. W. D.

Metallurgical method and apparatus. Production of lead. G. F. Greenwood. U.S.P. 1,338,439 and 1,338,440, 27.4.20. Appl., 19.7. and 23.7.18.

LEAD sulphide ores are roasted in an electric furnace so constructed that the sulphur dioxide is withdrawn by suction and air is drawn through the charge. The roasted ore is transferred to an electric reducing furnace and reduced by carbon and heat with exclusion of air, at a temperature and pressure less than atmospheric, favouring the production of carbon monoxide. The carbon monoxide is removed and burned to carbon dioxide in a gas engine, which is used to generate an electric current for heating in the reducing reaction.

—J. W. D.

Alloy; Electric-resistance —. W. A. Scheuch, Assr. to Western Electric Co. U.S.P. 1,337,276, 20.4.20. Appl., 3.8.17.

THE alloy contains more than 50% Ni, $1\frac{1}{2}\%$ or more Co, and titanium.—T. H. Bu.

[Alloy.] *Composition of matter and process of making same.* H. B. Blumenberg, jun., Assr. to F. Blumenberg. U.S.P. 1,338,279, 27.4.20. Appl., 23.2.17.

A METAL and a compound of an element of the nitrogen group, bismuth and nitrogen excepted, capable of generating a volatile hydride on contact with water, are fused together by means of an electric current of low voltage.—J. W. D.

Alloy. F. Milliken, Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S.P. (A) 1,338,517 and (B) 1,338,518, 27.4.20. Appl., 11.12.18.

THE alloys contain 50–60% Cu, 26–34% Ni, 4–8% Fe, 7–11% Zn, the metals being in a deoxidised state, and in addition (A) contains tungsten and (B) chromium.—T. H. Bu.

Alloy. G. L. Van Allen, Assr. to Baker and Co., Inc. U.S.P. 1,339,009, 4.5.20. Appl., 21.9.18.

THE alloy contains Au 64%, Ag 18.75%, Cu 9%, Pd 8%, and Al 0.25%.—B. M. V.

Metals; Process of melting and melting and reducing —. M. H. Bennett, Assr. to Scovill Manufacturing Co. U.S.P. 1,337,305, 20.4.20. Appl., 9.2.20.

NON-FERROUS metals of high thermal conductivity are melted in an electric furnace having a closed furnace chamber. An electric current of high

amperage is delivered to the charge through a number of electrodes in such manner that a magnetic field is set up in the melting metal which is thereby caused to circulate. The distribution and adjustment of the current are designed to promote uniform heating, undue volatilisation of the metal around the electrodes being prevented by the circulation of the charge. Any metal volatilised is condensed and returned to the melting chamber.

—W. E. F. P.

Metallic-arc welding. J. Churchward, Assr. to Wilson Welder and Metals Co. U.S.P. 1,337,543, 20.4.20. Appl., 14.1.20.

An electrode for electric arc welding consists of a homogeneous austenitic steel containing more than 12% Mn.—T. St.

Furnace; Metallurgical —. S. M. Howell. U.S.P. 1,337,703, 20.4.20. Appl., 1.7.19.

A combustible mixture of gas or hydrocarbon vapour and air is passed first through a mixing chamber containing metallic chips, then through a perforated plate of refractory material which retains the chips in place, into the furnace chamber.

—B. M. V.

Melting-furnace; Electrically heated —. L. C. Harvey. U.S.P. 1,337,839, 20.4.20. Appl., 11.11.19.

The melting chamber is substantially cylindrical in shape, and has an open upper end and a closed curved bottom. A heating element extends into the open end. The chamber is supported in an inclined position, and means are provided for rotating it about the longitudinal axis.—T. St.

Open-hearth furnace. J. C. Cromwell and W. M. Mehlhorn. U.S.P. 1,338,288, 27.4.20. Appl., 26.6.17.

THREE regenerator units are situated at each end of the furnace, the flue connexions and controlling means for the connexions being arranged to permit either one or both of two units to be connected in series with the third unit, or to be connected parallel with each other to the exclusion of the third unit.—J. W. D.

Roasting furnace; Gas-fired —. Donnersmarchhütte Oberschlesische Eisen- und Kohlenwerke A.-G. G.P. 317,039, 17.7.18. Addn. to 310,283 (J., 1919, 641 a; 1920, 69 a).

A NETWORK of horizontal girders is arranged in the zone where the water of constitution is expelled to obviate irregularities in the working of the furnace. By the retention of the sloping plates the dust can again be separated in the upper chambers. To facilitate the passage of the ore a space is provided above the top layer of girders in which a movable stirrer can be operated.—W. J. W.

Metals; Recovery of — from their ores. H. V. Welch, Assr. to International Precipitation Co. U.S.P. 1,338,271, 27.4.20. Appl., 11.8.17.

THE ore is heated with a suitable reagent to produce a fume containing the metal, the gases containing the fume are brought into contact with a liquid capable of dissolving the metal, and the latter is precipitated electrically from the fume. The metal is subsequently separated from the solution and the liquid used to act on a fresh quantity of fume.—J. W. D.

Zinc alloy. H. Goldschmidt and K. Müller, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,338,826, 4.5.20. Appl., 19.4.17.

A ZINC alloy containing from 0.25 to 4.0% Mn and at least 6.9% Cu+Al, the ratio Cu:Al being about 3:1.—W. E. F. P.

Coating metals; Process for — by spraying with finely-divided metal. Method of obtaining adherent deposits by the spraying process. Process for improving the adhesion of metal coatings. Metalliserator G.m.b.H., in liq. G.P. (A) 318,460, 23.3.15, (u) 318,461, 10.4.15, and (c) 318,462, 1.12.15.

(A) The metal to be powdered and sprayed is first given a coating of fat or vaseline containing reducing substances in a colloidal condition, e.g., gelatin, glue, or "oidlag" or "aquadag" (colloidal graphite). (u) The metal to be coated is first given a thin layer of an easily fusible metal, such as tin or Wood's alloy, and the hot coating metal is then sprayed on to this, so that it melts and thus forms a binder. (c) The metal to be coated is heated to such a temperature that it is alloyed with or welded to the spraying metal. For example, vessels to be coated with lead are heated to 320° C., and iron is heated to 250°–300° C. or copper to 500° C. prior to coating with zinc.—A. R. P.

Non-oxidising atmosphere; Method of heating in a — with avoidance of the production of mill scale. F. K. Meiser. G.P. 319,277, 3.1.18.

THE gaseous fuel used consists substantially of nitrogen and carbon monoxide, and is obtained by the removal of carbon dioxide from semi-producer-gas.—T. St.

Reheating furnaces; Construction of walls or partitions, more especially for use in continuous recuperative —. Wellman Smith Owen Engineering Corp., and A. V. Kemp. E.P. 141,981, 18.7.19.

Castings; Manufacture of [sound] —. H. Wade. From A. J. Griffith. E.P. 142,201, 4.2.19.

XII.—FATS; OILS; WAXES.

Coconut oil; Rancidity of Philippine —. G. A. Perkins. Philippine J. Sci., 1919, 15, 463–474.

THIRTY samples of edible coconut oil were kept for two years under varying conditions of light, air, etc. Oxygen was found to be necessary for the development of rancidity, but not of acidity. The action of light increased the hydrolysis of the fat in sealed bottles, but, on the other hand, all samples exposed to the air in darkness became rancid. Enzymes soluble in fat (but not those insoluble) appeared to have a slight effect, especially in increasing the acidity, but sterilisation of the oil had little, if any, beneficial effect. In the second stage of rancidity the free fatty acids were oxidised to an extent depending upon the amount of hydrolysis. This oxidation was accelerated by light and moisture, but light was not an essential factor. An oil with a low initial acidity remained sweet after exposure to air and light for two years.—C. A. M.

Saponification value [of fats]; Butyl alcohol as a medium in the determination of —. A. M. Pardee, R. L. Hasche, and E. E. Reid. J. Ind. Eng. Chem., 1920, 12, 481–482.

THE use of butyl alcohol (cf. J., 1920, 305 A) gives practically the same values as ethyl alcohol in the determination of the saponification values of the more readily saponifiable oils and fats, but in the case of substances which are more difficult to saponify (e.g., beeswax, spermaceti, and wool fat) the results are higher and more trustworthy after saponification for 30 mins. when butyl alcohol is used. Saponification is complete in 5 mins. in the case of cod liver oil when *n*-butyl alcohol is used as the medium.—C. A. M.

Fatty acids from cottonseed foots; Heat balance of a distillation plant for the recovery of —. J. Alsberg. J. Ind. Eng. Chem., 1920, 12, 490–493.

FRESH fatty acid stock was distilled with superheated steam in a coal-fired still, the volume in which was kept constant. Measurements of the temperature at the different points were made at intervals of 5 mins, the amounts of fatty acids and water in successive portions of the distillate weighed, the cooling water weighed, and an allowance made for surface evaporation; the steam was passed over a barometric condenser, and fixed gases were removed by means of a vacuum pump. In calculating the heat lost by radiation from the shell of the condenser the mean specific heat of the fatty acids was taken as 0.46. The heat balance was calculated from the data obtained, and the total heat above 32° F. per lb. of fatty acids distilled in one experiment was found to be 315.3 B.Th.U.; whence heat of vaporisation per lb. of fatty acids at 24.51 in. vacuum = $315.3 - 0.46(433.8 - 32) = 130.5$ B.Th.U. (433.8° F. is the temperature of the fatty acid vapour).—C. A. M.

Fatty acids; Preparation of — for soap from petroleum oil fractions of high molecular weight. L. Ubbelohde and S. Eisenstein. Mitt. deutsch. Forschungsinst. Textilstoffe, 1918 [4]. Chem. Zentr., 1920, 91, II., 22—23.

PARAFFIN w-x or heavy mineral oil or distillate is slowly oxidised when heated with air or oxygen below 200° C., and much more rapidly in presence of a catalyst such as finely-divided manganese dioxide or stearate. Purified paraffin wax heated for 12 hrs. with 1% of manganese stearate in the presence of oxygen and 2% of water yielded a nearly colourless product with saponif. value 200, and unsaponifiable matter 18—20%. It contained butyric, valeric, and probably caprylic acids, but no known solid fatty acids could be identified. It yielded good soaps.—C. A. M.

Catalyst; New — for hydrogenation [of oils]. W. D. Richardson. Chem. and Met. Eng., 1920, 22, 793—796.

FINELY-DIVIDED nickel, prepared mechanically by abrasion, constitutes an active catalyst for the hydrogenation of oils. The nickel in the form of shot is subjected to the action of abrasives such as ground quartz, pumice, carborundum, diatomaceous earth, etc., Abbé tumbling or pebble mills lined with porcelain being suitable for the operation. Adulteration with portions of the lining is innocuous, but a lining of nickel plates would be preferable. A semi-drying oil was first used in the mill, but water is better, as it produces a more finely-divided catalyst, is less liable to contain catalyst poisons, and forms a film of sub-oxide on the nickel which probably increases the activity if kept down to the narrowest limits. The activity curve of the catalyst shows a considerable rise at the commencement of hydrogenation, which lasts for some time before it reaches its peak and declines. Exposure of the nickel before grinding to temperatures as high as 1470° C does not appear to destroy the catalytic activity. Recovery of the nickel is effected by filter-pressing, then burning to remove fat, followed by mixing with a flux and melting in a furnace. The nickel is then recovered in the form of shot.—W. J. W.

Hydrogenation. Rideal. See XX.

PATENTS.

Oils; Process of removing or decreasing objectionable odours from treated —. J. E. Booge, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,337,339, 20.4.20. Appl., 13.6.18.

BLOWN cottonseed oil having an objectionable odour is blown with steam at 105°—130° C. under reduced pressure.—A. de W.

Fats and oils; Extraction of —. H. Bollmann. G.P. 303,846, 28.9.16.

THE raw materials, such as cereal grains, are placed in a number of containers having perforated bottoms arranged in a closed chamber. The containers are moved through the chamber in one direction, and the solvent falls freely through the containers in succession in the opposite direction, so that its fat content gradually increases.

Resin from species of Xanthorrhoea not previously examined. E. H. Rennie, W. T. Cooke, and H. H. Finlayson. Chem. Soc. Trans., 1920, 117, 338—350.

THE Xanthorrhoea resins from Kangaroo Island and W. Australia, in common with other species, contain p-coumaric acid, either free or as an ester, and p-hydroxybenzaldehyde, and by steam distillation from a strongly alkaline solution the following additional substances were obtained:—From a red resin from Kangaroo Island—a fragrant liquid of vanillin-like odour and paeonol (2-hydroxy-4-methoxyacetophenone). From a yellow resin from X. Tateana—hydroxypaeonol in addition to the above two substances. From a red resin from X. Preissii—a fragrant liquid not identified, l-citronellol, paeonol, hydroxypaeonol, and a compound which was possibly methoxydiphenyl ether.—G. F. M.

PATENTS.

Coating substances to protect them or render them non-porous; Producing materials for —. C. A. Cleghorn, and The Gayner Pneumatic Co. E.P. 141,414, 10.1.19.

“TURKISH birdlime” (prepared from the fruits of Cordia myxa and Cordia latifolia) is dried at a temperature not exceeding 180° F. (82° C.) preferably in a vacuum, and then pulverised, conveniently at the same temperature. It can then be spread in a thin coating on canvas or other material to render it fluid-proof or applied as a liquid-tight jointing material; the powder is finally treated with water.—D. F. T.

Ink compound; Solid —. M. Tsutsumi. E.P. 141,631, 11.9.19.

EXTRACT of logwood and galls (60 pts.) is mixed with

sodium salicylate (0.2 pt.), potassium ferrous tartrate (30 pts.), purified gum arabic (7 pts.), and a suitable proportion of "Soluble Blue" or "Fast Blue." The powder may be pressed into cakes.

—D. F. T.

Ferric oxide; Manufacture of pure — F. Hemingway. U.S.P. 1,337,402, 20.4.20. Appl., 28.8.19.

AN intimate mixture of a ferrous salt and a dry alkaline substance is ground continuously so that the iron is largely converted into the ferric condition, and the resulting powder is calcined at the temperature necessary to produce the desired shade of colour.—D. F. T.

[*Pigment*] *colours; Manufacture of* — G. B. Palmer. U.S.P. 1,339,219, 4.5.20. Appl., 14.6.19.

THE "sulphonic acid-derived pulp known as worms" is filtered and then incorporated with a pigment carrier.—A. de W.

Phenolic condensation product and process of manufacturing. L. V. Redman, A. J. Weith, and F. P. Brock, Assrs. to Redman Chemical Products Co. U.S.P. 1,339,134, 4.5.20. Appl., 6.6.18.

A MIXTURE of a filler, a phenolic body, and a methyleneamine body adapted to "react anhydrously" therewith, is mixed with a fusible phenolic condensation product, together with sufficient methyleneamine substance to complete the conversion to a hard resistant product, and then subjected to moulding and heat treatment to produce a hard resistant body.—A. de W.

Surfaces or the like; Process for rendering — capable of being easily wetted. C. H. Boehringer Sohn. G.P. 318,217, 2.10.17.

A CHOLATE is added to a solution to be used for coating or silvering surfaces or to water colours, bronze colours, inks, or the like, to facilitate the wetting of the surface under treatment.—L. A. C.

Lamplack; Plant for manufacturing — E. Viertel, Assr. to The Chemical Foundation Inc. U.S.P. 1,338,268, 27.4.20. Appl., 17.8.15.

SEE G.P. 295,517 of 1914; J., 1917, 296.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Vulcanising natural and artificial caoutchouc and caoutchouc-like substances. L. Gaisman and J. L. Rosenbaum. E.P. 141,412, 10.1.19.

THE colour bases of basic coal tar dyes are capable of accelerating the vulcanisation of rubber with sulphur, and the vulcanised products are, in some cases, coloured throughout their mass.—D. F. T.

Tyre filling compositions. W. G. Wright. E.P. 142,416, 17.12.19.

SOYA bean oil (25½ pts.), cooled to about 32° F. (0° C.), is mixed thoroughly with calcined magnesia (2 pts.) and Venetian red (½ pt.); sulphur chloride (6½ pts.) is then added quickly, the resulting chemical reaction raising the temperature to 300°–400° F. (about 90°–150° C.). After a few minutes the mixture, having attained the necessary consistency and colour, is poured into moulds and cooled uniformly.

—D. F. T.

Rubber; Method and apparatus for treating [drying] — E. A. Wullenweber, Assr. to Morgan and Wright. U.S.P. 1,337,536, 20.4.20. Appl., 5.10.17.

RUBBER is dried by subjecting it to the action of segregated volumes of heated and humidified gas in circulation, which are successively removed when

excessively humid and replaced by freshly-conditioned volumes of gas, so that the rubber remains moist at the surface until it reaches a uniform, nearly dry condition. The process is carried out in a chamber in which gas is circulated intermittently until saturated, when it is exhausted intermittently and fresh gas supplied intermittently. Automatic means are provided for maintaining the supply and exhaustion of gas, and for maintaining the humidity and temperature inside the chamber.

Guttapercha substitute. G.P. 317,145. See V.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning materials; Preparation of lightly chromed hide powder for the analysis of — G. Baldracco and S. Camilla. J. Soc. Leather Trades' Chem., 1920, 4, 88–92.

ORDINARY liming and subsequent deliming of the skins with hydrochloric acid has many disadvantages. The skins are given a preliminary unhairing, washed in running water for 24 hrs., then treated with a weak solution of ammonia, again washed, and sliced with a razor. The product is dried at ordinary temperatures, ground in a special mill to give a non-chromed hide powder, which is chromed with 2 g. of crystallised chromium chloride per 100 g. of powder for 15 mins., and pressed to eliminate water. The powder cake is broken up, dried in a current of air, ground, and used for the modified method of analysis (J., 1920, 123 A).—D. W.

PATENTS.

Leather; Process for rendering — resistant to chlorine. P. Askenasy. G.P. 299,075, 19.11.16.

THE leather is treated with such chlorinated oils, waxes, etc., as contain less than 30% Cl, or a mixture of such products. These are more suitable than compounds containing more chlorine because they are less resinous in character.—D. W.

Chrome leather waste; Process for detanning — E. Immendoerfer. G.P. 305,598, 8.8.17.

THE waste is treated with aldehydes or quinones, and then submitted to successive strong solutions of alkalis and acids. The aldehyde or quinone renders the felt more resistant to the action of the acids or alkalis.—D. W.

Deliming hides; Process for — R. Haberer und Co. G.P. 317,804, 28.9.18.

WASTE liquors obtained in the removal of the bitter principle of lupins, especially by methods in which no caustic alkali or lime is used, are very suitable for deliming hides, as they do not hydrolyse or dissolve the hide substance even when highly concentrated, and the ammonium salts they contain react favourably on the pelt. The waste liquors may be neutralised with alkalis or alkaline salts before use.—D. W.

Waterproof vegetable-tanned leather; Process for manufacturing — W. Rechberg. G.P. 317,965, 22.2.18.

THE tanned leather whilst still wet is treated with a solution of asphalt, petroleum pitch, rosin, or the like in a volatile organic solvent, dried, and then given a fresh treatment with the impregnating medium.—D. W.

Adhesives; Process of preparing flexible — unaffected by hot water. G. Hoffmann. G.P. 316,604, 17.7.17.

HOT solutions of known adhesives in anhydrous organic solvents are mixed with anhydrous acids and softening agents, and the mixtures cooled and

treated with a small amount of a hardening agent. For example, a solution of cellulose in acetone and amyl acetate is treated with oil and acetic acid, and formalin added to the mixture; or, a solution of anhydrous glue or gelatin in acetic acid is treated with glycerin, and subsequently, when cold, with formalin.—C. A. M.

XVI.—SOILS; FERTILISERS.

Soils; Acidity and acidimetry of —. *The Hopkins and Pettit method for determining soil acidity.* H. G. Knight. J. Ind. Eng. Chem., 1920, 12, 340—344.

In the Hopkins and Pettit method the soil is extracted with potassium nitrate solution and the extract titrated, using phenolphthalein as indicator. The author finds that identical results are obtained when the soil is extracted with *N*/1 potassium nitrate, potassium chloride, sodium nitrate, sodium chloride, or calcium chloride solutions. The acidity of the salt extract of an acid soil is independent of the temperature from 25° to 90° C., but the acidity of the first portions of the extract increases with increase in concentration of the salt solution. The difference in absorption of calcium and potassium from solutions of their bases may be accounted for by precipitation effects. There is a marked basic exchange when a neutral salt solution is added to an acid soil, and alumina goes into solution; this, however, does not account for the total acidity of the solution. Exchange of acid radicles does not take place to any appreciable extent. When an acid soil is extracted with potassium acetate solution, acetic acid may be distilled from the extract.—W. P. S.

Kjeldahl method for crop and soil analysis; Boric acid modification of —. F. M. Scales and A. P. Harrison. J. Ind. Eng. Chem., 1920, 12, 350—352.

The use of 4% boric acid solution (Winkler, J., 1913, 485) for absorbing the ammonia distilled in the Kjeldahl method is trustworthy. Bromophenol-blue is a suitable indicator for the subsequent titration.—W. P. S.

Manganese in plant ashes. Wester. See XXIII.

XVIII.—FERMENTATION INDUSTRIES.

Malling; Changes produced in starch and nitrogenous substances during —. F. Tombeur. Bull. Assoc. Anc. Elèves de Louvain, 1920, 20, 72—85.

A HIGH-GRADE Moravian barley was steeped for 72 hrs. with change of steep water every 12 hrs., malted for 6 days, allowed to "felt" for 1 day, and cured for 48 hrs., first at 45°—50° C. and then at 105°—110° C. The change in the 1000-corn weight (dry) showed a malting loss of 14.36%. The loss of starch during steeping and germinating (due to formation of sugars) was high; the loss during curing (due to formation of decomposition products as well as sugars) was comparatively small. The maximum yield of extract (77.4%) was attained after 12 hours on the kilo, diminishing subsequently (to 75.3%), and it is concluded that the amount of diastase formed during germination is directly proportional to the duration of the process. The total nitrogen-content decreased very slightly during malting, but the soluble nitrogen increased greatly to the first stage of curing and decreased thereafter, thus showing that the amount of nitrogenous matter in wort may be lessened by suitably regulating the kiln temperature. Of the total nitrogen the proportion of soluble nitrogen was 19.17% in the barley and 34.18% in the finished malt. The proportion of coagulable soluble nitrogen decreased to less than one-half between the steeping stage and the end of curing, whilst the proportion of non-coagulable nitrogen increased fourfold.—L. E.

Acidity of worts, beers, and other similar liquids; New methods for determining the —. H. W. Windisch and W. Dietrich. Woch. Bran., 1919, 36, 379—381, 387—390. (See J., 1920, 128 A, 293 A.)

THE presence of both primary and secondary phosphate in a solution ensures the latter against either excessive acidity or excessive alkalinity, i.e., it serves as a "buffer" system. Thus in a solution of primary and secondary potassium phosphates the H-ion concentration changes from 0.64×10^{-3} to 0.61×10^{-8} as the ratio of primary to secondary salt is changed from 32:1 to 1:32. The proportions of free acid and of primary and secondary phosphate in mixtures may be determined by the method previously described (*loc. cit.*) by using capillary active organic bases as indicator. Of the bases tried only eucupine (0.1% solution of the dihydrochloride) proved sufficiently sensitive; it is less convenient than the acid indicator since about 5 mins. must be allowed after each addition of alkali in order that the liquid may acquire its "permanent" viscosity; and further, the viscostagonometer outlet is liable to be rendered greasy by the free base and needs to be cleaned frequently with chromic acid. On adding successive portions of standard alkali to a mixture of free acid and primary phosphate in presence of eucupine

dihydrochloride, the surface tension remains practically constant until the free acid is completely neutralised, at which point it falls rapidly to a value which again alters very slowly until tertiary phosphate begins to be formed, when there is a further rapid fall. The liquid must not contain more than about 1 c.c. of $N/10$ primary salt, otherwise the secondary salt formed during titration will lower the surface tension so much as to render the observation of the formation of tertiary salt rather difficult.—L. E.

Hop bitter acids; Analysis of — and their changes during hop boiling. H. Lüers and A. Baumann. Z. ges. Brauw., 1920, 43, 65–67, 73–76, 81–84, 89–82, 97–101.

THE hop bitter acids lower the surface tension very considerably. Surface tension measurements with the dropping pipette (stalagmometer or viscositagonometer) of Traube were made on hop extracts prepared by boiling 1 g. of the hops with 1 l. of 2% Rochelle salt for 1 hr. under a reflux condenser. There is a certain parallelism between the results and those obtained by the determination of the bitter substances of hops by Adler's method (J., 1912, 1003), and the surface tension method is advantageous in following the degree of extraction during hop boiling, since it shows differences during the later stages of extraction which cannot be detected by Adler's method. Surface tension measurements, ultra-microscopic examination, and ultra-filtration experiments show that the α -bitter acid (humulone) is, in aqueous solution, intermediate between a suspensoid and an emulsoid, its degree of dispersion being affected by the presence of electrolytes or of other colloids. Humulone lowers the surface tension of water to a greater degree in presence of acid than in presence of alkali. Since it lowers the surface tension of water strongly, humulone tends to accumulate at the surface of separation between the water and air or other phase. This property is also possessed by proteins and dextrans, and in conjunction with the high internal friction of the dextrans and products of protein-hydrolysis imparts head-retention to beer. During hop boiling the humulone undergoes a chemical change (resinification) corresponding with which there is a rise of surface tension; the change, which is accompanied by increase of bitter flavour, increases with duration of boiling and with the acidity of the solution. This change is less pronounced when the humulone is boiled with wort than when boiled in aqueous solution, whence it seems that the wort protein protects the humulone to some extent. The β -hop bitter acid (lupulone) and the γ -resin also possess the property of lowering surface tension though to a much less degree than humulone.—L. E.

Beer wort; Conditions requisite for head-formation by —. W. Windisch and V. Bermann. Woch. Brau., 1920, 37, 109–111, 121–125, 129–132, 137–139, 145–147, 153–155.

By using membrane filters (cf. Zsigmondy and Bachmann, J., 1918, 453A) differing in fineness of porosity, it is possible to obtain an approximate measure of the degree of fineness which colloidal particles must possess in order to affect the head-formation of wort, etc. If wort which gives a persistent head is filtered through a membrane filter of sufficient fineness, the ultra-filtrate thus obtained gives, on shaking, an abundant but non-persistent head; in this respect the ultra-filtrate resembles a solution of albumoses. If the residue on the filter is washed free from sugars and salts, dried, and treated with water, part of it dissolves (reversible colloids) and part is insoluble (irreversible colloids). If the ultra-filtrate is treated

with the soluble part of the filter residue it regains the power of head-retention. The soluble part of the filter residue consists in part of non-coagulable protein, but chiefly of non-protein substances, and it appears that whilst the non-coagulable proteins are able to produce head, it is the non-protein substances which render the head persistent. These non-protein substances are of a carbohydrate nature. The proteins which produce head have a high capillary activity, whilst the non-proteins which render the head persistent have a low capillary activity. The authors have employed the "iron value" (analogous to the "gold value" of Zsigmondy, J., 1902, 192) for characterising the colloids which are responsible for head-retention. This "iron value" is measured by the concentration of sodium chloride requisite just to produce turbidity or flocculation of a ferric hydroxide sol in the presence of the colloid. Of the non-proteins which cause head-retention, barley gum appears to be the most active, and there appears to be an optimum proportion between the protein head-producer and the non-protein which causes head-retention. By the addition of a capillary active substance (e.g., amyl or octyl alcohol) which lowers the surface tension of wort, the latter loses the power of head-formation when its surface tension is sufficiently reduced, viz., to 38 or 40 dynes per cm.—L. E.

Yeast; Influence of sudden cooling, during or after fermentation, on —, especially in respect of subsidence. H. Will. Z. ges. Brauw., 1920, 43, 49–51, 57–58.

IN a brewery where, inadvertently, the yeast was kept below 0° C. for 34–36 hours, great difficulty was subsequently experienced with regard to subsidence, the beer remaining quite turbid with suspended yeast; the flavour of the beer also was very prejudicially affected. Experiments showed that the subsidence is not affected by low temperature (0° to –19° C.) either during or immediately after fermentation or 3 or 6 weeks after fermentation, and the difficulty encountered at the brewery must have been due to some other cause.—L. E.

Beer; Use of Bac. Delbrücki in the preparation of stable pale —. H. Lüers. Z. ges. Brauw., 1920, 43, 51–53, 58–61.

ACIDIFICATION of the mash and wort by means of *Bac. Delbrücki* (Windisch, J., 1913, 986), in the preparation of pale beer, improves the colour and flavour of the beer, especially where brewing water of high carbonate-content is used. To restrict the protein-content of the beer as far as consistent with head-retention and palate-fulness, it is advisable to acidify the wort rather than the mash. A small proportion of wort of about 14° Bllg. is treated at 50° C. with a pure culture of the organism, an acidity equivalent to 1.5–1.6% of lactic acid being obtained in 12 hrs. Sufficient of this acidified wort is added to the main mash to neutralise the carbonate of the water, and water softened by boiling is used for sparging. The bulk of the acidified wort is added gradually to the main wort during the whole drainage process, the amount so added (8 hl. per brew of 180 hl. of 12° wort) being such that the wort, after coagulation of the protein, has an acidity, $p_H=5.2$, at which maximum protein coagulation is obtained. The finished beer has a slightly higher acidity ($p_H=4.0-4.2$) than beer prepared in the ordinary way ($p_H=4.3-4.4$) and is characterised by brilliance, good head-retention, and flavour. It also possesses very high mechanical as well as biological stability, being unaffected by strong mechanical agitation. The loss of extract involved in acidification renders the process too costly for ordinary use.—L. E.

Saccharin and dulcin in beer; Detection of —.

A. Baumann. *Z. ges. Brauw.*, 1920, 43, 137—139.

For the detection of saccharin and dulcin in beer the method proposed by Tortelli and Piazza (J., 1910, 1327) gives satisfactory results, but the saccharin isolated is liable to be contaminated with impurities which prevent its crystallisation; this difficulty is avoided as follows:—The residue of saccharin (from 1 l. of beer) left on distilling the ether-petroleum spirit solution (*loc. cit.*) is dissolved in alcohol and treated with a few drops of potassium hydroxide solution and then with a few c.c. of sodium chloride solution and two or three times this quantity of water, shaken with petroleum spirit, and the solution is distilled until free from alcohol, cooled, acidified with 3—4 c.c. of 10% sulphuric acid and again extracted 3 or 4 times with the mixture of ether and petroleum spirit. This extract is washed with a little water to remove acid and filtered; on evaporating the filtrate *in vacuo* at the ordinary temperature the saccharin is obtained crystalline and almost white. The authors have isolated saccharin and dulcin from beer to which 90 mg. saccharin and 10 mg. dulcin or 10 mg. of saccharin and 90 mg. dulcin had been added per litre.—L. E.

Wines; Treatment of the blue "casse" of —. A. Piedallu, P. Malvezin, and L. Grandchamp. *Comptes rend.*, 1920, 170, 1129—1131.

OXYGEN in an extremely finely divided condition, obtained, for instance, by forcing it through a porcelain filter candle under pressure, when passed through wine damaged by blue "casse" is capable of rapidly oxidising the ferrous salts present in such wine to ferric salts. By this means the iron may be eliminated, being precipitated in its ferric state by the tannins present, and such wine after clarification is not liable to further "casse."

—W. G.

Alcohol and water; Vapour composition of mixtures of —. W. K. Lewis. *J. Ind. Eng. Chem.*, 1920, 12, 496—499.

THE results obtained by Wrewsky (*Z. physik. Chem.*, 1912, 81, 1) have been recalculated and extended by extrapolation, and the data expressed graphically in diagrams so as to be applicable to the conditions of industrial distillation. (*Cf. J.C.S.*, July.)—C. A. M.

Fermentation; Sensitiveness of yeast — to the p_H value. H. von Euler and S. Heintze. *Ark. Kemi*, 1917, 7, No. 21, 1—21.

YEAST fermentation of sucrose and dextrose occurs with a maximum velocity in solution of acidity represented by $p_H=5$. In the presence of yeast water or asparagin the maximum velocity is at the same point, but is very much greater than in solutions which contain no nutritive nitrogen compounds. Oxalic acid in solutions up to 0.025N is not a yeast poison nor is chromic acid in dilute solutions. (*Cf. J.C.S.*, July.)—J. F. S.

Saccharase [invertase]; Influence of temperature and acidity on the formation of —. H. von Euler and O. Svanberg. *Ark. Kemi*, 1917, 7, No. 23, 1—32.

THE optimum formation of invertase from yeast occurs at 26°—30° C.; at 35° there is no further formation. At acidity $p_H=2$ the formation of invertase is disturbed, but at $p_H=6-7$ there is a strong formation which amounts to 90% of that under the optimum conditions of acidity.—J. F. S.

Saccharase [invertase]; Temperature sensitiveness of —. H. von Euler and I. Laurin. *Ark. Kemi*, 1917, 7, No. 24, 1—30.

THE activity of invertase is decreased by one half

on heating to 59° C.; at this temperature it has an inactivation constant, $k=5 \times 10^{-3}$. The minimum temperature sensitiveness of invertase lies at an acidity $p_H=4-5$, and this point is the position of optimum enzyme activity. The temperature sensitiveness of separated invertase is a little less than that of the non-separated enzyme due to a protecting action of the cell. Invertase from bottom yeast has a smaller temperature sensitiveness (about 2°) than that from top yeast. (*Cf. J.C.S.*, July.)—J. F. S.

Catalase from Phyllostachys mitis, Riv. Chemical kinetics of catalase I. E. Yamasaki. *Sci. Rep. Tôhoku Imp. Univ.*, 1920, 9, 13—58.

A CATALASE prepared from an edible sprout of a species of bamboo, *Phyllostachys mitis*, Riv., decomposes hydrogen peroxide with a velocity which steadily decreases during the reaction. The enzyme is prepared by crushing the plant with water saturated with toluene and after 24 hrs. pressing and treating the filtrate with absolute alcohol. (*Cf. J.C.S.*, i., 453.)—J. F. S.

Methyl alcohol. Schryver and Wood. See XX.

PATENTS.

Soft drinks [non-intoxicating beverages]; Process of producing —. A. L. Straus. U.S.P. 1,337,027, 13.4.20. Appl., 14.11.19.

BEER that has undergone alcoholic fermentation is boiled to remove alcohol. The residue is mixed with water and treated with an agent to produce a bitter flavour and with a foam-producing material, or it is treated with sufficient citric acid to produce a pungent taste. In either case it is further treated with a carbohydrate sweetening material, salt, and hops. The product is fermented to an alcohol content of less than 0.5%, fined, carbonated, and filtered; it may be carbonated and filtered a second time, if desirable, and is finally carbonated again.—L. E.

Beverages; Process for making non-intoxicating —. W. Wilhelmy, sen. U.S.P. 1,338,803. 4.5.20. Appl., 17.5.19.

A MIXTURE of about 500 lb. of ground, pale malt and about 300 lb. of ground caramel malt is mashed with about 18 brls. of water at 77° F. (25° C.) and boiled for a short time. After settling the wort is drawn off, mixed with about 85 brls. of boiling water, boiled, treated with pre-determined quantities of hops during boiling and sufficient water to make 100 brls. after boiling. The liquor is then drained (from the spent hops etc.), cooled to about 68° F. (20° C.), pitched with yeast (4 lb. per brl.), and allowed to ferment for about 36 hrs. The brew is allowed to cool and stand for a specified period, treated with a body-giving substance, and then carbonated.—L. E.

Yeast; Manufacture of — with little or no production of alcohol. Verein der Spiritus-Fabrikanten in Deutschland. G.P. 304,213, 24.4.15. Addition to 303,222 (J., 1920, 315 A).

THE nutrient solution in which the yeast is pitched contains a mineral salt from which the acid is liberated by the yeast, and this acid combines with the alkali (e.g. ammonia) or alkaline salts present in the inflowing nutrient solution.—J. H. L.

Cellulosic materials; Saccharification of — with simultaneous recovery of citrate-soluble phosphate. Chem. Fabr. Rhénania A.-G., F. L. Schmidt and G. A. Voerkelius. G. P. 316,696, 25.12.17. Addition to 305,120 (J., 1919, 896 A). (See also Ger. Pat. 304,400; J., 1920, 309 A.)

THE hydrolysis of the cellulose ester and the solution of the phosphate are effected by a short boiling in concentrated solution, e.g., with 2—4 parts of

water for one part of wood originally taken. A 10% solution of sugar is thus obtained. Preferably only so much phosphate is used as will yield the amount of free phosphoric acid necessary to saccharify the wood dextrins.—J. H. L.

XIXA.—FOODS.

Milk analysis. G. Ambühl and H. Weiss. Mitt. Lebensmittellunters. Hyg., 1919, 10, 53—75. Chem. Zentr., 1919, 90, IV., 191—192.

Preparation of serum for refractometer measurements.—The reagent is prepared by dissolving 125 g. of mercuric chloride in about 75 c.c. of warm 36% hydrochloric acid and then diluting the solution to 100 c.c. with the same strength acid; 0.3 c.c. of the reagent mixed with 30 c.c. of water should give a refractometer reading of exactly 20°. Milk serum is obtained by mixing 30 c.c. of milk with 0.3 c.c. of the reagent, and filtering the mixture. The quantity of added water in a milk calculated from the refraction of the serum agrees with the amount actually present if this does not exceed 35%; with from 40 to 60% of added water the results are 2.5—4.5% too low. The refractions of serums prepared with mercury chloride are usually 3.0°—3.4° higher than those of serums prepared with calcium chloride, but the difference is less in the case of sour milks.

Detection of nitrates in milk.—The method described by Tillmans and Splittgerber (J., 1912, 249) is trustworthy, but not that of Tillmans (*ibid.*, 1911, 44). The test may be applied to the mercury chloride serum obtained as described above; nitrates are decomposed gradually in milk and about one-half of the quantity may disappear within one month. The reagents themselves and the filter paper used must be tested for nitrates.

—W. P. S.

Butter and margarine; Detection of coal-tar dyes in —. G. Van B. Gilmour. Analyst, 1920, 45, 173.

ABOUT 1 c.c. of the clear filtered fat is heated in a test-tube at 185° C. and shaken occasionally; in the absence of coal-tar dyes the fat will become colourless within 10 mins., but in their presence the fat remains coloured. The fat must be separated previously at a moderately low temperature since butter fat separated (from curd, etc.) at above 100° C. does not become colourless when heated at 185° C.—W. P. S.

Cellulose as cattle fodder; Use of —. F. Scurti and G. Morbelli. Staz. Sper. Agrar. Ital., 1919, 52, 233—265. Chem. Zentr., 1919, 90, IV., 1112—1113.

MAIZE cobs contained 38.6% of crude cellulose, 1.75% of crude proteins, and 46.3% of substances soluble in dilute hydrochloric acid. By digesting the cellulose for 2 hrs. with 10 pts. of 0.125—2.5% sulphuric acid 45.2—53.3% of the cellulose was dissolved, of which 32.96—47.5 consisted of reducing sugars calculated as dextrose. The residue consisted mainly (up to 74%) of cellulose. The best results were obtained when the quantity of acid was 4% of that of the material. Reduction of the amount of liquid or of the acidity, or increase of the pressure to 5 or 10 atm. caused reversal of the hydrolysis. The yield of sugars was also reduced by reducing the period of hydrolysis to 1 hr. or prolonging it beyond 2 hrs. The soluble carbohydrates contained dextrose, arabinose, and xylose.

Preserving organic materials [e.g., foodstuffs]. R. Pape. E.P. 142,169, 24.1.19.

ORGANIC material, e.g., a foodstuff such as milk, is heated at 70° C. or at 98°—100° C., and at the same time is subjected to a gaseous pressure of 2 atm. or more during the whole period of heating. During the heating the material is kept in a state of agitation to increase the amount of gas dissolved and to prevent superheating. In order to maintain the original taste, smell, and colour of the material the heating may be conducted at 40°—60° C. and the gases introduced heated to 250°—350° C., or, conversely, the material may be at a high temperature—say 120° C.—and the gases introduced at a low temperature—say 20° C.—J. H. J.

Eggs; Method of preserving —. H. J. N. H. Kessener and N. L. Söhngen. G.P. 312,505, 17.3.17.

Eggs are coated with a solution of cellulose acetate in ethyl acetate; the coating does not affect the taste or vitality of the eggs.—W. P. S.

Beverage extract; Solid soluble — and process of manufacturing same. J. K. Lippen, Assr. to Postum Cereal Co. U.S.P. 1,338,231, 27.4.20. Appl., 1.4.18.

SORGHUM grains are flaked and the flour is separated, dextrinised, and re-mixed with the flakes. Dextrinised wheat and barley flours, rye middlings, and molasses are added, and the mixture is roasted at a caramelising temperature. The product is extracted with water, and the solution evaporated to dryness.—J. H. J.

Fruit-juices; Process of treating —. F. L. Dunlap and R. A. Kuever. U.S. Pat. 1,338,684, 4.5.20. Appl., 24.9.18.

A PROTEOLYTIC enzyme active in slightly acid media is added to citrus fruit juice, which is then heated sufficiently long to enable the enzyme to digest the proteins of the juice.—J. H. J.

Drying fruits, vegetables, and other substances; Method of and apparatus for —. G. H. Benjamin. U.S.P. 1,339,092, 4.5.20. Appl., 16.4.17.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Alkaloids; Rapp's method for determination of —. A. Heiduschka and L. Wolf. Süddtsch. Apoth.-Zeit., 1920, 60, 142–143. Chem. Zentr., 1920, 91, 11., 581–582.

Low results by Rapp's method for estimation of alkaloids (J., 1919, 336 A) caused by partial absorption of the chloroform by the plaster of Paris paste, may be prevented by mixing sand or powdered glass with the paste. For the assay of cinchona bark, 3 g. is heated with 15 c.c. N/2 hydrochloric acid on the water bath for 10 mins., cooled, agitated for 5 mins. with 60 c.c. of chloroform and 3 c.c. of 20% sodium hydroxide, and then for 1 min. with 30–35 g. of plaster of Paris. The chloroform, after separation, is filtered and 50 c.c. is shaken for 1 min. with 12.5 c.c. of N/10 hydrochloric acid,

diluted with 12.5 c.c. of water, and 20 c.c. of the mixture finally titrated with N/10 potassium hydroxide; the percentage of quinine is given by $(10 - \text{c.c. } N/10 \text{ KOH})300 \div 2$. In the case of *Semen strychni* it is sometimes difficult to obtain a clear chloroform solution, even after repeated extractions with benzene. 100 g. of the alkaloid solution in ether-chloroform is evaporated to small bulk, treated with 25 c.c. of chloroform, and shaken with 20 c.c. of 2% sulphuric acid. After clarification, the solution is passed through a filter half filled with moistened plaster of Paris, 14 c.c. of the clear filtrate being mixed with 3 c.c. of 15% sodium hydroxide and shaken for 3 mins. with 70 c.c. of chloroform and 25–30 g. of plaster of Paris. 60 c.c. of this solution, after clarification, is filtered, shaken with 12 c.c. of N/10 sulphuric acid, diluted with 12 c.c. of water, and 20 c.c. of this mixture titrated with N/10 sodium hydroxide. The percentage of alkaloid is equal to $(10 - \text{c.c. } N/10 \text{ NaOH})3.61 \div 5$.—W. J. W.

Quinine; Determination of —. C. Bamberger. Pharm. Zentr., 1920, 61, 257–259, 267–270.

THE following method yields results which agree with those obtained by the Swiss Pharmacopœia method which is known to be trustworthy (the German Pharmacopœia method is unreliable):—25 g. of cinchona bark is warmed on a water-bath for 10 mins. with 2 c.c. of hydrochloric acid and 20 c.c. of water, then cooled and shaken with a mixture of 25 g. of chloroform and 50 g. of ether. 5 g. of sodium hydroxide is then added, the mixture shaken thoroughly for 3 mins., and 50 g. of crystallised calcium sulphate is added; when this has settled, 60 g. of the clear chloroform-ether solution is transferred to a separating funnel and shaken out twice with 5 c.c. of N/10 hydrochloric acid and twice with 10 c.c. of water. The united extracts are titrated with N/10 potassium hydroxide solution, using methyl-red as indicator. (Cf. Frerichs and Mannheim, J., 1915, 1070; Rapp and Dietrich, J., 1918, 336A.)—W. P. S.

Solvarsan; Composition of —. R. G. Fargher and F. L. Pyman. Chem. Soc. Trans., 1920, 117, 370–377.

SALVARSAN precipitated from methyl alcoholic solution by means of ether contains no combined methyl alcohol as suggested by Kober (J. Amer. Chem. Soc., 1919, 41, 442). When precipitated by means of acetone, however, it contains one molecular proportion of that substance. Commercial solvarsan contains a considerable proportion of sulphur, 2–3% in extreme cases, which is not disclosed in the reputed formula. The authors consider that, at least in part, this occurs in the form of a sulphamma-group, $-\text{NH}_2\text{SO}_2\text{H}$, whilst some may be directly attached to arsenic, or be present in physical association with the solvarsan. Pure solvarsan, as distinct from the commercial product, was obtained by the reduction of 3-nitro-4-hydroxyphenylarsinic acid in alkaline solution with just sufficient hydrosulphite to reduce the nitro-group. The resulting amine was purified by the method of Ehrlich and Berthelm (J., 1912, 407) and was further reduced to the arsenobenzene by means of hypophosphorous acid in presence of potassium iodide as a catalyst, the precipitated base being then converted into its dihydrochloride.—G. F. M.

Arsanilic acid; Preparation of primary —. H. C. Cheetham and J. H. Schmidt. J. Amer. Chem. Soc., 1920, 42, 828–829.

By heating a mixture of dry arsenic acid (4 g.-mol.) and aniline (1 g.-mol.) for 12 hrs. at 150°–160° C. a good yield of arsanilic acid (26% of the pure recrystallised substance) can be obtained and 90% of the excess aniline can be easily recovered.—J. K.

Arsenic; Organic compounds of —. A. McKenzie and J. K. Wood. Chem. Soc. Trans., 1920, 117, 406–415.

ETHOXYDICHOROARSINE, b.p. 145°–146° C. at 751 mm., and diethoxychloroarsine, b.p. 64°–65° C. at 20 mm., were obtained by the action of one and two mols. respectively of sodium ethoxide on arsenious chloride. Ethyldichloroarsine was obtained from arsenious oxide through ethyldiiodoarsine and ethylarsenious oxide. For the preparation of diphenylethanoarsine, diphenylchloroarsine was treated with sodium hydroxide solution, whereby an almost theoretical yield of diphenylarsenious oxide was obtained. This was heated at 120°–160° C., and dry hydrogen cyanide was passed into the molten material for 5 hrs. The yield of crude product is almost theoretical. The pure substance has m.p. 31°–32° C.—G. F. M.

Benzoic acid and its derivatives; Volatility of — in steam. N. V. Sidgwick. Chem. Soc. Trans., 1920, 117, 396–406.

THE volatility in steam of benzoic acid and some of its derivatives was determined by passing steam through a mixture of the acid and water contained in two 120 c.c. flasks heated in a glycerin bath and arranged in series with one another and with a Kjeldahl trap leading to the condenser. The steam connections, the upper parts of the flasks, and the trap were all lagged to prevent condensation. The following are some of the results:—

	Percentage in distillate.	Vapour pressure in mm. × 100.	Relative vap. pressure.
Benzoic acid ..	1.006	112.9	1.0
Phenylacetic acid ..	0.294	29.55	0.262
Toluic acid—ortho ..	0.964	97.0	4.49
—meta ..	0.604	60.7	2.81
—para ..	0.215	21.6	1.0
Hydroxybenzoic acid—ortho ..	0.400	39.7	1320.0
—meta ..	0.0015	0.149	5.0
—para ..	0.0003	0.030	1.0

The relative vapour pressure above is referred to the *para*-acid as unity, except that phenylacetic acid is referred to benzoic acid.—G. F. M.

Chlorobenzenes; Analysis of industrial —. F. Bourion and C. Courtois. Comptes rend., 1920, 170, 1115–1117.

THE method previously given (J., 1920, 425 A) for the analysis of industrial chlorobenzenes is slightly modified to allow of a more accurate determination of the percentage of polychlorobenzenes. A sample of the chlorobenzene is distilled at 160° C. and the density at 40° C. of the residue which does not pass over is determined. By means of this value and formulæ given it is possible to calculate the percentage of polychlorobenzenes present.—W. G.

Methyl chlorosulphonate; Action of water on —. J. Guyot and L. J. Simon. Comptes rend., 1920, 170, 326–328.

THE action of water on methyl chlorosulphonate is regulated by three main changes, thus:—

there being under some conditions two subsidiary changes:—

The final equilibrium depends on the relative amounts of water and chlorosulphonate present. The primary change is the one which produces methyl hydrogen sulphate, but with excess of water this compound is further decomposed, this latter action being, however, reversible. When the amount of water diminishes the concentration of the acids becomes important, the esterification of the methyl alcohol, with the consequent formation of methyl chloride, becoming the most important change.—W. G.

Halogenhydrins; Preparation of —. J. Read and M. M. Williams. Chem. Soc. Trans., 1920, 117, 359–362.

CHLORINE or bromine water may be used as a source of hypochlorous or hypobromous acid for the preparation of halogenhydrins from ethylenic compounds. Ethylene bromohydrin, for example, is obtained by leading ethylene and air saturated with bromine vapour through two perforated bulbs fixed a short distance apart in ice-cooled water which is kept in continual agitation. The operation may be continued until the solution contains over 14% of bromohydrin. A proportion of ethylene dibromide, corresponding to about 27% of the bromine used, is formed as a by-product, but in the case of the chlorohydrin the amount of dichloride formed appears to be substantially less (*cf.* Gomberg, J., 1919, 923 A).—G. F. M.

Ethers; Catalytic preparation by the dry way of certain —. A. Mailhe and F. de Godon. Bull. Soc. Chim., 1920, 27, 328–330. (See J., 1919, 926 A; 1920, 247 A.)

ALLYL alcohol vapour when passed over calcined alum at 185°–190° C. gives a 30% yield of allyl ether. If the allyl alcohol is mixed with methyl alcohol or its higher homologues the main product is still allyl ether, although a certain amount of the mixed ether is obtained. (*Cf.* J.C.S., July.)

—W. G.

Amines; Preparation of — by catalysis. A. Mailhe. Comptes rend., 1920, 170, 1120–1123.

ALDAZINES undergo hydrogenation when passed with hydrogen over reduced nickel at 140°–160° C., giving the corresponding primary and secondary amines, the relative proportions of the two amines obtained varying with the temperature of hydrogenation and the aldzine used. The method has been applied to the preparation of ethyl-, isobutyl-, and isoamyl-amines.—W. G.

Hydrogenation; Catalytic — with protected hydrosols. E. K. Rideal. J. Amer. Chem. Soc., 1920, 42, 749–756.

PROTECTING colloids, such as gum arabic, function as peptising agents in catalytic hydrogenation by colloidal platinum and palladium. The addition of a little colloidal palladium to colloidal platinum greatly enhances the activity of the latter. (*Cf.* J.C.S., ii., 364.)—J. F. S.

Catalytic actions at solid surfaces. III. Hydrogenation of acetaldehyde and the dehydrogenation of ethyl alcohol in the presence of finely divided metals. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1920, A, 97, 259–264. (*Cf.* J., 1919, 780 A; 1920, 163 A.)

ACETALDEHYDE is converted into ethyl alcohol, when passed with hydrogen over finely divided copper or nickel at 120°–300° C. With copper the yield of alcohol is 87.6% at 200°, and 33.7% at 300° C., whilst with nickel at 120°–150° C. it is 53.6%. In the presence of copper at 295°–300° C. a yield of 95% aldehyde may be obtained from alcohol. The presence of a little water in the alcohol improves the yield of aldehyde relatively to that of hydrogen. Small quantities (1–2%) of by-products, *n*-butyric aldehyde, crotonic aldehyde, and ethyl acetate, are always obtained. The presence of small quantities of water protects aldehyde from hydrogenation and in some cases entirely prevents the reaction. (*Cf.* J.C.S., July.)—J. F. S.

Methyl alcohol; Determination of —. S. B. Schryver and C. C. Wood. Analyst, 1920, 45, 164–170.

THE method proposed consists essentially in de-

termining the concentration of ammonium persulphate necessary to destroy completely the formaldehyde formed in the initial stages of the oxidation process under specified conditions of experiment. The formaldehyde is detected by treating the solution with 1% phenylhydrazine hydrochloride solution, then adding potassium ferri-cyanide and concentrated hydrochloric acid; a brilliant red coloration is produced and the test will detect as little as 1 part of formaldehyde in 2,000,000. To determine methyl alcohol in aqueous solution, portions of 5 c.c. each of the solution (which may contain from 0.0005 to 1% of the alcohol) are placed in a series of test-tubes, 5 c.c. of ammonium persulphate solution of varying concentration (0.01 to 5%) is added, the mixtures are heated at 100° C. for 10 mins., and 1 c.c. of each mixture is then tested for formaldehyde. A second series of oxidations is then made, using 5 c.c. of the alcohol solution with 5 c.c. of persulphate solution in concentrations varying between the limits of concentration found in the first test at which the oxidation of the formaldehyde was complete and not complete respectively. For each concentration of methyl alcohol there corresponds a definite concentration of persulphate to oxidise all the formaldehyde; these concentrations are given in tabular form. If c is the concentration (%) of the persulphate and x that of the methyl alcohol, and k a constant, then $x = kc$; experiments with pure methyl alcohol show that $k = 0.059$. The method, with slight modification, is applicable to the determination of methyl alcohol in acetone; in this case the amount of methyl alcohol present must be not less than 4%. There is no preferential oxidation of methyl alcohol in a mixture of this with ethyl alcohol, but in such a mixture the methyl alcohol may be determined by oxidising the mixture partially with a relatively small amount of persulphate (the alcohols being in excess) and determining colorimetrically the formaldehyde formed under these conditions. Ten c.c. of the ethyl alcohol containing methyl alcohol is diluted with 50 c.c. of water and 5 c.c. of this solution is heated in a boiling water-bath for 10 mins. with 5 c.c. of 1% ammonium persulphate solution; 1 c.c. of the mixture is then mixed with 1 c.c. of phenylhydrazine hydrochloride solution, heated in a boiling water-bath for 5 mins., cooled, treated with 1 c.c. of 2.5% potassium ferri-cyanide solution and 3 c.c. of concentrated hydrochloric acid, and the coloration compared with standards prepared, under similar conditions, with ethyl alcohol containing known amounts of methyl alcohol.—W. P. S.

Acetates; Systematic detection of —. L. J. Curtman, D. A. Broggi, and V. Fourman. *Chem. News*, 1920, 120, 230—231.

To detect acetates in mixtures the authors recommend the following procedure: The solution is acidified with nitric acid, treated with silver nitrate, and filtered. The filtrate is made just alkaline with caustic soda, a solution of barium and calcium chlorides added, and the precipitate filtered off. The clear liquor is concentrated to 5 c.c. after addition of hydrogen peroxide. After filtering off the deposited crystals the solution is made just neutral to phenolphthalein with dilute hydrochloric acid, 1 c.c. of ferric chloride solution is added, and the colour compared with that of controls prepared with 1 c.c. of ferric chloride solution in 5 c.c. of water and known quantities of sodium acetate. A reddish-yellow colour is perceptible if as little as 2 mg. of acetic acid is present. Acetates may also be recognised by the odour of the vapour evolved on boiling 1 c.c. of the test solution with 2 c.c. of sulphuric acid (1:1). The test is sensitive to 2 mg., but nitrates seriously interfere. (*Cf.* J.C.S., ii., 393.)—A. R. P.

Juniperus oxycedrus oil; Chemical characters of —. R. Huero. *J. Pharm. Chim.*, 1920, 21, 347—352.

Juniperus oxycedrus oil has acid value, 0.46—I37; saponif. value, 2.9—5.0; iodine value (Hübl), 179; free alcohols (extracted by phthalic anhydride), 12—14; acetyl value, 38.7—30.5. Whilst the total amount of bromine absorbed by the oil varies with the excess of bromine added, the bromine combining as an addition product with the formation of hydrobromic acid is a more constant quantity and ranges from 34 to 38 g. per 100 g. of oil.—W. P. S.

Halogen in organic substances. Van Winkle and Smith. See XXIII.

PATENTS.

Acetic anhydride; Manufacture of —. H. Dreyfus. U.S.P. 1,338,979, 4.5.20. Appl., 4.2.19.

In the process where gaseous sulphuric anhydride reacts at a low temperature with a dry acetate the sulphuric anhydride is mixed with an indifferent gaseous diluent. (*Cf.* E.P. 17,920 of 1915; J., 1917, 162.)—A. E. D.

Alkaline-earth salts of organic acids; Manufacture of water-soluble —. A. Herzfeld and G. Lénárt. G.P. 303,282, 19.2.16.

A MIXTURE of organic and inorganic acids obtained by the oxidation of a carbohydrate is treated with sufficient alkali hydroxide to neutralise the inorganic acid, and the organic acid is then neutralised by the addition of an alkaline-earth oxide or hydroxide. The alkaline-earth salt of the organic acid is then recovered from the solution by crystallisation. (*Cf.* J., 1920, 205A.)—L. A. C.

Tannin-albumin compound; Process for preparing a — from blood. Knoll und Co. G.P. (a) 305,693, 4.9.17, and (b) 317,675, 7.3.18.

(a) BLOOD is precipitated with a quantity of tannin equal to the total content of albuminous matter, including the hæmoglobin. The precipitate is drained, dried, and, if desired, subjected to a temperature above 100° C., and preferably treated with dehydrating agents, e.g., alcohol or hydrochloric acid. A light-coloured product is obtained which is free from both the colour and taste of the blood. (a) BLOOD is decolorised by means of a bleaching agent or coagulated and the albumins filtered off, washed, dried, and treated with a tannin solution, or they may be treated with tannin before filtration. In both cases the precipitate gradually adsorbs as much tannin from the solution as is contained in the tannin-albumin compound obtained as described under (a). The product has a light-grey colour.—D. W.

Organic derivatives of calcium iodide; Manufacture of —. W. Spitz. G.P. 318,343, 11.3.16.

STABLE, non-deliquescent compounds of therapeutic value are prepared by mixing aqueous or alcoholic solutions of calcium iodide and of a free or combined amino-acid or urea; double compounds of the two constituents separate from the solution by crystallisation or evaporation. Examples are: Glycocoll calcium iodide, $\text{CaI}_2(\text{CH}_2\text{NH}_2\text{COOH})_2 \cdot 2\text{H}_2\text{O}$, white, prismatic needles, decomp. above 275° C. without melting; urea calcium iodide,

white tables, m.p. 167.5° C.; glycylglycine calcium iodide, $(\text{C}_2\text{H}_5\text{N}_2\text{O}_2)_2 \cdot \text{CaI}_2 \cdot 2\text{H}_2\text{O}$, white needles, decomp. above 200° C.; alanine calcium iodide, $(\text{C}_3\text{H}_7\text{NO}_2)_2 \cdot \text{CaI}_2 \cdot 2\text{H}_2\text{O}$, m.p. 115° C.—L. A. C.

Paraldehyde; Production of —. Konsortium für Elektrochem. Ind. G.P. 319,368, 30.8.17.

AFTER the conversion of acetaldehyde into paraldehyde

hyde by acid catalysts, these acids are removed by treating the cooled reaction product with an excess of the solid salt of a weak acid, such as a fatty acid or boric acid. In this way the formation of aldol or crotonaldehyde can be avoided, whilst the paraldehyde and unaltered aldehyde can be removed and separated by distillation.—D. F. T.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic science; Studies in —. H. J. Channon. Phot. J., 1920, 60, 164—173.

THE effect of intensity variation on contrast is not regular but is a function of the plate. With very weak intensities the maximum density obtainable with very prolonged exposures is a function of the intensity and of the plate, but is generally much smaller than the density obtainable by an equal exposure of short duration and high intensity. Reversal can be produced by continued exposure to a weak intensity after production of a latent image by normal exposure. A similar reversal can be produced by exposure to (not necessarily contact with) metallic zinc, with the difference that if reversal is produced by light action the plate sensitiveness is destroyed, but not if reversal is produced by zinc. The production of a positive by development in white light is shown to be partly due to the screening effect of the image first formed, and partly due to an actual loss of sensitiveness by the exposed and partially developed film. A number of experiments are described, for details of which the original paper should be consulted.—B. V. S.

Photographic sensitisers; Studies on —. I. The isocyanine dyestuffs. W. H. Mills and W. J. Pope. Phot. J., 1920, 60, 183—198.

SEVERAL members of the isocyanine class of dyes, produced by the condensation of 1 mol. of a quinaldinium alkyl-iodide with 1 mol. of a quinaldinium alkyl-iodide have found important use as colour-sensitisers of photographic emulsions, the best-known being Pinaverdol (British, Sensitol Green). Their general constitution is probably best represented by the formula $(R)N.C_6H_4(4):CH.(2)C_6H_4.N(R)I$ (see also Mills and Wishart, Trans. Chem. Soc., 1920, 117, 579—587). The preparation and properties of 20 isocyanines are described, all of them having been examined as to their sensitising effect on photographic plates by bathing in a solution of 1:75,000. The parent body (1,1'-dimethylisocyanine iodide) is a strong sensitiser, sensitising up to about 6400; the introduction of a third methyl into the 6-position gives a still stronger sensitiser (Pinaverdol). The replacement of the first two methyl groups by heavier groups (ethyl, *n*-propyl, and *n*-butyl) reduces the sensitising effect in increasing amount. The introduction of a third methyl group into the 6'-position reduces the sensitising effect, as does also the introduction of two more methyl group into the 2'- and 6-positions, or of a cyano or phenyl group into the 2'-position. The 1,1'-diethyl compound (Ethyl Red) is similar to the 1,1'-dimethyl compound, but a somewhat weaker sensitiser, and the addition of

other radicles into it has a similar effect. The introduction of the amino-group into the 5-, 6-, or 6'-position in 1,1'-dimethylisocyanine iodide increases the sensitising power to about the same extent in each case, but the introduction of the acetamino group has only a slight depressing effect; in the 6'-position, stronger in the 6-position, and very strong in the 5-position. The effect of the cinnamoyl-amino group in the 6-position is less than that of the acetamino group. The 1,1'-diethyl-6'-ethoxy-6'-methoxy compound is a strong sensitiser, corresponding with the German Pinachrome.

—B. V. S.

PATENTS.

Motion-picture film. W. V. D. Kelley, Assr. to Prizma, Inc. U.S.P. 1,337,775, 20.4.20. Appl., 8.7.18.

A FILM is provided on both sides with a sensitive emulsion containing a symmetrical design in insensitive material. Colour-sensation negatives are printed on both sides and the positives stained in suitable colours to give natural colours additively.

—B. V. S.

Actinometers. E.P. 141,825. See XXIII.

XXII.—EXPLOSIVES; MATCHES.

Nitroglycerin manufacture; Process for reducing the loss of nitric acid and glycerin in —. F. Hofwimmer. Z. ges. Schiess- u. Sprengstoffw., 1919, 14, 361—366, 381—383, 393—395. Chem. Zentr., 1920, 91, II., 620—621.

IN the production of nitroglycerin about 15% of glycerin is lost, owing to the solubility of the three-nitrates in the waste acid and wash-waters. Ten experimental runs were made in which the only variables were the proportions of glycerin and nitration acid. After a normal nitration the waste acid contains 0.7—0.8% of nitroglycerin. By mixing it with an equal quantity of 20% oleum it may be used for the manufacture of nitric acid. It is advisable to neutralise even the first wash water with soda in order to reduce the amount of dinitrate dissolved. Tables are given showing comparative figures for yields of tri- and dinitrate, temperatures, and amount of soda used. The neutralisation process showed a gain of 30—40% as regards time and consumption of compressed air, and of 60—80% of water. The life of the plant was also considerably extended.—W. J. W.

Nitrocellulose; German stability tests and a new hot storage test (75° C.) for —. F. Lenze and B. Plens. Z. ges. Schiess- u. Sprengstoffw., 1919, 14, 377—380, 395—399. Chem. Zentr., 1920, 91, II., 622. (Cf. J., 1920, 281 A.)

EXAMINATION by the manometric and the NO methods of 7 samples of collodion cotton and 6 samples of gun-cotton, which had considerably deteriorated after 13—15 years' storage in a magazine and 1—4½ years' exposure in the open gave no clear indication of their relative stability. The hot storage test, on the other hand, gave satisfactory results. The presence of unstable portions in gun-cotton cannot always be determined with certainty, but in this respect the hot storage test again is the most reliable.—W. J. W.

Mercury fulminate; By-products in the manufacture of —. A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1919, 14, 366—369, 399—402. Chem. Zentr., 1920, 91, II., 621—622. (Cf. J., 1920, 281 A.)

CRYSTALS are formed chiefly in the curved pipe leading to the coke-tower. They probably consist of a non-explosive double salt of mercurous nitrate

and an oxide of mercury. The condensation product in the receivers is similar to the crystals. White needles of variable composition are produced by precipitation of the condensation liquors with hexamethylenetetramine. It is not possible to separate the mercury entirely from the liquors. With 10% "formin" solution a compound of "formin" and mercurous nitrate is formed. In the estimation of the nitric acid in the liquors by means of nitron, the results differ by 2–3% from those obtained by titration. Greater accuracy is secured by a preliminary evaporation of the neutralised condensation liquors, by which means organic compounds, esters, etc., are precipitated.—W. J. W.

Recovery of nitrous gases. Walker. See VII.

PATENTS.

Cellulose; Nitration of —. C. Claessen. G.P. 298,418, 3.11.15.

CELLULOSE is mercerised by means of sodium hydroxide, washed, and dried, the material being then unravelled before nitration.—W. J. W.

Coloured smoke. E. C. Weisgerber. U.S.P. 1,339,142–50, 4.5.20. Appl., 10.1.19.

COLORLED smoke-producing compositions are composed of potassium chlorate and lactose together with ammonium iodide and iodine; iodine; litharge and iodine; lead iodide; copper iodide and iodine; ammonium iodide, iodine, and magnesium; mercury sulphide, cobalt oxide, and iodine; mercurous iodide; or naphthalene.

Artificial clouds, fogs, or mists; Process and apparatus for production of intense —. P. Weiss and J. Verdier. U.S.P. 1,338,343, 27.4.20. Appl., 10.12.17.

SEE E.P. 127,289 of 1916; J., 1919, 553 A.

XXIII.—ANALYSIS.

Potassium chlorate as a standardising substance for solutions of alkali. H. B. Van Valkenburgh. J. Amer. Chem. Soc., 1920, 42, 757–760.

POTASSIUM chlorate is a suitable substance for standardising solutions of alkali. The chlorate is dried at 240° C. for 4–6 hrs., dissolved, the solution boiled in an Erlenmeyer flask and sulphur dioxide passed in for 30 mins., boiling being continued for a further 10 mins. to expel the excess of sulphur dioxide. Phenolphthalein is added and the solution titrated, either hot or cold, with alkali. The calculation of the strength of the alkali is based on the equation: $\text{KClO}_3 + 3\text{SO}_2 + 3\text{H}_2\text{O} = 3\text{H}_2\text{SO}_4 + \text{KCl}$.—J. F. S.

Carbon; Determination of — [in organic substances]. L. Lescoeur. J. Pharm. Chim., 1920, 21, 257–263.

A QUANTITY of the organic substance, e.g., sugar, oxalic acid, sodium acetate, urea, etc., containing 0.05–0.2 g. of carbon, is mixed in a covered silver crucible with 10 g. of a mixture of equal weights of sodium nitrate and potassium nitrate, and a

quantity of N/2 sodium hydroxide solution (free from carbonate) is added so that at least 10 mols. of NaOH are present for each atom of carbon. The mixture is dried and then fused until all carbon has been oxidised. After cooling the mass is dissolved in hot water, ammonium chloride and calcium chloride are added, and the precipitated calcium carbonate is collected, washed, and titrated with N/1 hydrochloric acid, using methyl orange as indicator.—W. P. S.

Manganese; Different methods of estimation of — and their use in the examination of plant ashes and similar products. D. H. Wester. Rec. Trav. Chim., 1920, 39, 414–422.

OF four colorimetric methods for the estimation of traces of manganese examined only Marshall's method (Chem. News, 1901, 76), in which the manganese is oxidised to permanganate by potassium persulphate, was satisfactory. This method is not vitiated by the presence of small amounts of nitric or sulphuric acid or silver nitrate, and the amount of persulphate used is without influence. During the process of oxidation the heating on a water bath should not exceed 30 mins. The presence of salts likely to be found in plant ashes does not interfere with the estimation, although it is preferable to remove chlorides by a preliminary evaporation with sulphuric acid. The presence of more than 0.05 g. of ferrie salts per 100 c.c. makes it impossible to carry out the colorimetric comparison.—W. G.

Potash; The De Roode-perchloric acid method for determining —. T. E. Keitt. J. Ind. Eng. Chem., 1920, 12, 276–277.

SULPHATES are removed by treating the hot solution of the sample with hydrochloric acid and a slight excess of barium chloride; the solution is then cooled, diluted to a definite volume, and an aliquot portion of the clear liquid is evaporated several times to dryness with the addition of *aqua regia*. The residue is dissolved in 20 c.c. of hot water, 5 c.c. of perchloric acid (sp.gr. 1.12) is added, the mixture evaporated on a hot-plate until copious fumes are given off, and then cooled. The residue should be solid when cold; it is again evaporated with the addition of water and perchloric acid, the residue, when cold, treated with 20 c.c. of 95% alcohol, stirred, and the insoluble portion collected after 30 mins. on a weighed asbestos filter, washed twice with alcohol containing 0.2% of perchloric acid, then twice with alcohol-ether (1:1), dried at 120° C., and weighed. The weight of the residue is multiplied by 0.34 to obtain the amount of K_2O present.

—W. P. S.

Iodic acid as a microchemical reagent for soluble and insoluble compounds of calcium, strontium, or barium. G. Deniges. Comptes rend., 1920, 170, 996–998.

If a drop of an aqueous solution of a soluble salt of calcium, strontium, or barium, or a suspension of a finely divided insoluble salt in a drop of water is placed on a microscope slide and one drop of a 10% aqueous solution of iodic acid is added a crystalline precipitate, characteristic for each of the metals, is formed and may be observed under a microscope. If barium is present as the sulphate, this salt should first be reduced to the sulphide in a reducing flame before applying the test. Calcium iodate or periodate should be ignited and the test applied to the resulting iodide.—W. G.

Chromium; Influence of atmospheric oxygen on the iodometric determination of —. O. Meindl. Z. anal. Chem., 1919, 58, 529–548.

ATMOSPHERIC oxygen reacts with the hydriodic acid-chromic acid mixture and causes the results obtained in the iodometric determination of chromium

to be too high. The error increases with increase in the time of contact.—W. P. S.

Tin and antimony; Separation of —. Estimation of tin by cupferron. A. Kling and A. Lassieur. *Comptes rend.*, 1920, 170, 1112—1114.

THE solution of the two metals (0.3–0.4 g. at the most) in hydrochloric acid and potassium chlorate is neutralised with sodium hydroxide in the presence of methyl orange. It is then acidified with hydrochloric acid, and 5–6 g. of tartaric acid is added and the solution warmed till perfectly clear. After cooling the solution is transferred to a conical flask lined with wax, treated with 10 c.c. of hydrofluoric acid, and after $\frac{1}{2}$ hr. 10 g. of sodium acetate is added, and the solution is diluted to 300 c.c. The antimony is then precipitated as antimony sulphide, which is filtered off, washed, dissolved in hydrochloric acid and potassium chlorate, and subsequently re-precipitated, collected, dried at 300° C. in a current of carbon dioxide and weighed. 10 g. of boric acid is added to the filtrate from the first precipitation of the antimony sulphide, and the solution is boiled with a little hydrogen peroxide. After cooling a 10% solution of cupferron is added, and the white precipitate which forms is filtered off, washed with cold water, dried, and calcined, the tin being weighed as stannic oxide.—W. G.

Cupferron; Use of — in quantitative analysis. G. E. F. Lundell and H. B. Knowles. *J. Ind. Eng. Chem.*, 1920, 12, 344–350.

ALTHOUGH cupferron (nitrosophenylhydroxylamine ammonium) has been used successfully for the separation of iron from manganese, and iron and titanium from aluminium and manganese, and for the determination of copper, iron, titanium, zirconium, thorium, and vanadium, the methods are subject to the action of so many interfering substances that they offer little advantage over the usual well-known methods.—W. P. S.

Nitrosophenylhydroxylamine (cupferron); Salts of —. Uranous salt. V. Auger. *Comptes rend.*, 1920, 170, 995–996.

IN neutral solution cupferron precipitates all the metals except the alkalis, the salts obtained being either simple salts, insoluble in chloroform and decomposed by dilute acids or complex salts, soluble in chloroform and more or less resistant to strong acids. Uranyl salts do not give a precipitate with cupferron, but if they are first reduced with zinc in acid solution then the whole of the uranium is precipitated as a uranous salt, $(C_6H_5N_2O)_4U$, crystallising from chloroform in brown prisms. By this means vanadium and uranium may be separated by successive precipitation.—W. G.

Uranium; Estimation of —. R. Schwarz. *Helv. Chim. Acta*, 1920, 3, 330–346.

AMMONIUM sulphide and ammonia are the simplest and most reliable precipitants for uranium. The former is best employed at 80° C. in presence of ammonium chloride; some ammonium uranate is always formed, and complete separation from alkali metals is only attained by repeating the precipitation. Precipitation with ammonia should be performed at 100° C. in presence of ammonium chloride, and preferably not in glass vessels owing to the tendency of ammonium uranate to carry down silica with it. The precipitates are best weighed as uranosouranic oxide, ignition being carried out in porcelain crucibles with access of air rather than in platinum. The uranyl phosphate method of separation from alkali metals is unsatisfactory owing to the fineness of the precipitate. Of volumetric processes, good results are obtained by the solution of uranosouranic oxide in sulphuric acid, but not by attempting complete reduction to uranous salts. Uranium in presence of aluminium

is best determined titrimetrically. Aluminium is incompletely precipitated by ammonium carbonate in presence of ammonium chloride, and some uranium is carried down; good results are, however, obtainable by this method by following a complicated procedure which is described. The separation of iron from uranium by ammonium carbonate and ammonium sulphide is quite effective. Chromium salts must first be oxidised to chromates, preferably by alkaline hypobromite, alternatively by ammonium persulphate. Sodium uranate, when precipitated in presence of chromates, always contains uranyl alkali chromates; the precipitation must therefore be repeated, and it is also advisable to redissolve the uranosouranic oxide finally obtained in nitric acid to separate it from silica. Evidence is given in favour of the existence of the oxide, U_2O_3 , and its formation by heating uranosouranic oxide at 112° C. in a stream of carbon dioxide. (*Cf. J.C.S.*, June.)—J. K.

Halogen in organic substances; Determination of —. W. A. Van Winkle and G. McP. Smith. *J. Amer. Chem. Soc.*, 1920, 42, 333–347.

THE sample is volatilised in a current of air, and the vapour is passed through a quartz tube heated for a length of about 25 cm. to 900°–1000° C. The products of combustion pass to an absorption tube through which is kept flowing a mixture of 25 c.c. of 5N sodium hydroxide solution and 10 c.c. of 2N sodium sulphite. The sulphite serves to reduce any oxyhalogen salts which may be formed. The time taken for a combustion is 1–2 hrs. The excess of sulphite in the absorbing solution is oxidised with potassium permanganate and the halogen is determined by the Volhard process. With ethyl bromide and iodide, ethylene chloride, allyl bromide, chloroform, chloropierin, bromobenzene, etc., results equal or superior to these obtained by the Carius method were obtained. A slightly modified form of the process can be used for less volatile substances, such as hexachlorobenzene, *m*-chloronitrobenzene, and *p*-bromoaniline.—E. H. R.

Nitrogen in organic compounds; Detection of —. Castellana's reaction. J. Flieringa. *Pharm. Weekblad*, 1920, 57, 3–4.

A POSITIVE reaction may be obtained with nitrogen-free compounds in Castellana's reaction (heating substance with alkali carbonate and magnesium and testing for cyanide; *Gaz. Chim. Ital.*, 1904, 34, ii., 357) if the magnesium is in excess owing to combination of atmospheric nitrogen. The proportion of sodium carbonate to magnesium should be 2:1, and the monohydrated carbonate should be used. Sugar should be added to the mixture to eliminate error due to combined atmospheric nitrogen.

—W. J. W.

Mineral constituents in organic substances; Determination of — especially in those containing phosphorus. J. Grossfeld. *Chem.-Zeit.*, 1920, 44, 285–286.

CERTAIN substances, *e.g.*, proteins, blood, etc., burn with difficulty, and the ash contains unburnt carbon. If, however, the substance is mixed previously with magnesium acetate solution and dried, it burns readily, yielding a white ash, and there is no loss of phosphorus. Allowance must be made for the quantity of magnesia added as magnesium acetate.—W. P. S.

Gas analysis; Automatic methods of — depending on thermal conductivity. E. R. Weaver, P. E. Palmer, H. W. Frantz, P. G. Ledig, and S. F. Pickering. *J. Ind. Eng. Chem.*, 1920, 12, 359–366.

THE method described depends on the fact that when a wire surrounded by a gas is traversed by a constant electrical current under conditions where

all loss of heat except by conduction through the gas is excluded, the wire attains a temperature equilibrium depending on the thermal conductivity of the gas. If the wire has a high temperature coefficient of electrical resistance, its resistance will have a value corresponding to the thermal conductivity of the surrounding gas and, therefore, to the composition of the latter. The apparatus, in which a balanced bridge is adopted, consists of two similar tubes, not more than 1 cm. in diameter, bored in a brass rod; each chamber thus formed has a platinum wire stretched down its centre, and the necessary electrical connexions and gas inlets and outlets are provided. One chamber serves for the gas under examination and the other for a comparison gas. The apparatus may be adapted for automatic recording.—W. P. S.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Anderson and Meikle. Treatment of blast-furnace tar. 14,567. May 28.
 Duckham, Morgan, and Thermal Industrial and Chemical Research Co. Stills for distilling tar, oils, etc. 14,379. May 26.
 Granger and others. 15,126. See II.
 Kinzberger and Co. Purification of anthraquinone. 14,457. May 27. (Austria, 20.9.17.)
 Kinzberger and Co. Purification of crude anthracene. 15,354 and 15,454. June 7 and 8. (Austria, 30.10.16 and 31.3.17.)
 Medsforth, and South Metropolitan Gas Co. Purification of anthraquinone. 14,275. May 25.
 Pestalozzi. Producing tar of aliphatic compounds or low-temperature tar. 15,651. June 9. (Switz., 20.6.19.)
 Stanier, and South Metropolitan Gas Co. Manufacture of naphthylamine sulphonic acids. 14,276. May 25.

COMPLETE SPECIFICATIONS ACCEPTED.

19,686 (1918). Barrett Co. Process of sulphonating benzene. (122,169.) June 9.
 8643 (1919). Jackson (Twitchell Process Co.). Alkali metal sulphonate. (143,683.) June 9.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Badische Anilin u. Sodafabrik. Manufacture of yellow colouring matters for dyeing animal fibres. 15,457. June 8. (Ger., 14.4.14.)
 Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of ortho-oxy-azo dyestuffs. 15,515. June 8.
 Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of azo dyestuffs for wool. 15,637. June 9.
 Farbenfabr. vorm. F. Bayer und Co. Manufacture of azo dyestuffs. 15,133. June 3. (Ger., 16.7.18.)
 Imray (Monsanto Chemical Works). Manufacture of phthaleins. 14,767. May 31.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Arent. Treating materials to reduce inflammability. 15,946. June 12. (U.S., 26.6.19.)

Atomized Products Corp. Treating waste sulphite liquors. 14,387. May 26. (U.S., 16.11.18.)
 Bronnert. Manufacture of artificial silk. 14,632. May 28.
 Dreaper. Manufacture of artificial threads or filaments. 14,314. May 26.
 Dreyfus. Manufacture of cellulose products. 15,736. June 10.
 Levy. Production of artificial filaments. 15,780. June 10.
 Soc. Chim. des Usines du Rhône. Manufacture of cellulose esters. 15,104. June 3. (Fr., 20.6.19.)
 Sutherland. Making pulp board. 15,370. June 7.

COMPLETE SPECIFICATIONS ACCEPTED.

13,529 (1919). Kashtani. Treating cotton yarn or cotton cloth. (144,083.) June 16.
 31,188-9 (1919). Gillet et Fils. Treatment of vegetable fibres. (136,833 and 144,204.) June 9 and 16.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Bloxham (Act.-Ges. f. Anilinfabr.). Dyeing skins, hairs, feathers, etc. 15,636. June 9.
 Butterfield. Compound for stiffening and proofing textile fabrics etc. 15,502. June 8.
 Drey and Moseley. Detergents and bleaching compounds etc. 15,393. June 8.
 Jowett. Printing etc. processes for textile fabrics. 15,068. June 3.
 Poulson. Sizing textile fabrics etc. 14,820. June 1.
 Straub und Co. Production of coloured ornamental designs on fabrics. 15,677. June 10. (Switz., 1.3.20.)
 Taylor. Bleaching. 15,917. June 12.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

American Smelting and Refining Co. Making sulphur from sulphur dioxide. 15,121. June 3. (U.S., 9.9.18.)
 Badische Anilin u. Sodafabr. 15,458. See XVI.
 Berend, and Chem. Fabr. Dr. K. Albert. Preparing colloidal metals, metalloids, and compounds of same. 15,055. June 3.
 Carbic, Ltd., and Waterhouse. Manufacture of calcium carbide cakes. 15,603. June 9.
 Carpmal (Bayer u. Co.). Furnaces for manufacture of hydrochloric acid and sodium sulphate. 14,466. May 27.
 Carpmal (Bayer u. Co.). 15,191. See IX.
 Danckwardt. Producing anhydrous aluminium chloride. 14,944. June 2.
 Dutt and Dutt. Production of sulphur and calcium from gypsum. 14,827. June 1.
 Norsk Hydro-Elektrisk Kvaelfstofaktieselskab. Absorbing nitrous gases. 15,017. June 2.
 Swinburne. Manufacture of anhydrous chlorides. 15,245. June 5.
 Union Carbide Co. Manufacture of calcium carbide. 14,372-3. May 26. (U.S., 20.1.15 and 15.8.17.)
 Welford. Treatment of shales, residues, clay, or aluminous material. 15,535. June 9.

COMPLETE SPECIFICATIONS ACCEPTED.

5580 (1919). Ross. Obtaining copper sulphate from ores. (143,973.) June 16.
 5904 (1919). Rideal and Tarrant. Synthetic production of ammonia. (143,341.) June 2.
 8881 (1919). Damman. Process for purifying rock salt. (144,022.) June 16.

8952 (1919). Allen. Evaporating plant for brine etc. (144,023.) June 16.
 9784 (1919). Shadbolt and Grainger. Manufacture of ammonium sulphate. (144,030.) June 16.
 19,388 (1919). Soc. Indus. de Prod. Chimiques. Converting sodium monochromate into bichromate or chromic acid. (131,289.) June 2.
 19,978 (1919). Fairrie. Kilns for pyrites. (144,142.) June 16.
 31,688 (1919). Soc. Indus. de Prod. Chimiques. Recovering ammonium sodium sulphate from coke-oven and like gases by the use of sodium bisulphate. (136,833.) June 9.
 31,689 (1919). Soc. Indus. de Prod. Chimiques. Recovery of ammonia from coke-oven and like gases. (136,831.) June 16.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Bailey, and Oven, Kiln, and Saggars Committee of British Pottery Manufs. Fed. Plastic mixture for manufacture of saggars for firing pottery etc. 14,940. June 2.
 Foster and Sankey. Method of ascertaining contraction of earthenware, bricks, etc. during firing, and temperatures at which same were fired. 14,586. May 28.
 Ueda. Glass matting process. 15,973. June 12. (Japan, 30.11.17.)
 Welford. 15,535. See VII.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Carpmael (Bayer u. Co.). Manufacture of solutions of silicic acid and silicate cements, and silicate phosphate cements therefrom. 15,191. June 4.
 Clifton. Concrete. 15,804. June 11.
 Hyde. Treatment of cement, concrete, brick-work, etc. 15,955. June 12.
 Schol. Manufacture of stones etc. by compression from sand etc. 15,331. June 7. (Ger., 25.2.18.)
 Schol. Manufacture of artificial stones. 15,761. June 10. (Ger., 15.2.18.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Anderson and Meikle. 14,567. See II.
 Angel. Treatment and reduction of sulphides, refractory etc. ores. 14,334. May 26.
 Berend and others. 15,055. See VII.
 Braek and Stevens. Rotary furnaces for smelting etc. 14,884. June 1.
 Caspersson. Alloys of iron. 15,007. June 2.
 Cayo and Whiteley. Crucible etc. furnaces. 14,903. June 1.
 Cornelius. Producing zinc or zinc and lead. 14,484. May 27.
 Deuts.-Luxemburgische Bergwerks u. Hütten A.-G., and Klinkenberg. Manufacture of refined steel. 14,698. May 29. (Ger., 3.7.18.)
 Elektro-Osmose A.-G. Flotation process of concentrating ores. 14,625. May 28. (Ger., 29.7.18.)
 Gregory. Manufacture of iron, steel, manganese, ferro-manganese, etc. 14,631. May 28.
 Krupp A.-G. Extracting metals from ores, foundry products, furnace dust, etc. 15,884. June 11. (Ger., 3.6.19.)
 Lawson and Warren. Electro deposition of metals. 15,593. June 9.
 Liebig. Roasting fine granular sulphide ores. 14,597. May 28.
 Metallind. Schiele u. Bruchsalser. Welding aluminium to iron. 15,762. June 10. (Ger., 3.6.18.)

Miles. Alloy. 14,485. May 27.
 Moffat and Sutherland. Reduction of metallic sulphide ores. 15,519. June 8.
 Morgan, and Thermal Industrial and Chemical Research Co. Process for detinning iron. 15,516. June 8.
 Soc. Metallurgique de la Bonneville. Ternary alloys. 14,709. May 29. (Fr., 19.1.20.)
 Spafford. Manufacture of blister steel from wrought iron. 15,419. June 8.
 Trent. Treating ores etc. 15,732. June 10. (U.S., 10.7.19.)
 Tyrrell. Briquetting ores. 14,791. May 31. (U.S., 29.5.19.)
 Vautin. Recovering metals from slags. 14,858. June 1.

COMPLETE SPECIFICATIONS ACCEPTED.

4082 (1919). Stock. Manufacture of grey iron. (143,596.) June 9.
 4622-3 (1919). Wade. See XI.
 5381 (1919). Ayala. Solder for aluminium. (123,993.) June 16.
 5573 (1919). Hole. Electric smelting furnaces. (125,363.) June 16.
 5580 (1919). Ross. See VII.
 6210 (1919). Webster. Method of malleablising cast metal. (143,989.) June 16.
 7636 (1919). Cowper-Coles. Process and apparatus for sherardising. (143,674.) June 9.
 10,141 (1919). Comp. d'Appl. Méc. Steel particularly for ball and roller bearings. (126,289.) June 16.
 11,655 (1919). Musser. Centrifugal amalgamator and method of obtaining metal from ore. (143,383.) June 2.
 16,585 (1919). Luttenschlager. Cementation of iron and steel. (143,746.) June 9.
 16,813 (1919). Cohn. Alloys. (144,119.) June 16.
 21,038 (1919). Deuts. Molybdän-Werke. Production of alloys of iron and molybdenum. (131,896.) June 9.
 27,153 (1919). British Thomson-Houston Co. (General Electric Co.). Alloy steels. (144,185.) June 16.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Elektro-Osmose A.-G. Electro-osmotic separation of substances. 15,775. June 10. (Ger., 8.4.18.)
 Higgins, Pritchard, and United Alkali Co. Manufacture of graphite electrodes. 15,349. June 7.
 Jungner. Primary galvanic batteries and electrodes. 15,924. June 12. (Sweden, 17.6.19.)
 Kilburn (Norske Akt. for Elektrokemisk Industri). Electric furnaces. 15,441. June 8.
 Lawson and Warren. 15,593. See X.
 Lilienfeld, and Metallhank u. Metallurgische Ges. Electrical precipitation of solid materials from gases. 15,746. June 10. (Ger., 6.3.16.)
 Oldham and Oldham. Galvanic batteries. 15,205. June 4.
 Pechkrantz. Manufacture of metallic diaphragms of electrolytic cells. 15,861. June 11. (Switz., 12.6.19.)
 Pouchain. Electric accumulators. 14,500. May 27.
 Webb. Cathodes for electrolyzers. 15,286. June 5.

COMPLETE SPECIFICATIONS ACCEPTED.

3693 (1919). Moore. Electric furnaces. (143,292.) June 2.
 4622-3 (1919). Wade (Central Mining and Investment Corp.). Electrolytic recovery of metals from solutions. (143,619 and 143,620.) June 9.
 5573 (1919). Hole. See X.
 15,439 (1919). British Thomson-Houston Co. (General Electric Co.). Control for electric furnaces. (143,737.) June 9.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Durden. Apparatus for extracting oils from nuts, seeds, etc. 15,887. June 11.
 Elektro-Osmose A.-G. Decolorising liquids containing glycerin. 15,882. June 11. (Ger., 12.2.19.)
 Fry. Treatment of flax seed. 15,141. June 4.
 Schoonderwaldt. Preparation of substitutes for linseed oil. 14,358. May 26.
 Vakil. Refining oils and fats. 14,623. May 28.

COMPLETE SPECIFICATIONS ACCEPTED.

4366 (1919). Calvert. Treatment of oils, fats, etc. (143,321.) June 2.
 25,528 (1919). Bloxam (Arbini). Neutralising oils and fats. (144,176.) June 16.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Bloxam (Act.-Ges. f. Anilinfabr.). Manufacture of resinous substances. 15,774. June 10.
 Scholz and Tiedemann. Working up scrap linoleum into new linoleum. 14,693. May 29. (Ger., 24.1.20.)
 Schoonderwaldt. 14,358. See XII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATIONS ACCEPTED.

4551 (1919). Wade (Goodyear Tire and Rubber Co.). Manufacture of rubber compounds. (143,610.) June 9.
 18,906 (1919). Burney (Westwood). Method of coagulating latex. (144,133.) June 16.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Badische Anilin u. Sodafabr. Manufacture of readily soluble tanning extracts or agents. 15,456 and 15,609. June 8 and 9. (Ger., 29.1.14 and 19.12.13.)
 Elektro-Osmose A.-G. Tanning or impregnating materials. 14,626 and 14,704. May 28 and 29. (Ger., 30.11.18 and 9.7.19.)

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Badische Anilin u. Sodafabr. Transforming ammonia into a salt for use as a fertiliser. 15,458. June 8. (Ger., 10.7.15.)
 Nitrum A.-G., and Schellenberg. Production of a solid neutral fertiliser containing nitrogen and phosphorus. 15,708. June 10. (Switz., 28.6.19.)

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Rambaud. Evaporating and concentrating apparatus for syrups etc. 15,019. June 2. (Fr., 10.6.19.)

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Clayton and Wissler. Brewing. 15,110. June 3.
 Klein. Making vinegar. 15,685-6. June 10. (U.S., 12.1.16.)
 Mapleton. Manufacture of non-alcoholic beer. 14,654. May 29.

COMPLETE SPECIFICATIONS ACCEPTED.

11,294 (1917). Geere and Geere. See XIX.
 13,338 (1919). Rogers and Bedford. Manufacture of alcohol. (144,079.) June 16.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Carpmael (Bayer u. Co.). Disinfecting seed. 15,373. June 7.
 Gould (Carolene Co.). Food products. 14,942. June 2.
 Imperial Trust, and Kidd. Preserving fruits, vegetables, etc. 15,976. June 12.
 Krizek. Apparatus for securing alcohol from baking bread. 15,757. June 10.
 Sgalitzer. Manufacture of food preparation from fresh blood. 14,624. May 28. (Ger., 15.1.16.)
 Shimizu. Manufacture of tea essence. 15,114. June 3.

COMPLETE SPECIFICATIONS ACCEPTED.

11,294 (1917). Geere and Geere. Manufacture of foods or stimulants for promoting growth of yeast. (143,938.) June 16.
 7236 (1919). Peyton and Ferguson. Preserving meat, fish, etc. (143,669.) June 9.
 10,489 (1919). Ames. Apparatus for aerating sewage etc. (143,369.) June 2.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

British Dyestuffs Corp., and Green. Manufacture of chlorides and anhydrides of organic acids. 15,103. June 3.
 British Dyestuffs Corp., and Green. Manufacture of symmetrical alkylated metaphenylenediamines. 15,864. June 11.
 Chem. Fabr. Griesheim-Elektron. Manufacture of acetaldehyde from acetylene. 14,516. May 27. (Ger., 10.8.16.)
 Du Pont de Nemours and Co. Producing tetra-substituted ureas. 15,621. June 9. (U.S. 11.9.18.)
 Soc. Chim. Usines du Rhône. Preparation of dialkylaminoethyl derivatives of theobromine. 14,465. May 27. (Fr., 1.3.20.)
 Soc. Chim. Usines du Rhône. Preparation of twice-substituted 2,4-diketo-tetrahydro-oxazols. 15,280. June 5. (Ger., 16.2.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

4018 (1919). Soc. des Aciéries et Forges de Firminy. Producing acetic acid from paraldehyde. (124,195.) June 2.
 6094 (1919). Mailhe. Production of methyl derivatives of alklamino compounds. (124,219.) June 9.
 13,293 (1919). Thompson (Poulenc Frères, Senderens, and Aboulenc). Production of benzoic acid. (143,392.) June 2.
 20,572 (1919). Soc. des Aciéries et Forges de Firminy. Manufacture of ethyl acetate from paraldehyde. (131,600.) June 9.
 443 (1920). Weiss. Manufacture of oxyaldehydes and their ethers. (139,153.) June 2.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Bloch and Renwick. Photographic materials and processes. 14,398. May 26.
 Klein. Producing photographic negatives for colour printing, colour photography, etc. 15,226. June 4.

XXIII.—ANALYSIS.

APPLICATION.

Svenska Aktiebolaget Mono. Analysing gas-mixtures. 14,621. May 28. (Sweden, 28.5.19.)

I.—GENERAL; PLANT; MACHINERY.

Volatile substances; Manipulation of —. W. A. Stock, E. Kuss, and K. Somieski. Ber., 1920, 53, 751—758.

PRECAUTIONS to be taken and special devices found useful in the manipulation of volatile substances in the determination of vapour pressure, fractional distillation, etc., are described. Liquid propylene is a very suitable substance for cooling baths at temperatures in the neighbourhood of liquid air, since it remains highly mobile at this temperature and has a very low melting point. For extremely low temperatures, instead of a cooling bath, a massive aluminium block may be used, in which four holes have been drilled; one of these serves for the introduction of liquid air and is shielded from the remainder by a suitable vulcanite screen; the other holes serve for the introduction of thermometers, experimental vessels, etc. The block itself may be insulated by being suspended in a Dewar vessel. (Cf. J.C.S., July.)—H. W.

Aluminium vessels; Method of removing "scale" from —. J. Grossfeld. Chem.-Zeit., 1920, 44, 402.

SCALE deposited on aluminium vessels, such as kitchen utensils, etc., may be removed by strongly heating the aluminium below its melting point, followed by treatment with water, by which means the deposit is softened and can be readily brushed off. The metal does not become brittle or in any way deleteriously affected. The decomposition of the chalky deposit below its dissociation temperature (835° C.) is probably brought about by the presence of small quantities of organic matter, and may also be assisted by the action of traces of magnesium compounds.—W. J. W.

PATENTS.

Air, gas, or vapours; Apparatus for subjecting — to the action of liquid in the form of spray. C. H. Fowler. E.P. 143,291, 14.2.19.

TWO or more horizontal shafts revolve at high speed within a casing and are each provided with a number of thin discs spaced apart by collars; the sets of discs may or may not interleave, but in any event the discs on one shaft come opposite to the spaces between the discs on the neighbouring shaft. Washing liquid is supplied to the spaces between the discs by jets, and is also picked up by the discs from a sump, the amount of liquid supplied by the jets being only sufficient to carry off (through an overflow) the material washed out of the gas, which passes generally in an axial direction through the apparatus, but is guided by baffles so that it must pass through the spray. (Cf. E.P. 22,282/02, 27,391/07, and 17,696/10; J., 1903, 1121; 1908, 1196; and 1911, 942.)—B. M. V.

Furnaces [; Continuous annealing —]. T. Teisen. E.P. 142,710, 16.7.19.

IN a furnace consisting of a long chamber through which the objects and the heating gases pass in the same direction, the waste gases are drawn off at intervals along the length of the furnace through damper-controlled passages leading to a collecting chamber under the furnace and thence to an outlet or outlets. The goods are thus cooled gradually and the rate of cooling may be increased by cold air admitted at the exit end of the furnace. The combustible is preferably provided by a gas producer situated under the heating end of the furnace, and the air for combustion may be preheated by passing it through passages built in the walls of the furnace. —B. M. V.

Furnace. H. B. Kinnear and A. J. Townsend. U.S.P. 1,339,564, 11.5.20. Appl., 12.5.19.

THE goods are pushed upwards through one or more vertical tubes arranged within a heating chamber. —B. M. V.

Kiln. K. Himrod, Assr. to P. W. McKay. U.S.P. 1,339,705, 11.5.20. Appl., 30.8.16.

IS a kiln with inlet openings communicating with a flue and having an adjacent burner also in communication with the flue, a conduit is arranged between the burner and kiln through which a fluid may be delivered to the flue. Means are provided for generating and superheating steam, for mixing it and the fluid with the combustion products from the burner, and for directing this mixture into the kiln.—W. J. W.

Kiln. J. N. Silva. U.S.P. 1,340,633, 18.5.20. Appl., 28.2.19.

AN intermittent kiln comprises several round down-draught kilns, a feeding flue and an exhaust flue extending past them all, a manifold with its ends connected with the flues and its body encircling each kiln and communicating with the interior thereof, and a single flue common to the kilns and communicating with the central well of each kiln and with the exhaust flue. A branch exhaust flue draws the gases from the main flue and discharges them into the chimney and a pressure fan blows air into the feed flue.—A. B. S.

Kiln; Annular —. G. Zehner. G.P. 315,773, 23.2.16.

AN annular kiln has its crown supported by a series of upright pillars so arranged that there are alternate openings on opposite sides of the combustion channel which may be employed to convey the gases through the kiln in a zig-zag course. The kiln can thus be used alternately as an annular kiln and as a zig-zag oven, or it can be used partly as the one and partly as the other.—L. A. C.

Tunnel kiln. F. K. Meiser. G.P. 319,440, 28.9.18.

THE kiln is suitable for chemical reactions, for ignitions in different gas atmospheres, and for the recovery of vapours and gases from the material under treatment. The material is supported in the kiln in tanks, crucibles, or other vessels connected in series by detachable, movable pipes. The pipes of the individual vessels may dip in a liquid seal of a longitudinal conduit in which movable valves may be arranged so that a gas can be supplied to a definite part of the apparatus.—A. R. P.

Treating air or gases with liquids or vice versa; Apparatus for —. W. J. Bulgin, E. A. Hall, and G. Searle. E.P. 142,941, 17.2. and 29.7.19.

IN a rotary scrubber in which the rotating part dips into liquor within a cylindrical container, the working surface which retains a film of liquor consists of twisted flat strip which may be secured to the rotor in several ways, such as winding involutely between radial arms, or in several layers or zig-zag fashion on flat strip provided with projections to hold the twisted strip in place. Baffles of conical or *vena contracta* shape may be provided to ensure the passage of the air or gas through the effective portions of the rotor.—B. M. V.

Atomising more or less viscous materials; Method and means for —. A. Sonstbagen and E. H. Harberd. E.P. 143,289, 11.2.19.

THE material is spread in a thin layer on a smooth roller or belt moving comparatively slowly, and is removed therefrom by bristles or spikes projecting from another roller or belt which moves much faster, so that the material is thrown off from the projec-

tions by centrifugal force in the form of drops. The bristles or spikes project into the layer of liquid on the first roller or belt, but do not quite touch the roller itself, and just before they enter the liquid they may be bent back by a suitable obstruction and then suddenly released.—B. M. V.

Absorbing gases; Methods and means for — and their application to vacuum flasks for storing low-temperature liquids. H. C. Jenkins. E.P. 143,365, 15.4.19.

GRANULATED or powdered coal is used instead of charcoal for improving and maintaining the vacuum in vacuum flasks.

Condenser for distilling apparatus. J. H. Zaeckel. E.P. 143,428, 16.7.19.

THE vapour passes into a pipe, inclined upwards, from which vertical branches extend downwards into open vessels for the collection of distillates of various degrees of volatility. A number of similar pipe sections may be used, with the lower ends of the inclined pipes alternately on opposite sides.

—B. M. V.

Distillation of liquids; Apparatus and process for the continuous —. F. I. Gibson. U.S.P. 1,324,417, 9.12.19. Appl., 2.8.18.

A STILL is divided into several compartments with restricted communicating passages for the liquor, but all opening to one common vapour space. The liquid is fed continuously to the first compartment and the residue withdrawn from the last compartment.—B. M. V.

Evaporating apparatus. K. L. E. Thunholm. U.S.P. 1,324,417, 9.12.19. Appl., 2.8.18.

LIQUID to be evaporated is fed into the upper end of a vertical cylinder, divided by double horizontal partitions into a number of superposed chambers. The partitions are provided with central pipes, which pass through the upper and lower plates and through which a vertical shaft passes, having arms, carrying rakes which are rotated in each chamber. Passages are also provided through which the vapour passes upward to the outlet at the top and other sealed passages through which the liquid flows down from chamber to chamber to the concentrated liquor discharge at the bottom. Evaporation is effected by steam which passes through the double partitions, each of which is provided with an inlet and an exhaust connexion.—W. H. C.

Electrical precipitators; Method of regulating the velocity of fumes passing through —. W. W. Strong, Assr. to Research Corp. U.S.P. (A) 1,337,488 and (B) 1,337,489, 20.4.20. Appl., 25.9.17.

(A) DEVICES controlled automatically are placed in the different pipes of an electrical precipitator of the multiple pipe treater type in order to equalise the flow of gas therein. (B) A treater chamber has a discharge electrode extending through it and is provided with means for constricting the flow of gas adjacent to the electrode and also for preventing a disruptive discharge from the electrode to the constricting means at voltages below the normal critical one.—B. N.

Electrodes; Removing deposits from — [in electrical precipitators]. A. F. Meston, Assr. to Research Corp. U.S.P. 1,339,471, 11.5.20. Appl., 23.10.17.

MEANS are provided for striking the discharge electrodes of an electrical precipitator intermediate of the ends to cause vibration.—B. N.

[Electrically] separating suspended particles from gases. W. A. Schmidt, Assr. to International Precipitation Co. U.S.P. 1,339,480, 11.5.20. Appl., 27.8.17.

A CLEAN electrode surface, for receiving the precipitated material, is maintained by distributing a liquid in a film over a porous surface constituting the receiving electrode.—B. N.

Gases; Apparatus for the electrical precipitation of dust from —. Siemens - Schuckertwerke G.m.b.H. G.P. 315,931, 29.6.18.

DUST etc. is removed from blast-furnace gas or the like by passing the gas through a number of electrodes consisting of frames in which are mounted a series of pivoted plates arranged, either horizontally or vertically, in a manner similar to that of the laths of a venetian blind. The plates in alternate frames serve as precipitation electrodes and as high-potential electrodes respectively, and are inclined in opposite directions, so that repeated changes of direction are imparted to the gas.—L. A. C.

Dryer. W. B. Hutchinson, Assr. to A. Blackburne. U.S.P. 1,338,731, 4.5.20. Appl., 23.5.19.

In a rotary dryer with screw feed the blades are perforated to enable air to be blown through the screw and dryer in a contrary direction to the feed.—W. J. W.

Drying materials; Process for —. H. B. Lowden. U.S.P. 1,339,771, 11.5.20. Appl., 22.10.17.

THE material is caused to pass over a heated hearth by repeatedly cleaving it in a substantially vertical direction and at the same time imparting to it a slight forward motion.—W. H. C.

Dehydration of moist materials; Apparatus for [electro-osmotic] —. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 316,443, 4.9.17.

In the apparatus previously described (G.P. 314,338; J., 1920, 53 A), the movable walls rest at their lower end in a bed provided with a run-off conduit for the separated liquid. A channel from one side of each wall, or channels from both sides, pass through the lower end of the wall and open into the discharge conduit.—W. J. W.

Pulveriser; Rotary —. E. Cortese, M. Crespi, and A. Squassi. U.S.P. 1,339,499, 11.5.20. Appl., 29.1.20.

A PULVERISING chamber provided with beater bars attached to wheels mounted on a rotating shaft and also with stationary pulverising means, has a blower, mounted independently on the shaft, which blows the powder and granular material from the beaters against a grid fixed over an opening in the casing.—W. H. C.

Refrigerating apparatus. R. B. Henderson and R. E. James. U.S.P. 1,339,622, 11.5.20. Appl., 13.5.18.

A GENERATING chamber, provided with means by which it can be heated and cooled, is connected by a gas passage and a liquid return pipe with a cooled dehydrating chamber, supported on the generator. The dehydrating chamber is connected with a cooled condenser by a pipe provided with an automatic and also with a manually operated valve. The refrigerant passes at intervals from the condenser to a refrigerating coil by a valved pipe and thence up a vertical pipe back to the generating chamber.—W. H. C.

Photochemical apparatus. W. O. Snelling. U.S.P. 1,339,675, 11.5.20. Appl., 1.3.17.

THE reacting fluids are caused to pass through a series of transparent vessels, each of which has a source of light opposite to it, the distance between

the source of light and the reaction vessel being decreased progressively in the direction of flow of the fluids.—W. H. C.

Separating device; Settling basin —. *Upward-current separating process and device. Slime-pulp thickener.* C. Allen. U.S.P. (a) 1,339,682, (b) 1,339,683, and (c) 1,339,684, 11.5.20. Appl. (a) (b) 3.7.17, (c) 5.10.18.

(A) To prevent irregular discharge at the outlet of a de-watering settler, a diaphragm or other obstruction is placed over the outlet in such a way as to leave an attenuated passage for the settling material for a considerable distance above the orifice. (B) The overflow lip of a settling device is adjustable as to circumferential length in order to vary the velocity of overflow. (C) The size of the outlet orifice of a pulp thickener is varied by means controlled by the level of a fluid of fixed density (e.g., clear water), which is in hydrostatic balance with the settling pulp. The clear fluid chamber is preferably arranged within the settler and provided with an inverted conical baffle underneath.

—B. M. V.

Catalysts; Manufacture of —. J. Boyce, Assr. to The American Cotton Oil Co. U.S.P. 1,339,686, 11.5.20. Appl., 2.6.13.

GRANULATED inert material is mixed with an adherent material so that the individual grains are coated. The coating contains a compound of the catalytic metal, and the coated material is treated to convert the compound to a catalytically active material, e.g., "nickel black."—B. M. V.

Fractionating compound substances containing ingredients of closely-related solubility. A. Seidenberg. U.S.P. 1,340,186, 18.5.20. Appl., 10.8.18.

A NUMBER of solvents are chosen such that the most volatile solvent dissolves the least soluble constituent most easily and the least volatile solvent dissolves the most soluble constituent most easily. The compound substance is dissolved in the mixed solvent, which is then gradually volatilised, so as to precipitate the constituents in the reverse order of their solubility.—B. M. V.

Heat exchanger. Method of exchanging heat. H. D. Hildebrand. U.S.P. (a) 1,340,266 and (b) 1,340,267, 18.5.20. Appl., 2.1.17 and 21.4.19.

TWO fluids, between which interchange of heat is desired to take place, are passed through elements consisting of a number of nested pipe sections, alternate sections of one element being connected with alternate sections of an adjacent element, so that the fluid to be heated flows through progressively smaller annular passages and the fluid to be cooled through progressively larger passages.

—B. M. V.

Crystallisation of salts; Utilisation of the heat liberated during the — from hot liquors. E. Roser. G.P. (a) 316,492, 1.3.18, and (b) 316,493, 20.3.18.

(A) HOT vapours liberated from liquors during crystallisation are conducted into an apparatus in which they are utilised for assisting the solution of the raw material. (B) Additional heating of the raw material and solvent may be effected by means of steam or hot gases in a second apparatus, from which any residual hot vapours are caused to pass into the first apparatus.—W. J. W.

Salt solutions; Apparatus for cooling hot —. Maschinenbau-A.-G. Balcke. G.P. 319,439, 26.6.18.

THE apparatus consists of a series of troughs provided with rotating cooling discs, which are fitted

with paddles, by the help of which the salt crystals and the solution are moved through the troughs.

—A. R. P.

Filtering gaseous substances; Apparatus and process for —. L. B. Fiechter. G.P. 317,254, 31.3.18. Conv., 2.11.17.

THE apparatus comprises a rotating flat screen over which the granular filtering material, e.g., sand, is distributed, and from which it is removed continuously or at intervals, elevated to a purification plant, and then, by means of a vertical shaft with guard rail, returned to the screen in a layer of the requisite thickness.—W. J. W.

Pneumatic separators. Williams Patent Crusher and Pulverizer Co., Assees. of A. J. Roberts. E.P. 139,749, 6.8.19. Conv., 1.3.19.

Separators for grading crushed rock and other materials. T. J. Sturtevant. E.P. 142,989, 9.4.19.

Purification of [used lubricating] oil and other liquids; Apparatus for —. King's Patent Agency, Ltd. From D. Stone. E.P. 142,703, 2.7.19.

Evaporators. K. L. E. Thunholm. E.P. 118,635, 23.8.18. Conv., 23.8.17.

Distillation. G.P. 315,012. See III.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Gases of combustion of coal; Approximate determination of the amount of —. F. Castek. Feuerungstech., 1920, 8, 133—136.

IT is shown that the amount of gas produced by the combustion of coal can be calculated from the carbon content or the calorific value of the coal. Using the theoretical quantity of air, the volume of dry combustion gases (G) in cub.m. from one kg. of coal is one-tenth of the percentage of carbon in the coal (C). If v times the theoretical quantity of air is used, $G=0.1Cr$ and $v=18.65/x$, x being the percentage of CO_2 in the gases of combustion. If the calorific value of the coal is B, the carbon content is $B/97\%$.—A. G.

"Double gas" and its use in gas works. H. Strache. J. Gasbeleucht., 1920, 63, 230—235.

THE author advocates the adoption of a system of primary gasification followed by steaming, leading to the production of "double gas." This gas has a calorific value of 3330 cals. per cub.m., as compared with 5500 cals. for ordinary coal gas from the same coal. The amount of coal gas produced per 100 kg. of coal is 33 cub.m. and the amount of "double gas" 160 cub.m., the total calorific values being 425,100 cals. in the former case, assuming the coke to be used for the production of water-gas, and in the latter case 533,400 cals. The minimum calorific values of the gas and tar are given as 60.2% and 8.3% of the heat of the coal respectively. Advantages claimed for the process are:—Reduced floor-space, apparatus always ready for use, reduction in labour and low initial cost. The yield of by-products is greater than if coal- and water-gas are produced separately and then mixed. The tar (sp. gr. 1.012) contains: water, 33.7%, pitch, 18.9; paraffin, 1.5; light oils, 19.4; heavy oils, 24.3; ammonia, 0.91; insol. in benzol, 1.65; and ash, 0.28%.—A. G.

Gas producer plants operating with recovery of low-temperature tar and ammonium sulphate; Economics of —. E. Roser. Stahl u. Eisen, 1920, 40, 349—357, 387—395.

On the basis of tests with coal, lignite briquettes, and mixtures of coal and briquettes carried out on an installation of 15 Thyssen rotary-grate gas producers, the advantages of the gasification of fuel in by-product gas producers are set out in detail for varying conditions as to prices of raw materials and of products.

Gas producer plants operating with recovery of low-temperature tar and ammonium sulphate; Economics of —. Stahl u. Eisen, 1920, 40, 532—541, 610—621, 651—655, 685—689.

A FULL account of a discussion on two communications by Roser (preceding abstract) and Klingenberg (Stahl u. Eisen, 1918, 38, 2—11, 32—36, 46—51, 65—68).

Oxide [gas] purification; Practice and control of —. G. Weyman. Gas J., 1920, 150, 489—490.

THERE are three possible ways of removing hydrogen sulphide from coal gas by oxide purification. The first method is to form ferric sulphide, this being subsequently oxidised to free sulphur. The process is limited to the use of true bog ore or an artificial oxide consisting of precipitated hydroxide, and the presence of an alkali is necessary to neutralise any acid that may be formed. Ammonia is the best alkali to use as it can be distributed most efficiently. The development of heat must be restricted owing to increase in acidity with rise of temperature. For this purpose, as much water should be used as the oxide will carry without being wet. In the second process, ferrous sulphide is the intermediate product, and since acid conditions are favourable higher temperatures may be employed. Natural ores and burnt oxide can be used with good results, but the process should not be employed if the purifying area is below 0.5 sq. ft. per 1000 cub. ft. per 24 hrs. The oxide should be worked as dry as possible, and 50% of sulphur should be obtained without more than one removal. In the third process, which has not yet been applied to coal gas purifiers, most of the sulphur is oxidised direct to sulphuric acid and ferrous sulphate is produced which may be removed in solution. The temperatures used must be higher than usual and the conditions must be acid. Success in any of these methods depends on the material used, the plant available, and the temperature which can be maintained. Improved results have been attained by the passage into the purifiers of preheated air, and steam gives better results than water for moistening the oxide. The author advocates careful temperature control, determination of the ammonia and tar fog in the inlet gas and of the hydrogen sulphide at the outlet of the first two boxes. The liquid drainage should be examined regularly and the spent oxide tested for ammonia.—A. G.

Petroleum; Constitution of organic nitrogen bases of Californian —. C. F. Mabery and L. G. Wessen. J. Amer. Chem. Soc., 1920, 42, 1014—1020.

A RE-EXAMINATION of the basic constituents of Californian petroleum (J., 1900, 505) has shown them to consist mainly of alkylated quinelines (or isoquinolines). All the fractions boiling over intervals of 2°—4° covering a range of 130°—283° C. at 50—90 mm. gave pyridinepentacarboxylic acid and a methylpyridinetetracarboxylic acid on oxidation with potassium permanganate, and therefore contain at least three alkyl groups, of which the relatively simple nature is shown by the absence of

propionic or higher fatty acid from the oxidation products. 3-Methylquinoline was obtained by distilling with lime the product obtained by oxidising one fraction with chromic acid, and a medium fraction yielded a phthalone derivative by condensation with phthalic anhydride. (Cf. J.C.S., July.)—J. K.

Ammonium sulphate. Shewring. See VII.

Gas analysis. Ott. See XXIII.

PATENTS.

Coal or other mineral washing apparatus. A. France. E.P. 142,729, 15.9.19.

THE washing troughs are arranged in batteries in cascade form; the dense material discharged from the separators of one trough is subjected to another washing in a trough below, this process being repeated until the necessary grade is obtained.—A. G.

Coal; Process for treating —. J. N. Wingett, Assr. to W. A. Haggott. U.S.P. 1,337,496, 20.4.20. Appl., 3.5.15.

COAL is hardened, preparatory to shipment or storage, by heating it during its passage through a closed chamber, sufficiently to drive off certain volatile constituents adjacent to the surface only. The heavier oils are caused to move to the surface and dried, giving the coal a hard exterior, protecting it against exposure to the atmosphere, and preventing the formation of dust and slack.—B. N.

Coke; Manufacture of hard — from gassy coals. F. Saefel. G.P. 317,120, 9.5.18.

THE charge for coking consists of a mixture of the raw coal and coal which has been partly de-gasified.—W. J. W.

Coke oven with vertical heating flues. C. Otto u. Co. G.P. 317,962, 22.8.16.

A NUMBER of flues are built in immediate contact with the furnace side of the oven wall and others are built within the wall and communicate above with one another. Combustion takes place from below upwards in a number of narrow pipes, which communicate above with the heating flues by means of separate channels built into the upper portion of the oven wall, or by one continuous channel, in such manner that the products of combustion pass downwards through the heating flues with eddying motion.—J. S. G. T.

Chamber oven for gas production. H. Bröcker. G.P. 315,099, 23.3.18. Addition to 314,118 (J., 1920, 5 A).

THE oven comprises an upper and lower chamber separated by means of an inclined partition extending part of the way across the oven, and a slide which may be withdrawn when desired to afford communication between the chambers. The upper chamber serves as a carbonising chamber and can be put in communication with or cut off from the hydraulic main as desired. The lower chamber functions as a gas producer and is fed with hot coke from the upper chamber by withdrawing the slide.—J. S. G. T.

Coal; Gasification of — and obtaining by-products therefrom. C. H. Smith. E.P. 123,738, 17.2.19. Conv., 16.2.18.

CAKING coal is subjected to a preliminary distillation at temperatures below that at which substantial quantities of ammonia pass off, being agitated continuously and the gas and tar withdrawn until the coal loses its caking properties. The residue is subsequently treated in a by-product gas producer, to obtain producer gas or water gas, with recovery of ammonia. The distillation takes place at 800°—950° F. (about 430°—510° C.).—A. G.

Fuels; Gasifying of solid and liquid —. N. H. Freeman. E.P. 142,945, 19.2.19.

STEAM is heated to a temperature exceeding the ignition point of the fuel to be gasified and is applied to the fuel in this highly heated condition in a chamber in which the temperature is maintained at or above the ignition point of the fuel. In one type of apparatus oil is fed into a stream of steam concentrically through a jet, whilst if pulverised coal is used it is discharged through a hopper into the steam chamber.—A. G.

Carbon-hydrogen gas; Process of producing —. T. O'Connell. U.S.P. 1,310,495, 18.5.20. Appl., 10.9.19.

THE first layer of ignited coal in a gas producer is subjected successively to an air blast and a steam blow, both of equal length and directed from beneath the coal, to another air blast and steam blow similar to the former, to an air blast, to a steam blow directed from the top and lasting $\frac{1}{2}$ of the air blast, to a steam blow from the bottom lasting $\frac{1}{2}$ of the air blast, to a succession of two periods of operation, each period comprising an air blast and a steam up-blow of equal length, followed by three operations, each consisting of an air blast, a steam down-blow of $\frac{1}{2}$ of the blast period, and a steam up-blow of $\frac{1}{2}$ of the blast period. Coal is deposited in the centre of the fire after the last steam up-blow, and this is followed by two periods of air blast and steam up-blows of equal length and the process continued in the above described order, including the coaling, until the last coaling operation before cleaning of the fire has taken place and has been followed by a double air blast and steam up-blow, the coal thus prepared being subjected up to the point of cleaning to a series of operations consisting of air blasts, steam down-blows of $\frac{1}{2}$ of the air blasts, and steam up-blows of $\frac{1}{2}$ of the air blast periods.—A. G.

Gas-producer with annular charge. J. Schulte. G.P. 316,412, 3.1.17.

THE charge is contained within the producer in a tall annular chamber. By means of helical baffles the gas is caused to take a tortuous path in the spaces surrounded by and surrounding the annular chamber and is drawn off from the respective regions by separate pipes each provided with a separate cock and leading into a common pipe. Partitions are provided in the spaces within and without the annulus to force the gas into more intimate contact with the walls of the producer chamber.—J. S. G. T.

Gas producer. Maschinenfabrik Augsburg-Nürnberg A.-G. G.P. 317,220, 18.3.17.

THE stepped grate of the producer, which is relatively long in horizontal cross-section, is carried on a horizontal pipe which is turned about its axis alternately in opposite direction. The fuel is thereby broken up by being pressed alternately against one or other of the side walls of the producer.—J. S. G. T.

Ethylene; Compression, storage, etc. of —. A. A. Backhaus, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,339,431, 11.5.20. Appl., 6.6.19.

A CYLINDER suitable for commercial transportation has its interior free from absorbent filler and solvent and contains ethylene compressed to a high pressure, the amount of ethylene being more than $1\frac{1}{2}$ times the amount of hydrogen in a cylinder of the same size under the same pressure.—A. G.

Blast-furnace gas; Cleaning of —. N. K. Turnbull. E.P. 142,938, 15.2.19.

THE gas is filtered and is then purified, the cooled gas being passed in counter-current to the incoming

crude hot gas, thus being reheated and being in a more suitable condition for combustion in stoves, boilers, and the like or for use in gas engines.

—A. G.

Gases; Method and apparatus for cleaning —. F. R. McGee. U.S.P. 1,338,143, 27.4.20. Appl., 13.5.18.

THE cleaner comprises a gas-distributing chamber, a collecting chamber connected with the distributing chamber by a series of conduits and an impurity-receiving chamber provided with a gas outlet. The conduits have annular outlets opening into the impurity-receiving chamber and means in each conduit for imparting a whirling motion to the gases passed through them.—A. G.

Gasoline; Manufacture of —. J. W. Trotter. U.S.P. 1,339,727, 11.5.20. Appl., 14.11.18.

PARTLY refined hydrocarbon oil is converted into gasoline by spraying it through a "submerged catalytic spray" into a bath of oil under a pressure of not less than 75 lb., in the presence of superheated steam and at a cracking temperature.—C. A. M.

PATENTS.

Asphalt rock, bituminous slate, etc.; Furnaces for the distillation of —. A. la Porta and R. do Bartolomeis. E.P. 142,511, 3.2.19.

A VERTICAL shaft furnace comprises a lower zone for the spent material and a middle combustion zone wherein part of the combustible matter of the rock etc. is burnt to provide the necessary heat for the distillation of the remainder in the third, or upper, zone, which is wider than the combustion zone but not so wide as the spent material zone.—A. G.

Decolorising carbon; Preparation of an active —. Zellstoff-fabrik Waldhof. G.P. 309,155, 22.6.17.

A DECOLORISING carbon with a greater efficiency

than wood or animal charcoal is obtained by carbonising the residues derived from the hydrolysis of cellulose or cellulosic materials.—W. J. W.

Gases from anthracite and petroleum coke; Treatment of — [in manufacture of carbon electrodes]. F. K. Meiser. G.P. 317,179, 19.6.17.

IN the manufacture of electrodes from anthracite and petroleum coke the gaseous products are mechanically freed from alkaline vapours at a temperature sufficiently high to prevent condensation of the tar. They may then be employed for heating the furnace without risk of attacking the firebrick.—W. J. W.

Electric discharge tubes and the like; Methods of and apparatus for automatically removing gases from —. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 141,913, 30.4.19.

THE operation of an incandescence cathode vacuum device is controlled during evacuation by means of a high-potential transformer which supplies operating current from its secondary to the device, with a resistance in the primary circuit. A low-potential transformer for heating the cathode is supplied with current from the primary circuit of the high-potential transformer, and the gases disengaged during the action are removed from the container.—B. N.

Incandescence bodies; Manufacture of —. W. Heseler, G.m.b.H. G.P. 319,613, 28.7.18.

INCANDESCENCE bodies in tubular or massive form are obtained by pouring artificial silk or like material into appropriate moulds. The incandescence material may be admixed with the silk or incorporated subsequently to casting.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Chlorination of benzene; Kinetics of the —. F. Bourion. Comptes rend., 1920, 170, 1319—1321.

IN the chlorination of industrial benzene in the presence of iron as a catalyst the yield of monochlorobenzene increases with the velocity of chlorination, but decreases slightly with rise in temperature. For a given concentration and a given time the molecular proportion of benzene converted into monochlorobenzene is 8.5 times greater than the molecular proportion of chlorobenzene converted into *p*-dichlorobenzene.—W. G.

Benzene separated from industrial chlorobenzenes; Impurities in —. F. Bourion. Comptes rend., 1920, 170, 1181—1184.

THE chief impurity present in the benzene obtained by the process of enrichment from industrial chlorobenzene (J., 1920, 425 A), is chloroform, minor impurities being hexane and heptane.—W. G.

p-Phenylenediamine and aniline; Preparation of — from the corresponding chlorobenzenes. A. J. Quick. J. Amer. Chem. Soc., 1920, 42, 1033—1042.

THE catalytic influence of copper salts on the reaction between ammonia and chlorobenzene (G.P. 204,951; see E.P. 3396 of 1908; J., 1908, 1147) or *p*-dichlorobenzene (G.P. 202,170; J., 1908, 1147) is not connected with the formation of copper ammonium compounds, since nickel, cobalt, and zinc salts, which form similar compounds, have no influence. Cuprous salts are more effective than cupric salts, which probably only become effective when reduced; and water cannot be replaced by alcohol as a solvent in the reaction. The reaction with dichlorobenzene is best carried out above 200° C.; with 5—6% solution of ammonia the reaction is very

incomplete, and an amorphous red product is also produced. Addition of iron filings or activated charcoal to the cuprous salt improves the appearance of the final product, but with concentrated solutions of ammonia they, particularly the former, tend to retard the reaction. The action of ammonia on chlorobenzene under the conditions prescribed gave only a 39% yield, as against 80% claimed by the patent. Increase in the concentration of ammonia beyond 14% or in working temperature beyond 200° C. does not improve the yield, although the latter is necessary for complete decomposition of the chlorobenzene. Cuprous iodide has no catalytic value for this reaction. Diphenylamine could not be obtained from bromobenzene and aniline in presence of cuprous iodide under the conditions prescribed in G.P. 187,870 (F.P. 374,385; J., 1907, 756).—J. K.

PATENTS.

Dehydration of liquid mixtures [aqueous phenol] by distillation. K. Kubierschky. G.P. 315,012, 9.5.18.

THE method is applicable to mixtures of liquids which are not completely soluble in water, and in the early stages of distillation give distillates which separate into two layers—one containing much water, the other little water. Two distilling columns, with draw-off pipes for liquid on their lower parts, are connected with a common condenser. The liquid mixture to be dehydrated—e.g., a mixture of water and phenol—is supplied to one of the columns and is rectified, water-free phenol being run off below and water along with a certain amount of phenol passing to the condenser, where the distillate condenses and separates into two layers, a lower containing little phenol and an upper rich in phenol; these are discharged respectively to one or other of the columns and the process continued until finally pure phenol is run off from one and water from the other, keeping pace with the supply of the mixture to the still.—J. S. G. T.

2-Aminoanthraquinone; Process of making —. M. Fischer. Assr. to J. R. Geigy S.A. U.S.P. 1,340,603, 18.5.20. Appl., 8.3.19.

SEE E.P. 127,223 of 1919; J., 1919, 529 A.

Sublimation. E.P. 142,902. See XX.

IV.—COLOURING MATTERS AND DYES.

1-Hydroxy-4-chloroanthraquinone. F. Ullmann and A. Conzetti. Ber., 1920, 53, 826—837.

THE preparation of various derivatives of 1-hydroxy-4-chloroanthraquinone, m.p. 192° C., obtained from 1-hydroxyanthraquinone by the action of sulphuryl chloride in the presence of nitrobenzene at 100° C. is described. N-1-Hydroxyanthraquinonyl-4-anthranilic acid, bluish-violet shining needles, m.p. 272° C. (decomp.) is obtained by boiling a solution of 1-hydroxy-4-chloroanthraquinone and anthranilic acid in amyl alcohol with anhydrous potassium acetate in the presence of copper acetate and copper powder; it is converted by treatment with acetic anhydride and pyridine and subsequent action of *p*-toluenesulphonic chloride on the acetyl derivative thus produced into 4-hydroxyanthraquinone-2.1-acridone, shining blue leaflets, m.p. 321° C., which gives blue shades on cotton from a wine-red vat.—H. W.

Glyoxaline nucleus; Some properties of the —. [Glyoxaline-azo dyestuffs.] F. L. Pyman. J. Soc. Dyers and Col., 1920, 36, 107—112.

A GENERAL survey of the simple glyoxaline derivatives is given. Arylazoglyoxalines dye wool yellow to brown shades; the colour produced by

2-benzeneazoglyoxaline is readily removed by dilute acids, but that obtained by means of 2-*p*-sulphobenzeneazoglyoxaline-4,5-dicarboxylic acid is comparatively fast to washing and to acids. Some of the derivatives of glyoxaline should be suitable as dyestuffs similarly to those of the isomeric compound pyrazole.—L. L. L.

Sulphur; Removal of — from organic compounds by means of arsenic trioxide. W. Herzog. Z. angew. Chem., 1920, 33, 140.

ORGANIC compounds, and especially thioureas and their derivatives, may be readily freed from sulphur by boiling them in an inert solvent (xylene) with arsenic trioxide beneath a reflux condenser. The method is particularly suitable for the preparation of carbodiphenylimide (for use in Sandmeyer's indigo synthesis) from symmetrical diphenylthiourea.—C. A. M.

Picric acid. Doll. See XXII.

PATENTS.

Indophenolic compounds; Manufacture of —. F. à Brassard and Crawford, and E. A. Buckle. E.P. 143,014, 3.5.19.

IN the condensation of *p*-nitrosophenol and the product of which it is desired to make the indophenolic compound it is ensured that these are always reacting in equimolecular proportions by grinding them together before effecting the reaction in presence of concentrated sulphuric acid.

—A. J. H.

Dyestuffs and process of making same. A. Angel; M. L. Angel, extrix. U.S.P. 1,340,696, 18.5.20. Appl. 16.7.18.

SEE E.P. 121,347 of 1917; J., 1919, 101 A.

Photosensitising dyes. U.S.P. 1,338,346 and 1,338,349. See XXI.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Constituents of raw —. II. E. Knecht and F. V. Fernandes. J. Soc. Dyers and Col., 1920, 36, 43—47 (Cf. J., 1911, 1007; 1919, 7 A.)

TABLES are given showing the percentage of matter extracted from Egyptian and American cotton by different solvents, the effect of heat on the extracts, and their nitrogen content. In samples of untreated and extracted cotton dyed with Methylene Blue there was no diminution in intensity after the cotton had been successively extracted with benzene, alcohol, and water; on the contrary, the colour became, if anything, brighter. An albuminoid substance has been obtained from cotton which yields a coloured lake with Methylene Blue. The amount of tannic acid absorbed by cotton diminishes as the impurities are successively removed. A table is given showing the tensile strength of extracted cotton in the conditioned state and dried at 100° C.—L. L. L.

Wool fibre; Influence of humidity upon the strength and elasticity of —. J. I. Hardy. J. Agric. Res., 1920, 19, 55—62. (Cf. J., 1918, 728 A.)

THE tensile strength of wool increases with decrease in the diameter of the fibres. The breaking strength of fine wool varies with the diameter; that of coarse wool varies with a figure between the first and second powers of the diameter. Increase of humidity to 80% causes a decrease in the tensile and breaking strengths of scoured and unscoured wool, while above 80% a slight increase occurs. The elasticity of scoured and unscoured wool increases with the humidity to 80% and decreases from 80% to the saturation point.—J. I. J.

Wool and cloth; Action of atmospheric influences on —. A. Kertesz. Färber-Zeit., 1920, 31, 1—4. A. Grass. *Ibid.*, 61—68. (Cf. A. Kertesz, J., 1919, 496 A.)

IN reply to Von Kapff (Färber-Zeit., 1919, 30 [23]; cf. J., 1908, 329), who maintains that wool is weakened by chroming and cites in support the decreased durability of certain modern chrome-dyed Army clothing, Kertesz disputes the validity of Von Kapff's measurements, and attributes the weakness of the Army clothing to conditions of manufacture. He strongly supports the observation of Reebberg (G.P. 286,310; J., 1915, 1140; cf. G.P. 303,231; J., 1920, 61 A) that chrome-dyed wool better withstands exposure to air than pure wool. Grass points out that no conclusions as to the durability of dyed wool under ordinary conditions should be drawn from the behaviour of Army clothes since they were exposed to totally abnormal conditions. The value of the experimental work of Kertesz is lessened by the facts that the conditions employed did not correspond with those of industrial methods and the duration of the chroming was not sufficiently prolonged; moreover, it was not shown that the woollen fabric used in the tests was normal.—A. J. H.

Fabrics; Resistance of — to climatic conditions and to ultra-violet rays. L. Vignon. Comptes rend., 1920, 170, 1322—1324.

FABRICS of linen and of chappe silk weighing respectively 110 g. and 100 g. per sq. m. were submitted to varying conditions of light, heat, and moisture, and their breaking strength then measured. The results indicate that the tissues of animal origin (chappe silk) are more resistant than those of vegetable origin (linen) to variations in climatic conditions and to the action of ultra-violet rays, the probable explanation being that the protein molecule is more resistant to hydrolysis than the cellulose molecule.—W. G.

Fabrics coated with solutions of cellulose esters; Dynamometric examination of —. L. Clément and C. Rivière. Chim. et Ind., 1920, 3, 440—444.

THE strength of fabrics is increased by coating with cellulose acetate, a solution of the latter in tetrachloroethane giving a slightly stronger coating than a solution in acetone or benzyl alcohol; tetrachloroethane and acetic acid have no injurious effect on the strength of linen. Oil varnish should not be applied to fabrics coated with cellulose acetate, since it diminishes the strength of the material. A coloured coating is best produced by applying to the fabric first one layer of a tinted solution of cellulose acetate and then three coats of colourless solution. The weakening effect of sunlight on coated fabrics is marked during the summer months, but may be prevented by the use of suitable pigments in the coatings.—W. P. S.

Sulphate cooking process; Control of —. W. E. B. Baker. Pulp and Paper Mag., 1920, 18, 544—545.

CONTINUOUS records of gauge pressure and temperature must be made and gas pressure curves plotted from differences between gauge and steam pressures. Specific gravity determinations should be made at regular intervals on cooled samples. Total sulphur dioxide is estimated by iodine titration, the interference of "reversible sulphur dioxide" being overcome by taking the first blue coloration as the end point. In the determination of "half-bound" sulphur dioxide by plotting the differences between results of the iodine and soda titrations an error not exceeding 0.2% SO₂ is introduced, due to acidity other than sulphurous acid. The curve for changed sulphur concentration, plotted from the differences between total sulphur and sulphur titratable by iodine, is a rising one, the rate of ascent giving an indication of the progress

of the lignone reaction. Reversible or loosely combined sulphur dioxide is estimated by treating the liquor with excess of alkali, acidifying with hydrochloric acid, and titration with iodine, the curve being a rising one and sometimes oscillatory. For lime and magnesia estimations a sample is treated in a sealed tube; the curve falls and again rises, the minimum point being of importance.

—W. J. W.

Lignin and reactions of lignin. P. Klason. Ber., 1920, 53, 706—711.

The naphthylamine ligninsulphonate described previously (J., 1919, 570A) has been investigated further. Its formation is considered to indicate the presence of the group $R.CH:CH.CHO$ in lignin. It is formed in greater quantity from old than from fresh sulphite liquors, and it would appear that the group $CHR:CH.CH_2OH$ is present in the latter, and that the aldehyde, in part, at any rate, is gradually formed in them by atmospheric oxidation. It is concluded that coniferyl aldehyde and coniferyl alcohol are the principal constituent groups at any rate of the lignin of conifers.—H. W.

Lignin in cellulosic materials; Direct estimation of —. E. Becker. Papierfabr., 1919, 17, 1325—1327. Chem.-Zentr., 1920, 91, II., 347.

ONE gram of the finely divided material is mixed with 10—20 c.c. of 72% sulphuric acid by means of a glass rod. When the mass becomes gelatinous a further 80—100 c.c. of 72% sulphuric acid is added, and the mixture allowed to stand for 24 hrs. It is then diluted with 1—1.5 parts of water, passed through a Gooch filter, washed with hot water, dried to constant weight, ignited, and weighed, the difference between the two weights giving the amount of ash-free lignin.—W. J. W.

PATENTS.

Silk; Manufacture of —. J. Korselt. E.P. 108,489, 1.8.17. Conv., 31.5.16.

THE strength and elasticity of unloaded, raw, or boiled silk fibres is increased, and the subsequent weakening of the fibres is avoided or reduced by the use of catalase. In order to accelerate the catalytic action, or to keep the catalase efficient for a longer time, substances such as creatinine may be added, which act as activators on the catalase contained in or added to the silk. The catalase may be obtained by extracting liver with water, precipitating the extract by alcohol, and again extracting the dried precipitate with water. The amount of catalase in the aqueous solution may be found by titration with hydrogen peroxide. The silk is treated in a solution of 0.1—2.0% of catalase at about 40° C. during 20—40 mins.; it is then centrifuged and dried.—L. L. L.

Wool, hair, or the like, and vegetable fibres; Manufacture of —. J. Korselt. E.P. 109,051, 18.8.17. Conv., 19.9.16. (Cf. ante.)

SKINS, wool, hair, feathers, artificial silk, cotton, and other vegetable fibres are strengthened and preserved by treatment with catalase and/or perhydridase. The fibres are treated with a dilute solution of catalase and/or perhydridase for 20—40 mins., and then dried. "Dead" wool may be dyed like normal wool after treatment. Cotton or other vegetable fibres are increased in strength, elasticity, brilliancy, and absorbent power for dyestuffs. The treatment may take place at any desired stage of manufacture—for instance, before spinning, before, during, or after dyeing, or during or after finishing. Perhydridase may be extracted from calf's liver with a solution of 1% sodium bicarbonate and 2% sodium fluoride; this solution may be applied directly to the fibres. The activity of catalase can

be increased by adding 1—5% (calculated on the weight of the wool) of creatinine to the bath.

—L. L. L.

Wool; Apparatus for drying —. S. C. Wilson. E.P. 139,278, 12.2.19.

IN a closed chamber through which hot air is circulated is supported a tier of perforated trays which receive a longitudinal reciprocating motion. The wool is fed on to the uppermost tray by a vibrating feed shoot, moved forward by a series of transverse rollers operating above the tray, and delivered from the end of the tray by means of hinged shoots to the one next below, the wool being opened by means of a roller whilst passing from one tray to the next.

—L. L. L.

Waterproofing fabrics and rendering the same impermeable to gases; Adhesive composition, more especially applicable for use in —. Soc. Anon. des Etabl. Hutchinson. E.P. 129,630, 20.6.19. Conv., 6.7.18.

A COMPOSITION consisting of, e.g., caoutchouc 20 pts., cellulose acetate 60 pts., tetrachloroethane 600 pts., is applied either hot or cold to fabrics for waterproofing them or rendering them impermeable. Sulphur and an accelerator of vulcanisation may be added to the composition, and the coating may be vulcanised. Loading agents or coloured materials may also be added. The material is particularly adapted for forming the envelopes of balloons and aeroplanes.—L. L. L.

Hop bines; Manufacture of textile fibres from —. H. Küchenmeister. G.P. 318,224, 17.11.18.

HOP bines are boiled for several hours with a weak caustic alkali solution and then washed. The process is repeated, and the material is then treated with very dilute acid, washed and dried. The hop bines may be subjected to a preliminary treatment for one or more days with a neutral alkali salt solution, at normal temperature, in order to remove the epidermis. An alkali sulphite may be added to the caustic alkali solution, and the second boiling may be followed by a short treatment under pressure with an alkali bisulphite, or replaced entirely by a similar treatment of longer duration. The wet fibres may be bleached, after treatment, by means of an ammoniacal hydrogen peroxide solution.

—W. J. W.

Fabrics for airships. Vickers, Ltd., J. McKechnie, and A. Ryan. E.P. 142,615, 25.3.19.

FABRIC of cotton or other fibre, having cellulose as its principal constituent, is converted partially or wholly into cellulose acetate; after treatment with a softening agent, such as triacetin or castor oil, and calendering, the fabric is doped and varnished.

—D. F. T.

Bast fibre material; Process of opening out and simultaneously dyeing —. R. Haller. G.P. 318,271, 25.1.19.

BAST fibre raw material is boiled in an alkaline medium with addition of vat dyestuffs such as indigo, thioindigo, N-dihydroanthraquinoneazaine (Indanthrene), and sulphur dyestuffs, which react with the pectins. Alkali sulphides may be added.

—W. J. W.

Wood; Recovery of organic products from —. H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,339,489, 11.5.20. Appl., 11.8.17. Renewed 21.10.19.

WOOD is ground in a current of water which serves to carry away the pulp; the water is separated from the pulp and used again, this cycle of operations being repeated until the concentration of the organic products in the water is sufficient for the subsequent recovery process.—D. F. T.

Sulphite liquor [for cellulose manufacture]; *Process for regulating [measuring] the acidity of —*. J. B. Crandon, Assr. to Crandon Mfg. Co. U.S.P. 1,340,849, 18.5.20. Appl., 23.11.17. Renewed 25.3.20.

THE liquor is caused to form the electrolyte of an electric battery and the current produced measured. —B. M. V.

Waste liquors from sulphite- and sulphate-cellulose manufacture; Removal of water from —. E. Oman. G.P. 316,592, 26.6.17. Conv., 5.4.17.

WASTE sulphite liquors are kept agitated and subjected to a temperature below their solidification point, any snow or ice crystals formed being removed by filtration or centrifuging. Portions of liquid adhering to the crystals are diluted. The low temperature of the crystals, as well as of the concentrated liquors, may be utilised for cooling further quantities of liquor. The concentration of the liquors may be increased to 40% by this method.

—W. J. W.

Cellulose acetates; Manufacture of —. J. O. Zdanowich. E.P. 139,232, 8.4. and 18.9.18.

THE substitution of organic acids, particularly mono-, di-, and trichloroacetic acids, for sulphuric acid in the production of cellulose esters has not given satisfactory results on account of their being weak acids. If, however, the chloro-acetic acids are employed in the nascent state by adding a halogen to the acetylating mixture, they react more energetically, even at low temperatures, and have no injurious effect on the cellulose molecule at high temperatures. After the production of the mono- and di-acetate of cellulose the esterification is too slow, but the addition of a small quantity of sulphuric acid or other strong condensing agent readily completes the esterification, the cellulose passing into a clear, colourless solution of extreme viscosity. This solution may be used directly for the production of films, artificial silk, horsehair, etc. The material precipitated in the usual way forms a transparent, glass-like, tenacious material, and is soluble in chloroform or acetone.—L. L. L.

Plastic [nitrocellulose] composition. H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,339,552, 11.5.20. Appl., 1.12.19.

NITROCELLULOSE is mixed with an aliphatic hydroxy compound containing from three to five atoms of carbon and with a halogen derivative of the next lower radicle of the same homologous series.

Carbohydrate in plants, etc. E.P. 123,326. See XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Scouring and milling of fancy woollen piece goods. S. Begg. J. Soc. Dyers and Col., 1920, 36, 38—43.

THE author discusses briefly different types of piece scouring machines, and the scouring, soap milling, and acid milling of piece goods. Many advantages are obtained by acid milling compared with soap milling, particularly in the selection of dyestuffs, time of milling, and saving of soap and water.—L. L. L.

Aniline Black; Method for producing ungreenable —. A. Scheurer. Sealed note 1414, 28.8.13.

Bull. Soc. Ind. Mulhouse, 1919, 85, 292. Report by M. Battagay, *ibid.*, 293—294.

THE mixture for producing the Aniline Black consists of 35 pts. of potassium ferricyanide, 35 pts. of potassium chlorate, 65 pts. of aniline, 105 pts. of hydrofluosilicic acid of 20° B. (sp. gr. 1.16), and 760 pts. of a 12.5% starch solution. This is quite stable and does not attack steel, nor tender the fibre. The colour may be developed by steaming or ageing at 45° C. for 2 days, and is quite ungreenable by sulphurous acid. Battagay reports that the process is in accordance with the modern view that greenable blacks are produced with a strongly acid mixture, and ungreenable blacks with a feebly acidic mixture.—A. J. H.

Anthocyan; Tinctorial properties of the —. A. E. Everest. J. Soc. Dyers and Col., 1920, 36, 47—53.

THE colouring matters of the anthocyan, anthocyanin, and anthocyanidin group have an affinity for tannin-mordanted cotton, and produce fine strong shades that are fast to light; this affinity is not affected by the number, nor by the position of the hydroxyl groups, nor by ethoxy or glucoside residues, but is dependent upon the presence of the pyrylium ring. These pigments will be practically useless for technical dyeing practice. The colours do not lack tinctorial power but lack fastness to washing and are sensitive to acids and alkalis.—L. L. L.

Drying of printed fabrics; Use of steam in the —. E. Boeringer. Bull. Soc. Ind. Mulhouse, 1919, 85, 298—411.

THE general conditions governing the evaporation of water are discussed and their application to the drying of fabrics is indicated. Capillary forces are shown to influence largely the drying of a wet fabric. The methods of drying by means of hot flues, tenter frames, hot air chambers, and the usual drying cylinders are examined critically with regard to efficiency and the theoretical principles involved. Various improvements are suggested.

—A. J. H.

Finishing processes; Influence of — on woven fabrics. E. Midgley. J. Soc. Dyers and Col., 1920, 36, 35—38. (*Cf.* J., 1919, 102A.)

THE author discusses the influence of crabbing on union and wool goods; the mechanical manipulation and chemical treatment of cotton goods as illustrated in mercerising and schreinerling; and defects developed during dyeing and finishing. Unbalanced strains are present in a woven fabric as it leaves the loom, and unless the material is reduced to a state of equilibrium there would be a great tendency for the fibres and yarns to shrink irregularly and give the fabric a wrinkled or cockled appearance and make it unsaleable. During crabbing the yarn swells and becomes plastic, and in this condition readily takes any position forced upon it; this position is permanent if maintained until the fibre becomes cool. The pressure during

crabbing is an essential factor, and consequently the tension during winding is important. The degree of crabbing must be varied according to the quality of the material, the structure of the yarn, the weave and structure of the fabric, and the type of finish required. The most difficult defect to account for is produced during dyeing and finishing, namely "crimps." It is produced where the wet processes develop the shrinking properties inherent in the fabric, and being due to uneven shrinkage and movement of the fibre, an absence of uniformity in either materials or treatment during the change from fibre to finished cloth is indicated. This type of defect is also produced by artificial conditioning of yarn on bobbins.

Tannins and cotton. Wisdom. See XV.

PATENTS.

Colour effects; Method of and means for producing certain — on textile and other fabrics and materials. The Calico Printers' Assoc., Ltd., E. Schofield, and F. Farnworth. E.P. 139,373. 24.4.19.

COLOUR (or a resist, discharge, etc., mixture) is applied to one side of the fabric in such a manner as to insure saturation and penetration to the other side, and subsequently another colour or colours are applied to the opposite side by allowing them to drip or drop on to the fabric. For example, the fabric is passed through a suitable machine and the first colour is applied to one face by means of a rotating brush or the like. After drying and brushing, the travelling fabric passes under regulated taps or equivalent appliances for supplying a second colour or colours, and if desired catching troughs may be automatically interposed between the taps and the fabric to produce an intermittent or "sarric" effect.—L. L. L.

Dyeing, scouring, and washing wool and other fibrous materials; Machines for —. J. and R. Whitaker. E.P. 142,602, 14.3 and 10.9.19.

IMPROVEMENTS are claimed in the side tipping discharge movement for the hinged inner chamber of machines of the type described in E.P. 101,060 and 108,809 (J., 1916, 961; 1917, 1045).

Hosiery-dyeing machine. Fabric-treating device. Fabric-treating machine. Dyeing device. H. M. Dudley. U.S.P. (A) 1,330,246, (B) 1,330,247, 10.2.20, (C) 1,331,743, and (D) 1,331,744, 24.2.20. Appl., (A) 19.7.18, (B) 21.1.19, (C) 18.2.18, (D) 27.2.18.

(A) A SERIES of dyeing chambers with non-perforated ends and foraminous sides are mounted on a common axis. Means are provided for revolving the chambers, for passing liquid through them in opposite directions, and for impinging the liquid evenly upon the foraminous sides of the chambers. (B) A rotary dyeing chamber contains a rotary fabric chamber. Means are provided for continuously revolving the two chambers and for passing a liquid and a gas through them. (C) A receptacle contains a series of rotary hollow foraminous reels upon which fabric may be wound. Means are provided for revolving any reel while the others are held stationary, and some of the openings of the reels may be closed by means of a sliding device. Provision is made for continuously forcing liquid outwards from the interior of each reel or for continuously drawing liquid into the interior of each reel through fabric wound thereon. (D) A series of dyeing chambers is provided with sectional foraminous cylinders upon which fabric may be wound. A resilient device is provided for forcing the foraminous cylinders against the inner faces of the rolled fabrics, and a device for forcing liquid through the fabrics wound upon the cylinders.—L. L. L.

Dyeing machine. H. M. Dudley. U.S.P. (A) 1,333,217 and (B) 1,333,218, 27.4.20. Appl., 25.1 and 6.3.18.

(A) WITHIN a dyeing machine is a series of fibre chambers, perforated at bottom and top (the relative positions of which can be varied), and each containing a sliding perforated plate. A liquid can be forced or drawn from a lower liquid chamber, through the fibre chambers and so into an upper liquid chamber. (B) A dyeing machine contains a series of dyeing chambers, the ends of each being perforated and movable so that their relative positions can be varied and the contained fibre be compressed. A liquid can be forced in one direction and drawn in the opposite direction through the dyeing chambers.—A. J. H.

Dyeing of furs and other materials; Electrical process and apparatus for — and products resulting therefrom. J. E. Bloom. U.S.P. 1,338,353, 27.4.20. Appl., 30.9.19.

FUR, or other fibrous material, is electrified with one sign only, by bringing it in a dry state, under insulated conditions, into physical contact with a conductor extension of one terminal of a direct current supply of suitable voltage and amperage, the other terminal being earthed, and with a suitable increased difference of potential between the electric source and the extension contact.

—B. N.

Hair; Process of treating —. H. R. Anders, Assr. to The Roessler and Hasslacher Chemical Co. U.S.P. 1,331,609, 24.2.20. Appl., 24.5.17.

HAIR is treated with a bath containing zinc dust and acetic acid, then washed with a solution of soap and sodium carbonate, and treated with hydrogen peroxide solution rendered alkaline with ammonia.—L. L. L.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Manufacture of — by the chamber process. Kaltenbach. Chim. et Ind., 1920, 3, 407—421.

THE use of a series of tubes is recommended in place of lead chambers; the gases from the Glover tower are passed, in parallel, through the tubes in one or several series. Each tube is packed with a suitable filler and is surrounded by a water jacket. The necessary pumps and pipes are provided for circulating and supplying weak acid or water to the tubes and towers.—W. P. S.

Nitric acid; Production of concentrated — from nitrous gases. F. Foerster, T. Burchardt, and L. Fricke. Z. angew. Chem., 1920, 33, 113—117, 122—127, 129—132.

THE authors contradict their earlier contention (J., 1908, 1110) that only nitric acid with the lowest vapour pressure can be produced by the interaction of weak nitric acid with nitrogen peroxide, oxygen, and water. The process requires a lengthy time of treatment, however, as well as only slight excess of oxygen, and a low gas velocity. These latter factors tend to militate against

effective reaction, and under the most favourable conditions a concentration of only 80% is obtainable. Nitric acid of the highest concentration may be produced by treating the dilute acid with liquid nitrogen peroxide in sufficient excess, and then lightly agitating the mixture with oxygen.

—W. J. W.

Ammonia oxidation [; *Theoretical aspects of* —]. J. Baumann. Chem.-Zeit., 1920, 44, 145–146.

Of the two reactions $2\text{NH}_3 + \text{O}_2 = 2\text{NO} + 3\text{H}_2\text{O}$, and $2\text{NH}_3 + \text{O}_2 = \text{N}_2 + 3\text{H}_2\text{O}$, the latter is more exothermic, and undue heating of the apparatus beyond the contact chamber indicates that the reaction is taking place more in accordance with the second equation, resulting in a low yield. The exothermic character of the reaction is due to combustion of the hydrogen of the ammonia, and a hydrogen flame burning in a tube may give rise to the phenomenon of a "singing flame." The yield diminishes with increasing pitch of the note sounded.—W. J. W.

Nitrous acid; Action of — on coloured indicators.

C. Matignon and G. Gire. Bull. Soc. Chim., 1920, 27, 362–366.

From titrations of a mixture of nitrous and nitric acids in the presence of different indicators, it is shown that, contrary to the conclusions drawn from the heats of neutralisation (J., 1920, 188A), nitrous acid is a much stronger acid than the second acid function of phosphoric acid. This result is confirmed by electric conductivity measurements which indicate that the electrolytic dissociation constant of nitrous acid is 6×10^{-4} as compared with 1.9×10^{-7} for the second acid function of phosphoric acid.—W. G.

Arsenic acid; Iodometric determination of —.

P. Fleury. J. Pharm. Chim., 1920, 21, 385–391.

A QUANTITY of arsenate equivalent to about 50 c.c. of N/10 iodine solution is dissolved in 30 c.c. of water, 3 c.c. of hydrochloric acid (sp. gr. 1.171) is added, and the mixture heated on a boiling water-bath for 5 mins.; sufficient potassium iodide is then added to give a 25% solution, the heating continued for 5 mins., the mixture cooled, and the liberated iodine destroyed by the addition of thio-sulphate solution. Titration of the iodine does not give a reliable measure of the arsenic acid, because a small quantity of iodine is invariably liberated by the action of dissolved oxygen on the hydriodic acid. The colourless mixture is, therefore, treated with an excess of sodium bicarbonate and the arsenious acid titrated with N/10 iodine solution.

—W. P. S.

Solvay ammonia-soda process; Combination of — with processes for manufacturing nitrogen compounds. L. Hamburger. Chem. Weekblad, 1920, 17, 256–258.

AMMONIA produced by any nitrogen fixation process may be utilised for the Solvay process, the latter being worked to yield ammonium chloride, which may be employed for the manufacture of artificial manures. This method obviates the lime treatment in the Solvay process and eliminates the necessity for sulphuric acid in producing fertilisers. In the manufacture of urea from sodium cyanate an ammonium salt of a strong acid may be used.

—W. J. W.

Sulphate of ammonia; Manufacture of neutral —. F. Shewring. Gas World, 1920, 72, 453.

NEUTRAL ammonium sulphate may be obtained by passing ammonia from the weak ammoniacal liquor plant into the evaporating pans by means of a perforated lead pipe. In plants where ejectors are used for removal of the salt, it is important to keep the ammonium sulphate acid, as an alkaline

solution will cause blockages in the condensing plant. In the centrifuges the salt may be sprayed with weak ammonia solution to reduce the acidity, but an entirely neutral salt will not often result. To remove the acidity entirely, the salt is laid on a table with a false bottom, and while still moist is covered by means of a wooden hood provided with a vent pipe. Ammonia gas is passed through a lead pipe, with drilled holes and flattened end, laid beneath the false bottom, and is allowed to pass through the salt till neutralisation is complete.—W. J. W.

Ammonium sulphate; Melting point of normal —.

C. Caspar. Ber., 1920, 53, 821.

WHEN heated in an open tube, normal ammonium sulphate softens at about 310°C ., melts at 336°C ., 339°C ., and decomposes with evolution of gas at 355°C .; in a sealed tube it softens from about 360°C ., and has m.p. 417°C – 423°C . The datum, 140°C ., recorded in the literature is based on a misunderstanding, and really refers to ammonium bisulphate (cf. Watson Smith J., 1895, 629; 1896, 3).—H. W.

Calcium cyanamide; Yields in the manufacture of —. C. Pluvinage. Chim. et Ind., 1920, 3, 438–439.

THE conversion of calcium carbide into cyanamide is never complete under ordinary conditions of manufacture; a portion of the carbide remains unconverted, the nitrogen employed contains neon, argon, etc., and a quantity of cyanogen is formed, the amount varying with the temperature, pressure, and rate of reaction. Further, normal commercial carbide yields about 300 l. of acetylene per 1 kg., a quantity corresponding to 81.87% of pure carbide. If the calcium cyanamide obtained from such carbide contains 22.5% of nitrogen, 19% of the carbide has escaped reaction; if it contains 26% of nitrogen, 2% of the carbide has not reacted.—W. P. S.

Calcium carbide and nitrogen; Variety of carbon formed in the reaction between —. A. Remelé and B. Rassow. Z. angew. Chem., 1920, 33, 139–140.

SMALL quantities of carbonaceous matter remain after the decomposition of calcium cyanamide with water. When purified by fusion with potassium hydroxide or treatment with hydrofluoric acid this matter contained 98.15–99.4% C, 0.13–1.61% H, and 0.43–1.18% of residue. It had sp. gr. 2.250, ignited at 600°C – 610°C ., and had the characters of a pure graphite. (Cf. J.C.S., July.)—C. A. M.

Sulphites; Estimation of —. H. I. Waterman. Chem. Weekblad, 1920, 17, 196–197.

THE oxidation of sulphite solutions in air is especially rapid in presence of hydroxyl ions, for example, in solutions of normal sodium sulphite. Sulphite may be accurately estimated by dissolving the salt in a boiled 5% glycerol solution in a flask filled with carbon dioxide. A measured quantity of this solution is run into a known volume of acidified standard iodine solution under carbon dioxide. The excess of iodine is titrated with thiosulphate.—W. S. M.

Nitrites; Sensitive reaction for —. P. H. Hermans. Pharm. Weekblad, 1920, 57, 462–463.

TO 2 c.c. of the solution to be examined a few drops of glacial acetic acid are added and then 2 c.c. of 5% potassium oxalate solution, 1 c.c. of 5% manganous sulphate solution, and a few drops of 3% hydrogen peroxide. A red coloration indicates nitrate (cf. 1919, 574 A; 1920, 283 A). 0.02 g. of sodium nitrite per l. can be detected in this way.

—W. S. M.

Potassium phosphate; Reactions between primary — and increasing quantities of calcium bicarbonate during boiling. W. Windisch and W. Dietrich. *Woch. Brau.*, 1920, 37, 177—180, 187—189.

If solutions of primary potassium phosphate are boiled with increasing proportions of calcium bicarbonate the resulting precipitates show increasing percentages of calcium corresponding to a transition from secondary to tertiary calcium phosphate, and the increase in alkalinity of the filtrate (due to formation of secondary potassium phosphate) becomes less rapid as the proportion of bicarbonate is increased. The alkalinities of the filtrates (found from surface tension measurements with eucupine dihydrochloride as indicator; *J.*, 1920, 461 A) are lower than the calculated values, the differences being ascribed to entrainment of soluble alkaline compounds with the precipitates.—L. E.

Chromic chloride solutions; Action of neutral chlorides upon —. M. E. Baldwin. *J. Amer. Leather Chem. Assoc.*, 1919, 14, 10—19.

THE hydron concentration of solutions containing the same amount of chromic chloride but varying amounts of sodium, potassium, ammonium, lithium, and barium chlorides, increases directly with the amount of added salt. The power of increasing the hydron concentration was in the following order of increasing effect of chlorides:—K, NH₄, Na, Li, Ba, which are also in their order of increasing power of forming hydrated ions at infinite dilution. This explains their action on the hydron concentration, since the hydration of the neutral solute ions diminishes the amount of water functioning as solvent. The increased hydron concentration is, therefore, not due to further hydrolysis of the chromic salt. (*Cf. J.*, 1920, 123A.) —D. W.

Rare earths; Separation of the — by basic precipitation. W. Prandtl and J. Rauchenberger. *Ber.*, 1920, 53, 843—853.

THE authors suggest a modified process for the basic separation of the rare earths, based on the reversible reaction, $MCl_3 + 3NH_4OH \rightleftharpoons M(OH)_3 + 3NH_4Cl$, which can be employed at any dilution and which depends mainly on delaying the precipitation by the addition of a sufficiency of ammonium chloride. The equilibrium has been investigated for lanthanum, neodymium, and praseodymium in the presence of ammonium chloride solution in concentration varying from *N*/1 to 5*N* and for temperatures ranging from 15° to 100° C. The results show that the precipitates are composed of strongly basic chlorides of varying composition, the solubility of which increases to a maximum with 3*N* ammonium chloride solution and then diminishes. The earth salt is absorbed from its solution by the precipitate to a marked degree. Lanthanum is relatively easily separated from didymium by reason of its greater basicity, but neodymium and praseodymium differ little in this respect. The temperature of the solution is an important factor in the separation of the earth metals. Lanthanum may be comparatively readily separated from neodymium and praseodymium by the following method even when the latter are present in considerable amount. The impure oxide is dissolved in moderately concentrated hydrochloric acid so as to form a nearly neutral solution, an amount of ammonium chloride equal to the weight of the oxide is added, followed by sufficient water to make the solution 2—3*N* with respect to ammonium chloride. The solution is heated to 50° C. and a mixture of equal volumes of 4*N*-ammonia and 4*N*-ammonium chloride solution is slowly added with constant shaking. As soon as a moderate amount of precipitate has formed (about 5% of the original oxide), the operation is interrupted, the precipi-

tate is removed, and a second precipitation is effected in the clear filtrate. Alternate precipitation and filtration are continued in this manner until the filtrate no longer exhibits absorption lines. (*Cf. J.C.S.*, July.)—H. W.

Radium-barium solution; Crystallisation of a —. C. E. Scholl. *J. Amer. Chem. Soc.*, 1920, 42, 889—896.

PURIFICATION of radium salts from barium salts is more efficiently carried out by crystallisation of the bromides than by crystallisation of the chlorides. A saturated solution of the bromides in 0.33*N* hydrobromic acid deposits 1/3 of the dissolved solid on cooling from 100° C. to 0° C. Crystallisation of such a solution gives a rapid concentration of the radium: thus if the concentration of radium in the starting material be represented by 1.0 the 9th crystallising dish to the right has a concentration 62 and the 9th to the left 0.016. In the fractionation the crystals of any crystallisation are moved 2 dishes to the right and the liquors 3 dishes to the left. (*Cf. J.C.S.*, July.) —J. F. S.

Red phosphorus as a reducing agent. L. Rosenstein. *J. Amer. Chem. Soc.*, 1920, 42, 883—888.

RED phosphorus when boiled in acid solutions of various salts exerts a strong reducing action. Gold and silver salts are converted into insoluble phosphides; mercurous or mercuric salts are reduced to the metal; palladium and osmium salts are reduced either to the metal or to the phosphide; stannic, ferric, and iridic salts are reduced respectively to stannous, ferrous, and iridous salts. Selenates are reduced either to the element or an insoluble phosphide, molybdates to quadrivalent molybdenum salts, vanadates to trivalent vanadium salts, bichromates to chromic salts, and permanganates to manganous salts. Bismuth, lead, cadmium, antimony, and arsenic salts, arsenates and stannous salts are not reduced, whilst tellurates and chloroplatinates are only slowly reduced.—J. F. S.

Hydrogen peroxide; Acceleration of decomposition of — by colloidal rhodium. C. Zenghelis and B. Papaconstantinos. *Comptes rend.*, 1920, 170, 1178—1180.

THE decomposition of hydrogen peroxide by a colloidal solution of rhodium is a unimolecular reaction, the velocity of which is considerably accelerated by previously bubbling either hydrogen or carbon monoxide through the colloidal solution. —W. G.

Graphitic carbon [and graphitic acid]; Problem of determining —. W. A. Selvig and W. C. Ratliff. *Trans. Amer. Electrochem. Soc.*, 1920, 629—658.

STAEDENMAIER'S method (*J.*, 1898, 880; 1899, 716) is inapplicable in presence of a large proportion of amorphous carbon as it leads to explosion. Anthracite and bituminous coal give no graphitic acid by Brodie's method (*Phil. Trans.*, 1859, 149, (1), 249), but coke yields a small amount. The conversion of graphite to graphitic acid by this method is assisted by treatment with potassium permanganate and sulphuric acid after the green stage is reached. The oxidation of the graphite takes place more readily with fine powders, as in the case of Acheson graphite. Moisture in graphitic acid cannot be estimated by ordinary methods, as the substance is extremely sensitive to varying humidity. Carbon and hydrogen in natural and artificial graphites may be determined by careful combustion after an admixture of a non-combustible material such as copper oxide; a preliminary treatment for removal of volatile matter and carbonates may be carried out. For determining graphitic carbon by conversion to graphitic acid

0.5 g. samples of Ceylon, Alabama, Pennsylvania, and Acheson graphites were treated by the Brodie and Staudenmaier methods. Mixtures of 0.5 g. of graphite and 0.5 g. of amorphous carbon were also treated by the Brodie method. Staudenmaier's method gave figures about 1.5–2.5 higher than those obtained by Brodie's method, and both these methods showed a lower percentage of carbon than was indicated by direct combustion of the graphites. These differences were greatest with Alabama and Pennsylvania samples. The gases evolved during treatment were found to consist chiefly of carbon dioxide, which is probably the final product of a series of oxidations which the graphite undergoes on treatment with the oxidising mixtures. The oxidation of carbon to graphitic acid evidently takes place within narrow limits of oxidising agent, temperature, and time. Loss of carbon as carbon dioxide is greater with Alabama and Pennsylvania graphites than with Ceylon and Acheson samples.—W. J. W.

Graphitic acid—a colloidal oxide of carbon. G. A. Hulett and O. A. Nelson. Trans. Amer. Electrochem. Soc., 1920, 425–439.

THE moisture content of graphitic acid, as of other colloids, cannot be determined by the usual methods. A method used for determining the true moisture of coals (Amer. J. Sci., 40, 175; cf. J., 1917, 378) was applied, in which the substance is heated *in vacuo* and the moisture condensed at -78°C ., the other gases being pumped off by a mercury pump. By plotting moisture-temperature curves and noting when decomposition becomes measurable, the moisture content can be found by interpolation. Considerable amounts of water can be removed from graphitic acid without decomposition, but at 181°C . there are indications of slow decomposition, and at 218°C . explosion takes place. The vapour pressure of graphitic acid, on removing successive quantities of water, was determined. The results obtained at 25° and 56.5°C . indicate that the vapour pressure continually decreases with removal of water without suggestion of a break. Graphitic acid is assumed to be a colloidal oxide of carbon, the flakes being made up of an infinite number of exceedingly thin plates covered with absorbed water. This explains the relation of water to the substance and the divergent properties of different varieties caused by variable size of the plates. Graphitic acid appears to have a formula of the order C_xO or C_xO_y .—W. J. W.

Detection of nitrates. Groenewege. See XXIII.

PATENTS.

Sulphuric acid manufacture; Heat interchangers for contact process of —. P. Audianne. E.P. 142,522, 7.12.18.

A HEAT interchanger for use in sulphuric acid manufacture comprises a vertical steel cylinder containing a set of tubes, arranged close together, and throttled at their lower end by a device which consists of a screw with three threads, or other similar arrangement for imparting a rotary movement to the gas. At the top and bottom of opposite sides of the cylinder are two openings, and in a continuation of the cylinder below is a third opening at right angles to the other two. The upper portion of the apparatus terminates in a truncated dome with internal concentric conical portions spaced so as to allow equal volumes of gas to pass between, and having an opening at the top communicating with the contact chamber. The cold sulphurous gases enter the lowest opening and

pass up through the tubes and the dome to the contact chamber, after leaving which they enter the tube container at its upper end and pass round the tubes to the lower exit. The dimensions and number of the tubes are dependent on the output of the sulphur trioxide plant, their total surface being 5 sq. m. per ton of gas passing through the apparatus in 24 hrs. for a temperature of 220°C ., and 25 sq. m. for a temperature of 325°C . The total cross-sectional area of the tubes should be substantially equal to that of the space outside. The diameter of the cylinder is selected to give a linear gas velocity greater than 3½ m. per sec.

—W. J. W.

Sulphuric acid concentration. J. Patten, Assr. to S. M. Shoemaker. U.S.P. 1,310,290, 18.5.20. Appl., 30.12.18.

IN connection with a series of concentrators (U.S.P. 1,291,827; J., 1919, 361A), two valves are introduced for the feed, and two receivers are provided, from either of which the acid may be transferred to the other.—W. J. W.

Hydrochloric acid; Apparatus for producing — utilising sludge acid [from treatment of mineral oils]. H. M. Lasher, Assr. to The Kansas City Refining Co. U.S.P. 1,339,519, 11.5.20. Appl., 7.10.16.

A GENERATOR for hydrogen chloride is connected to an absorber, consisting of a conduit with opposite and alternate baffles, which communicates with an absorption tower packed with filling material. Water is admitted at the top of the tower, and flows out at the base into a chamber, whence it is conveyed to the first absorption apparatus, the latter being provided with a receiving tank to receive the acid solution.—W. J. W.

Nitric acid; Manufacture of concentrated — from dilute nitric acid. E. Reinau. G.P. 305,171, 30.9.16. Addn. to 299,001 and 299,007 (J., 1920, 449A.)

AN alkali nitrate and sodium bisulphate, produced from dilute nitric acid as previously described, are allowed to interact, baking of the mixture and formation of pyrosulphate being prevented by conducting the process under 400 mm. vacuum at the start, and at an initial temperature of 90° , rising to 140°C .—W. J. W.

Electrolysis of metal salt solutions. Fredriksstad Elektrokemiske Fabr. A./S., F.E.F. E.P. 138,862, 31.12.19. Conv., 13.2.19.

IN an apparatus for the electrolysis of alkali chlorides a sloping layer of loose granular material of the substance to be electrolysed separates the anode and cathode compartments, and is supported on a wire cloth cathode and superposed asbestos cloth, arranged at such an inclination that the granular material is distributed over the support by the action of gravity. The granular soluble substance is supplied as required, to compensate for the quantity dissolved, through an opening along the upper edge of the layer, and a partition, the lower edge of which dips into the electrolyte, prevents the passage of gas into the charging opening, directing it into a gas-collecting chamber. A number of inclined anodes are placed in the space above the separating layer, with their lower ends resting on a stationary wall, several cells being so arranged that the bottom wall of one cell forms the inclined cover of the adjacent cell.—B. N.

Ammonia; Synthesis of — at very high pressures. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 142,150, 21.9.18. Conv., 20.2.18.

FOR the synthetic production of ammonia at pressures above 500 atm. or even 2000 atm. (E.P.

130,086—7; J., 1919, 718 A). use is made of a single catalytic apparatus instead of several. After circulating round a tube containing the catalyst and attaining the temperature of reaction from the tube itself during working and by a heating coil at starting the gases are caused to enter the tube. Successive series of pipes conduct the ammonia formed from the interior of the tube to collectors provided with cooled walls and having an outer insulated tube communicating with the interior of the catalyst tube by means of which the gases freed from ammonia are returned to another portion of the catalyst. In a modification of the device the reacting gases are heated by traversing a central tube through the catalyst after which they enter the head of the catalyst tube, the products being withdrawn as before.—W. J. W.

Ammonia; Synthetic production of —. H. C. Greenwood. U.S.P. 1,337,903, 20.4.20. Appl., 15.2.18.

In the production of ammonia from hydrogen and nitrogen one of the gases is passed over an alkali amide before passing the mixture of gases over the catalyst.—W. J. W.

[Calcium] cyanamide; Process and apparatus for manufacture of —. A. Duchemin. E.P. 142,354, 30.6.19.

FINELY powdered carbide is placed in a sheet-iron crucible, having a perforated base covered with a layer of asbestos or the like. The crucible is enclosed in brickwork, which serves as a heat regenerator and is itself surrounded by an insulating jacket, consisting of two sheet-iron plates with asbestos between. A lid operated by a pivoted lever covers the whole device. Nitrogen enters the furnace at the base, passing through the asbestos in the jacket to the top of the brickwork, through openings in which it then enters the crucible and passes downwards to an exit. Initial heating of the carbide is effected by introducing a receptacle containing a mixture of two substances which react on each other, such as an alkali or alkaline earth metal and an oxide or halide of another metal, the reaction being started by a suitable priming, percussion cap, or an electric current. The brick casing serves to maintain the heat necessary for the interaction of the carbide and nitrogen.—W. J. W.

Calcium cyanamide; Apparatus for improving the grade of —. G. E. Cox, Assr. to American Cyanamid Co. U.S.P. 1,331,742, 24.2.20. Appl., 20.8.18.

A NITRIFYING apparatus for the manufacture of calcium cyanamide consists of a combustible container adapted to hold finely divided calcium carbide, a hollow central core for the container, and a hinged outer form for holding the container.

—L. L. L.

Crude calcium cyanamide; Process for continuous manufacture of —. M. Novak. G.P. 305,061, 18.10.16.

THE furnace consists of a single reaction chamber in which, after admission of the nitrogen, the material is at once heated to the reaction temperature, and from which it is removed whilst hot immediately the process is completed. The material may first be deprived of free oxygen by keeping it for a short time in an atmosphere of nitrogen in another chamber immediately preceding the furnace.

—W. J. W.

Crude calcium cyanamide; Process for electrically heating the reacting materials in the manufacture of —. M. Novak. G.P. 305,532, 22.10.16. Addn. to 305,061 (preceding).

THE iron rails on which run trolleys carrying the charge may be employed for carrying the electric

current to the furnace, from which it is conveyed by conductors arranged along the furnace walls.

—W. J. W.

Crude calcium cyanamide; Process for decomposing —. Chem. Fabr. Kalk Ges. G.P. 301,321, 2.8.16.

IN the decomposition of crude calcium cyanamide by means of water or steam, in presence of carbon dioxide, at a high temperature, and at normal or increased pressure, ammonium salts may be added in sufficient quantity to interact with the free or combined lime, ammonia being evolved.—W. J. W.

Cyanamides [and nitrides] of the alkalis and alkaline earths; Process of decomposing —. Chem. Fabr. Kalk Ges. G.P. 302,461, 13.2.17. Addition to 301,321 (preceding).

IN the decomposition of cyanamides and nitrides of the alkalis and alkaline earths by water or steam, in presence of carbon dioxide or solid or liquid inactive materials, ammonium salts may be added either in the solid state or in solution. By this means appreciable quantities of alkali or alkaline-earth salts are obtained.—W. J. W.

Hydrate of alumina and similar gelatinous precipitates; Process for depositing — from their salts. M. Buchner, Assr. to The Chemical Foundation, Inc. U.S.P. 1,337,191, 20.4.20. Appl., 27.1.15. Renewed 26.6.19.

NON-COLLOIDAL hydroxides of aluminium, and of other metals which form colloidal hydroxides, may be prepared by dry interaction between a salt of the metal and an alkali.—W. J. W.

Metallic hydroxides; Manufacture of —. M. Buchner, Assr. to The Chemical Foundation, Inc. U.S.P. 1,337,192, 20.4.20. Appl., 26.8.15. Renewed 26.6.19.

METALLIC hydroxides, which may be easily filtered and washed, are formed by treating salts of the metals with a large excess of ammonia, the reaction liquor being used for treating a fresh quantity of salt, in presence of ammonia.—W. J. W.

Sulphur dioxide; Apparatus for producing —. H. K. Lyon. U.S.P. 1,337,561, 20.4.20. Appl., 17.7.19.

A FURNACE for obtaining sulphur dioxide from ores comprises a fire-box with an air inlet, means for heating the fire-box and for preheating the ore above the fire-box before introducing it into the box, and a heating chamber above, and communicating with, the fire-box but separate from the pre-heater.

—W. J. W.

Sal-ammoniac (ammonium chloride); Metamorphous —. C. Pfanstiehl, Assr. to Special Chemicals Co. U.S.P. 1,337,665, 20.4.20. Appl., 19.2.19.

PRESSURE is applied to crystalline ammonium chloride in order to obtain a solid mass having the appearance and fracture of marble.—W. J. W.

Ammonium sulphate; Preparation of — from calcium sulphate and gas-liquor. C. Otto und Co. G.P. 299,622, 24.3.16.

ANY ammonia not converted into sulphate by the calcium sulphate is expelled from the liquor after the reaction by passing hot or cold purified coal gas through it, and the gas is then added to the crude coal gas leaving the retorts, the ammonia combining with carbon dioxide present in the crude gas.

—A. B. S.

Ammonium compounds; Recovery of — from urine. H. Wichelhaus and J. Angerstein. G.P. 316,757, 2.10.18. Addition to 313,271.

AMMONIUM chloride, obtained by treatment of the end liquors from the production of potassium salts

with urine (J., 1919, 901A), may be separated in the form of a double salt with magnesium chloride. The liquor remaining after complete conversion of the magnesium chloride into the double salt may be run to waste with impunity.—W. J. W.

Alunite; Process of treating —. W. F. Downs. U.S.P. 1,338,428, 27.1.20. Appl., 14.12.17.

ALUNITE is treated with a dilute mineral acid, then mixed with an alkali oxide compound, and heated to about 500° C. The sulphates and other water-soluble compounds are removed by dissolving in water and filtering, the insoluble portion is mixed with sodium carbonate and heated to 950° C. to convert the alumina into sodium aluminate, which is subsequently recovered by treatment with water.

—W. J. W.

Asbestos; Method of and apparatus for treating —. O. H. Cilley, Assr. to C. G. Sargent's Sons Corp. U.S.P. 1,338,613, 27.1.20. Appl., 9.1.20.

THE lighter impurities in asbestos are removed by dry dusting, and the heavier non-fibrous impurities by washing. The water is then removed by draining and pressing, and the fibres are finally opened up and dried.—W. J. W.

Asbestos; Process of treating —. E. H. Garcin. U.S.P. 1,340,535, 18.5.20. Appl., 5.12.19.

ASBESTOS fibres are separated and strengthened by treatment with water and steam, followed by crushing between rollers, after which the asbestos is subjected to an acid bath, washed, and mechanically treated. Crushing and acid treatment may precede the steam and hot-water washing, the asbestos then being pressed, mechanically picked while wet, and finally dried; or the fibres may be softened in hot water, passed through crushing rolls, subjected to an acid bath, washed with steam and hot water, freed from water by squeezing through rollers, mechanically picked, and dried.—W. J. W.

Zinc oxide; Treating —. F. G. Breyer and E. H. Bunce, Assrs. to The New Jersey Zinc Co. U.S.P. Burdick. U.S.P. 1,339,494, 11.5.20. Appl., 29.1.19.

(A) Zinc oxide is caused to gravitate in a thin layer through a highly heated atmosphere. (B) Zinc oxide is caused to slide by the action of gravity and without mechanical agitation through a chamber arranged to offer a certain resistance through friction of the walls, the material being strongly heated during its passage.—W. J. W.

Oxides of nitrogen; Process of and apparatus for treating gas mixtures containing —. C. L. Burdick. U.S.P. 1,339,491, 11.5.20. Appl., 29.1.19.

A GASEOUS mixture containing one or more oxides of nitrogen is submitted to catalytic oxidation; the resulting nitrogen peroxide is absorbed in an aqueous medium and any mist entrained in the issuing gases removed by precipitation; the apparatus for these operations consists of a series of connected units each including a precipitator and a catalytic oxidation chamber.—D. F. T.

Sodium cyanide; Process of making —. A. Kaufman, Assr. to Air Reduction Co., Inc. U.S.P. 1,339,706, 11.5.20. Appl., 2.5.17.

IN the manufacture of cyanide by interaction of an alkali metal compound with carbon and nitrogen under the influence of heat, and alkali compound is previously intimately mixed with a carbon mass containing a small proportion of carbonised material of high porosity and absorptive capacity. By this means such fusing of the reaction product as would cause solidifying on cooling is avoided.—W. J. W.

Sulphur monochloride; Preparation of —. Chem. Fabr. Rhenania. G.P. 298,581, 11.12.14.

CHLORINE gas is passed upwards through a

series of vessels containing fragments of sulphur and the sulphur monochloride formed flows out to a receiver, any dissolved sulphur being converted into sulphur chloride by the incoming chlorine. Any sulphur chloride present in the gases leaving the last chamber of the series may be utilised for preparing vulcanised oil (rubber substitute) or the like.

—A. B. S.

Gases containing sulphur dioxide and hydrogen sulphide; Process for purifying —. J. Terwelp. G.P. 300,035, 14.2.17.

THE gases are passed through the carbonate, oxide, or hydroxide of an alkaline-earth metal or of magnesium to remove sulphur dioxide, and the hydrogen sulphide is then absorbed by alkali carbonate solution. The process is especially applicable to producer-gas.—A. R. P.

Alkali azide; Preparation of —. O. Matter. G.P. 302,561, 24.11.16.

NITROUS oxide, preferably under pressure, is passed over molten alkali amide which is vigorously stirred until it solidifies. The mass is then powdered and again heated in the gas until no further absorption takes place. The yield of sodium azide is over 90% of the theoretical. The reaction product, which contains some alkali hydroxide, is dissolved in water and the solution concentrated under reduced pressure, when the pure azide, which is only slightly soluble in strong caustic alkali solutions, is precipitated.—A. R. P.

Gases containing carbon dioxide; Utilisation of impure —. F. Riedel. G.P. 315,019, 25.11.17.

THE gases are treated with an alkali carbonate solution, and carbon dioxide is recovered by strongly heating the bicarbonate solution produced, so that steam under pressure is generated simultaneously. The carbon dioxide is suitable for use as a fertiliser (J., 1920, 125A), any injurious gases being dissolved by the condensed water deposited in the mains.—W. J. W.

Calcium sulphide; Manufacture of —. Deutscho Petroleum A.-G. G.P. 319,651, 7.8.18.

CALCIUM sulphate and methane are caused to interact at 800°–1300° C., the temperature, pressure, and velocity of the gas being controlled so as to effect complete reduction of the calcium sulphate without deposition of carbon.—W. J. W.

Ammoniacal brine; Process for carbonation of —. R. Schad. G.P. 318,180, 28.1.19.

IN the ammonia-soda process the gases containing carbon dioxide are passed through a series of vessels containing ammoniacal brine in such order that the final escaping gases are discharged from a vessel in which the whole or nearly the whole of the ammonia in solution has combined with carbon dioxide.

—W. J. W.

Liquid air; Apparatus for continuous rectification of —. E. Barbet et Fils et Cie. E.P. 142,519, 30.5.18. Conv., 9.10.17. Addition to 131,321 (J., 1919, 766A).

FOR the process described in the original patent the heat exchangers consist of bundles of tubes of great length and very small cross-section, enclosed in a shell terminating at each end in a chamber of large cross-section in which the ends of the tubes are spread out. The tubes may have small bands soldered on them at intervals to ensure equidistant spacing.—W. J. W.

Slaking lime; Apparatus for —. Spoerri & Co. E.P. 135,172, 27.10.19. Conv., 11.11.18.

Calcining lime etc. G.P. 314,584 and 317,832. See IX.

Marine alga. E.P. 123,325. See XVIII.

VIII.—GLASS; CERAMICS.

Glass resembling mother of pearl; Production of —. O. Schwarzbach. *Sprechsaal*, 1920, 53, 251—252.

VARIOUS recipes are given for the production of glass resembling mother of pearl. In each case they relate to the ground or body glass, which is repeatedly heated and cooled. Finely ground mica may be sprinkled on the hot body-glass as it is withdrawn from the melting pot, after which it is covered with a semi-crystal or crystal glass. The best opacifying medium is bone ash or cryolite, with or without zinc oxide. The cryolite may be replaced by felspar, kaolin, or fluorspar. The colour of opal glasses containing fluorides usually fades on repeated heating. The lustre may be intensified by reheating the finished glass in a reducing atmosphere.

—A. B. S.

Silicates and quartz; Prolonged action of carbonic acid on —. C. Matignon and Marchal. *Comptes rend.*, 1920, 170, 1184—1186.

CARBON dioxide under a pressure of 10 atm. has been allowed to act for ten years and three months on aqueous suspensions of quartz, wollastonite, diopside, mica, talc, asbestos, and glass respectively. At the end of that time all of the silicates and the quartz itself were more or less corroded, and varying amounts of silica had passed into solution. Wollastonite showed the greatest signs of attack, and glass the least.—W. G.

Clays; Classification of — on a ceramic basis. A. S. Watts. *J. Amer. Ceram. Soc.*, 1920, 3, 247—251.

A CLASSIFICATION based on five properties: colour, shrinkage, bonding strength, vitrification, and fusion, each property (except the colour) being divided into five groups ranging from "low" to "high," is suggested, the following limits being recommended: Colour: White, cream, buff, tan.

	Low.	Medium low.	Medium	Medium high.	High.
Shrinkage on drying	0-3%	3-6%	6-9%	9-12%	above 12%
Shrinkage total, cone 10	0-4%	4-8%	8-12%	12-16%	above 16%
Bonding strength, modulus of rupture, 50% clay—50% standard sand (lb.)	0-100	100-200	200-400	400-800	above 800
Vitrification (expressed in Orton cones)	below 5	5-15	15-25	25-30	above 30
Fusion (expressed in Orton cones) ..	below 5	5-15	15-25	25-30	above 30

—A. B. S.

Magnesia refractories. J. S. McDowell and R. M. Howe. *J. Amer. Ceram. Soc.*, 1920, 3, 185—246.

A COMPILATION of the chief information previously published on the occurrence, properties, and uses of magnesia as a refractory material with a selected bibliography. Magnesite bricks of good quality should have true sp. gr. 3.44—3.60, apparent sp. gr. 2.60—2.75, porosity 24—30%, crushing strength 5000—8600 lb. per sq. in., mean specific heat between 0° and 1300° C. 0.391, thermal conductivity 0.0085 at 1000° C., electrical resistivity 6000 ohms per cm.² at 1300° C., and average linear expansion 1.94% at 1200° C. under a pressure of 25 lb. per sq. in. Microscopic investigation shows that in the production of dead-burned magnesia any iron oxide present enters into solid solution with the magnesia crystals and forms magnesioferrite, but its chief value is its catalytic effect in hastening the forma-

tion of periclase. A small amount of silica appears to form a useful bond, consisting chiefly of forsterite, 2MgO.SiO₂. When silica and lime are both present they form with the magnesia mixtures of lower melting point than when only one of these oxides is present with the magnesia.—A. B. S.

[*Refractory materials; Measurement of physical properties [of —] at high temperatures.* A. G. Tarrant. *Faraday Soc.*, Dec., 1919. [Advance proof.]

To determine thermal expansion a cylindrical test piece, 4 in. long by $\frac{3}{8}$ in. diam., is enclosed at the bottom of a long tube of pure electric furnace graphite, which is heated in a vertical nichrome-wound electric furnace. On top of the test piece rests a plunger, which at the top of the tube is connected with a lever magnifying arrangement. Temperatures up to 900° C. are measured with a nichrome-constantan thermo-couple, and above this temperature with a Holborn-Kurlbaum optical pyrometer. Results obtained with this apparatus are concordant, but the method gives only the relative expansion of the test substance and the graphite sheath. An expansion of 0.0003 in. can be detected, and when a test-piece of pure silica is used the apparatus becomes a more sensitive temperature indicator than the thermo-couple. For measuring tensile strength at high temperatures test bars 30 in. long by $\frac{3}{8}$ in. diam. are used, with a semi-circular groove, $\frac{1}{4}$ in. deep, in the middle to localise the point of fracture. The test-bar is heated in a carbon tube furnace with a heating element consisting of a spiral cut from a solid piece of Acheson graphite. All the refractories tested were stronger at the high temperatures employed (up to 1800° C.) than in the normal "soft-burnt" condition. For testing samples in the air-dried or soft-burnt condition, a cement-testing machine is satisfactory. Attempts to measure accurately thermal conductivity at high temperatures did not give satisfactory results. For rough works routine tests, pieces in the form of shallow trays, $\frac{3}{8}$ in. thick at the bottom by 2½ in. dia., are used. A standard weight of lead is cast in each tray, and, when cold, they are placed side by side on a hot cast-iron slab, and the time taken for the lead to melt is taken as a measure of the thermal resistivity.—E. H. R.

Glass for ampullae. Ewe. *See* XX.

PATENTS.

Crucible furnaces, particularly such as are used in the treatment of glass. A. E. White. From *Fourts et Proc. Mathy Soc. Anon.* E.P. 143,117, 10.9.19.

A CRUCIBLE or glass-pot furnace, in which a crucible rests on a dished slab of refractory material from which any spilt glass is led away from the furnace through a pipe. The furnace is heated by surface combustion in a mass of porous refractory material beneath the dished slab.—A. B. S.

Glass furnaces. H. Wilkinson. E.P. 143,125, 10.11.19.

A GLASS-POT furnace having a grate beneath its eye has means for supplying solid fuel to the grate and a recuperator for preheating the secondary air before it enters the eye. It is claimed that this furnace can use an inferior coal and that it requires less fuel and less attention than either the old English or the Hermansen furnaces.—A. B. S.

Kiln for burning clay products, glazed ware and pottery. H. Webster. E.P. 133,123, 25.9.18.

A KILN with furnaces on opposite sides consists of a series of chambers connected by underground flues with a main flue and chimney. Adjacent chambers

are separated by a solid and a perforated wall respectively, the space between which forms a flue for conducting the gases from the main underground flue to the next or any subsequent chamber. Additional fuel may be supplied through feed-holes in the crown of each chamber. The chambers may be provided with muffles if desired.—A. B. S.

Refractory material. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 142,721, 19.8.19.

A REFRACTORY material, particularly suitable for lining electric furnaces operated at very high temperatures, consists of a mixture of 75–85% of fused, crystallised magnesia (sp. gr. 3.5–3.6) which has been reduced to particles of $\frac{1}{4}$ –1 in. diam., 20–10% of magnesia which has been calcined at about 700° C., and has sp. gr. 3.0–3.2, and 5% of a binder composed of magnesium chloride or other compound which forms magnesia when heated. The proportions are adjusted so that the shrinkage of the lightly burned magnesia and the binder counterbalances the slight expansion of the crystalline magnesia when the material is in use.—A. B. S.

Firebricks for furnaces, coke ovens, and the like. T. W. Keillar. E.P. 142,955, 28.2.19.

HOLLOW silica or fireclay bricks are rendered less heat-conducting by filling the cavities with lightly packed kieselguhr. The filling may be introduced through a hole which is subsequently plugged with fireclay, and the plug vitrified by means of a blast-lamp; or the filling may be inserted into the partly fired hollow brick and the cover sealed by a continuation of the firing.—A. B. S.

Silicon carbide; Formation of shaped objects of—. Gebr. Siemens und Co. G.P. 319,465, 23.2.17.

SILICON carbide is intimately mixed with a carbonaceous material, such as tar, and sand, the mixture then being moulded and heated to promote combination of the free carbon with the silicon in the sand. The process is adaptable for the manufacture of furnace bricks for use at high temperatures.—W. J. W.

Enamel; Method of cooling—. S. Wiester, Assignor to R. Weimer. U.S.P. 1,340,353, 18.5.20. Appl., 2.7.17.

A STREAM of molten enamel is subjected to the action of a jet of air moving with sufficient rapidity to separate the enamel into small particles and carry them a distance sufficient to cool them so that they will not adhere to each other.—A. B. S.

Wrought iron (sheet iron); Production of transparent and opaque enamels on — by means of layers of fine gold or silver foil. Fix und Schmidt. G.P. 319,207, 12.3.19.

SHEET iron is first given a preliminary coat of enamel, which is burnt on. An intermediate coating of powdered silver and an easily flowing flux mixed with a volatile oil is then applied, and, after drying, burnt on and polished. This serves as a carrier for the final layer of ordinary enamel on which the gold or silver foil is laid. The process is applicable to articles of jewellery and to the panelling of furniture.—A. R. P.

Furnaces for melting glass or other fusible substances; Oil-fired —. A. A. Mohr. E.P. 143,094, 11.7.19.

Enamels and enamelling. C. Musiol. E.P. 142,688, 6.6.19.

See U.S.P. 1,332,058 of 1920; J., 1920, 297 A.

IX.—BUILDING MATERIALS.

Concrete aggregate; Testing clays for —. D. H. Fuller. J. Amer. Ceram. Soc., 1920, 3, 256–258.

THE most feasible method of burning clay for the production of a light aggregate for concrete consists in firing it rapidly in a rotary kiln under strongly reducing conditions. To test the suitability of a clay for use in the preparation of such an aggregate, it is ground, pugged so as to develop maximum plasticity, and moulded into 2-in. cubes, which are dried and heated to 1375° C. in 360 mins., specimens being withdrawn from the kiln every half hour. Upon the appearance of marked fusion the firing is stopped, the kiln allowed to cool, and the specimens examined as to structure, and the apparent density determined. Products which fail to float in a salt solution of sp. gr. 1.1 or which consist of a shell of dense, vitrified clay enclosing large cavities are unsuitable for use as concrete aggregate.—A. B. S.

PATENTS.

Cement. D. W. Adamson. U.S.P. 1,338,117, 27.4.20. Appl., 25.7.19.

A CEMENT made of calcined, comminuted gypsum and calcined alunite.—A. B. S.

Fireproofing wood. H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,339,488, 11.5.20. Appl., 23.1.19.

WOOD is impregnated with an aqueous solution of a borate containing excess of alkali and then with a solution capable of reacting with the first solution with precipitation of an insoluble borate.
—D. F. T.

Calcining furnace for lime, dolomite, etc.; Annular —. E. Skuballa. G.P. 314,584, 31.8.17.

IN a furnace with a central gas producer, a single opening is provided in each chamber for admission of gas and air and for discharge of exhaust gas. A rotary device enables one or other of the three conducting pipes to be brought into communication with the opening. Air or gas may be supplied to any chamber as required by an arrangement of rotating valves.—W. J. W.

Lime, dolomite, magnesite, cement, etc.; Process and plant for calcining —. A. Heimsoth. G.P. 317,832, 8.6.17.

IN a furnace with two calcining shafts, and either one or two cooling shafts below the calcining shafts, the heating gases are preheated by passing them down through the hot calcined material in one calcining shaft and are then passed upward through the material in the other calcining shaft, together with air which has been preheated by passing it upward through the cooling shaft or shafts.—W. J. W.

X.—METALS; MÉTALLURGY, INCLUDING ELECTRO-MÉTALLURGY.

Case hardening; Industrial control of depth of —. J. Galibourg and M. Ballay. Rev. Mét., 1920, 17, 216–221.

TO estimate the depth of the case, a specimen after fracture is etched, without polishing, with an alcoholic acid copper chloride reagent. The core and case are attacked differently. The ferrite of the core is coated with copper, whilst the martensite of the case remains almost unaffected, giving a sharp line of demarcation between core and case, which is visible to the eye, so that the depth of the case can be estimated accurately to 0.1 mm.

—J. W. D.

Chrome-nickel steel for aeroplane shafts; Production of —. E. Kothny. Stahl u. Eisen, 1920, 40, 677—684. (Cf. J., 1920, 299a.)

A SERIES of experiments on the production under working conditions of an electro chrome-nickel steel (C 0.20, Mn 0.4—0.6, Si 0.2—0.3, Cr 1.0—1.5, Ni 4.0—4.5%) gave the following general results. In order to obtain in the finished steel the necessary fibrous structure only the purest materials must be used, and the bath must be worked with two oxidising slags. A long period of solidification either by cooling in a preheated iron mould or by casting in a sand mould is disadvantageous, resulting in the production of a steel with a well developed transverse structure on fracture in its worked condition. A manganese content of over 0.8% develops a granular structure in the treated steel.—J. W. D.

Ferro-molybdenum; Production of — at Orillia, Ont., and notes on molybdenum. B. C. Lamble. Trans. Canad. Min. Inst., 1919, 22, 61—67.

A FURNACE for the production of ferromolybdenum from molybdenum oxide or sulphide, consisted of a wrought iron jacket fitted on to a cast iron base, connected with one terminal of the electric supply. A cubical crucible, with a taphole arranged at the bottom, was built up inside the iron jacket by means of carbon blocks, the space between the walls of the crucible and the jacket being filled with magnesia bricks. The second electrode consisted of a 10 in. graphite rod held by a water-cooled head over the centre of the furnace. The power used was 4000 amp. at 55 volts. By direct reduction of a mixture of 70% of molybdenite concentrates and 30% of iron pyrites by coke in the presence of lime and silica as fluxes, 100 tons of ferro alloy assaying 71% Mo, 3.66% C, 0.08% S, 0.03% P, 1.35% Si, and 23.8% Fe has been produced, 80% of the total molybdenum in the charge being recovered in the alloy with a power consumption of 6—7 kw.-hrs. per lb. of alloy. The remainder of the molybdenum was recovered as dust or by wet dressing the slag.—A. R. P.

Aluminium alloys [duralumin]; Quenching of certain —. L. Guillet, J. Durand, and J. Galibourg. Rev. Mét., 1920, 17, 202—215.

A DETAILED account of an investigation of which the results have been published previously (J., 1919, 776a).

Nickel plating of aluminium and its alloys. L. Guillet and M. Gasnier. Comptes rend., 1920, 170, 1253—1256.

THE surface of the aluminium is prepared by subjecting it to a sand blast applied under a pressure of 1500 g. per sq. cm.; the sand used should pass through a 0.2 mm. sieve. Using an ordinary nickel plating bath, if the deposit of nickel does not exceed 0.01 mm. it is quite satisfactory, when tested by stamping, folding, or burnishing. If coarser sand or a lower pressure is used the deposit is not so satisfactory. If a thicker deposit is required it is better first to plate with nickel to a depth of 0.006 mm., then apply to this a deposit of copper, 0.02 mm. thick, and then a further coating of nickel.—W. G.

Zinc; Theoretical principles underlying the metallurgy of —. E. Jänecke. Metall u. Erz, 1919, 16, 247—251.

IF solid zinc oxide and carbon be added to molten zinc in a space from which the air has been exhausted, then at temperatures above the melting point of zinc an equilibrium will be established between the two solid phases and one liquid phase mentioned and a gaseous phase. It is a univariant equilibrium, since the four phases may be formed

from three independent components, and hence the pressure and composition of the gas will be constant at a definite temperature and will vary with the temperature. In applying the results of a theoretical discussion of the process to the technical process regard must be paid to the slowness of the reaction between two solid substances which, even at high temperatures, have only a small vapour pressure. By increasing the velocity of the reaction improvements in the smelting process might be effected.

Mercury; Determination of —. C. M. Bouton and L. H. Duschak. U.S. Bureau of Mines, Tech. Paper 227, 1920, 44pp.

ONE grm. of the finely powdered ore is mixed with 0.5 g. of dry calcium oxide and introduced into a glass tube (22 cm. long and not exceeding 10 mm. external diameter) in which has previously been placed a short layer of coarse sand. The ore is covered with a 1 cm. layer of lime, and then with coarse sand, and the whole kept in position by a brass wire gauze plug. The tube is heated in a furnace at 500° C., with the open end projecting about 8 to 12 cm., for 15 mins., and then placed, open end downwards, in 5 c.c. of hot nitric acid. If much sulphur is present cupric oxide is added to the lime (2:1), whilst if organic matter is also present 0.1—0.3 g. of powdered potassium chlorate is mixed with the coarse sand used for filling the end of the tube. The mercury dissolved by the nitric acid is oxidised by potassium permanganate, the excess of which is destroyed by hydrogen peroxide, and the solution (not exceeding 30 c.c.) treated with 2 c.c. of 10% ferric sulphate or nitrate solution (free from halides) and titrated with potassium thiocyanate solution. Mercury in solution is best determined by precipitation with hydrogen sulphide and treatment of the precipitate as described above.—C. A. M.

Tin; Electrolytic estimation of — in tetrachloride. Revision of the atomic weight of tin. G. P. Baxter and H. W. Starkweather. J. Amer. Chem. Soc., 1920, 42, 905—917.

THE atomic weight of tin has been determined by the electrolysis of solutions of carefully purified stannic chloride in 0.3N hydrochloric acid in a cell provided with a mercury cathode, the tin being weighed as tin amalgam. The value 118.703 is found as a mean of 16 experiments.—J. F. S.

PATENTS.

Steel; Refining of —. R. A. Hadfield. E.P. 142,885, 14.11.18.

A PARTLY refined normally finished basic carbon steel or a partly refined normally finished basic nickel-chromium steel is subjected to a melting and refining treatment in an electric furnace in the presence of two successive slags, one comprising lime and iron oxide, and the second composed of lime, fluorspar, and ferrosilicon.—J. W. D.

Iron-ore smelting furnace; Electric —. J. D. Shipton. U.S.P. 1,338,103, 27.4.20. Appl., 22.9.19.

THE furnace comprises a series of electrical smelting chambers disposed around a central mixing chamber, with means for delivering ore separately to each smelting chamber. The molten metal is tapped from each smelting chamber, delivered to the mixing chamber, and tapped from the latter.—B. N.

Iron and steel; Manufacture of —. H. Lang. U.S.P. 1,340,548, 18.5.20. Appl., 7.7.19.

FINELY ground iron ore and a reducing agent are gradually heated in closed iron containers to a reducing temperature and the containers are then

transferred to a melting furnace without bringing them into contact with an oxidising agent.

—J. W. D.

Iron and steel objects; Process and apparatus for coating — with white metal. K. Haas. G.P. 302,440, 2.12.14.

THE metal to be coated is cleaned by treatment with a reducing flux which also dissolves oxides, and then, in the absence of air, immediately brought in contact with the coating metal at a temperature above its melting point and that of the flux. Suitable fluxes are boric or phosphoric acids or their salts, or, for lead and tin, a mixture of lead or stannous chloride respectively, with zinc and ammonium chlorides.—A. R. P.

Iron articles; Process for producing a rust-proof coating of phosphate on —. H. Arnold. G.P. 305,677, 17.9.16.

THE articles are treated with a highly concentrated solution of phosphoric acid or phosphate of a definite degree of acidity, which may be produced by the addition of sulphuric or other acid to the solution.—A. R. P.

High-speed steel; Manufacture of —. M. Bormann. G.P. 310,042, 7.11.15. Conv., 19.4.15.

THE steel contains 7—12% Cr in place of the usual tungsten content, and 1—2% of one or more of the following: boron, molybdenum, vanadium, titanium, cobalt, tungsten. In order to obtain a good cutting edge, the steel is allowed to cool and then reheated one or more times during the forging. The heat treatment consists in heating to 50°—100° C. above the hardening temperature (700°—800° C.), quenching in water at 18° C., then hardening at the correct temperature.

—A. R. P.

Ore; Apparatus for desulphurising and treating —. B. Q. P. Foss, Assr. to The Foss International Ore Reduction Co. U.S.P. 1,338,292, 27.4.20. Appl., 22.7.14.

THE ore is quickly heated to a temperature sufficient to dry it and remove volatile constituents, and is maintained in motion during the heating. Refrigerated fluid is applied to the ore immediately after heating to reduce it to a friable state.—B. N.

Platinum substitute in electrical terminals, etc.; Composition of matter [alloy] for —. F. A. Fahrenwald, Assr. to The Rhotanium Co. U.S.P. 1,339,505, 11.5.20. Appl., 18.2.18.

THE alloy consists largely of gold and palladium having a melting point above 1150° C. and hardness at least twice that of gold.—B. M. V.

Metal alloy. G. C. Deeter. U.S.P. 1,340,437, 18.5.20. Appl., 18.6.19.

AS alloy containing as its principal constituents Pb 90, and As 5%.—J. W. D.

Alloy. T. Koch, Assr. to American Platinum Works. U.S.P. 1,340,451, 18.5.20. Appl., 24.8.18.

AS alloy containing not less than 75% Au, 0.25—5.0% Mn, and 24.75—3.3% Ni.—J. W. D.

Open-hearth furnace. F. B. McKune. U.S.P. 1,339,855, 11.5.20. Appl., 27.10.19.

THE furnace has a gas port at each end, and air is supplied through passages leading both direct to the gas ports and to the top of the furnace at each end, the latter passages being controlled by dampers.—B. M. V.

Electrolytic process. [Depositing copper from impure solutions.] W. E. Greenawalt. U.S.P. 1,340,826, 18.5.20. Appl., 19.3.15.

IN the electrolysis of impure copper solutions,

copper sulphide is precipitated by hydrogen sulphide and the copper sulphide applied to the electrolyte as a reducing agent.—B. N.

Basic slag with high phosphorus content; Method of obtaining —. B. Quehing. G.P. 318,147, 25.2.16. Addn. to G.P. 301,839.

A basic slag, rich in citrate-soluble phosphate, may be obtained by adding lime, mixed with oxides of iron or manganese, in the form of briquettes, to the furnace charge. The melting point of the briquettes is about 1010°—1030° C.—W. J. W.

Tin alloys; Electrolytic refining of —. Siemens und Halske A.-G. G.P. 319,384, 27.3.17.

THE formation of gelatinous stannic acid may be avoided by adding colloids such as tannin, indigo, and alizarin to the electrolyte. The addition of phosphoric acid to the electrolyte, and agitation with air, are advantageous.—W. J. W.

Furnaces for heating metal articles. Aktiebolaget Svenska Kullagerfabriken. E.P. 124,427, 4.3.19. Conv., 4.3.18.

Furnaces for heat treatment of metal articles [in an atmosphere of coal gas]. H. J. Yates and S. N. and E. R. Brayshaw. E.P. 142,671, 21.5.19.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Electrolysing liquids; Apparatus for —. J. S. Withers. From National Electro-Products, Ltd. E.P. 143,082, 26.6.19.

A BI-POLAR electrode comprises a plate of non-conducting material having a gas chamber, with open bottom, formed at the top of each side of the plate, and a series of electrode members formed of wire located at each side of the plate below the chambers, and spaced from the plate by hollow vertical ribs provided with holes for the passage of electrolyte. The upper ends of the spaces communicate with the gas chambers. A sheath of porous material is fitted over the electrode embracing the opposite faces, whereby gas and electrolyte spaces are formed communicating with the chambers.—B. N.

Electric insulation. Elektro-Material G. m. b. H. E.P. 143,280, 12.7.18. Conv., 11.4.18.

THE insulating fabric is impregnated with a solution of a cellulose derivative such as cellulose acetate, nitrocellulose, cellulose formate, and the like. When employed for insulation purposes, the impregnated fabric is moistened with a solvent while in position, in order to effect adherence to the material to be insulated.—J. S. G. T.

Electrical accumulators. C. H. Worsnop. E.P. 143,327, 24.2.19.

PLATES for use in accumulators of the "alkaline" or iron and nickel type are produced by electrolytically depositing an alloy of iron, cadmium, tin, and titanium upon an iron plate for the negative electrode, and an alloy of nickel, cadmium, tin, and titanium upon a nickel plate for the positive electrode. At intervals the plates are removed from the electrolytic bath and dusted with graphite, then subjected to further treatment in the electrolytic bath until of the desired thickness. The plates may be used as produced or the deposited layers of alloy with intervening graphite layers may be stripped from their cores, and either bound together in a metal frame or pressed between sheets of metal gauze.—J. S. G. T.

Resistance element; Electrical-heater —. W. E. Gardner, Assr. to H. C. Black and J. Jacob. U.S.P. 1,338,294, 27.4.20. Appl., 7.7.19.

AN electrical resistance element consists of an intimate mixture of finely-divided carbon and bone ash.—B. N.

Electrical process and apparatus for compounding liquids with gases or other components and the products thereof, including carbonating beverages. J. E. Bloom. U.S.P. 1,338,352, 27.4.20. Appl., 30.9.19.

THE liquid components are separately electrified, with opposite signs and different potentials, and then mixed. The process is repeated with the mixed product and a third gaseous component, all the actions being carried out under insulated conditions.—B. N.

Electric furnace. J. Herlenius, Assr. to Hamilton and Hansell, Inc. U.S.P. 1,338,631, 27.4.20. Appl., 8.2.18.

AN electrode projects through an aperture in the side wall into the furnace, and is fixed to a pivotal support on the outside of the furnace shell. The electrode is surrounded by a flat packing ring substantially in the plane of the pivotal axis of the support, thus preventing leakage of air into the furnace chamber through the opening in the side wall.—B. N.

Electric furnace. J. Hughes; E. W. Hughes, admtrix. U.S.P. 1,339,393, 11.5.20. Appl., 11.10.19.

THE metal shell of the furnace is provided with an inner refractory lining, the outer surface of which has an offset so that a gap is formed between the inner surface of the shell and the outer face of the refractory lining. A foraminous filler between the shell and refractory lining prevents warping and distortion of the lining and shell, whilst closing the gap without preventing circulation of a cooling medium through it.—B. N.

Electric furnace; Method of operating an —. M. R. Trembour, Assr. to Ludlum Electric Furnace Corp. U.S.P. 1,339,428, 11.5.20. Appl., 24.3.16.

AN electric current is passed through the charge

between an electrode adjusted to form an arc with the charge and an electrode of carbonaceous material adjusted to contact with the charge, the electric current being used both to supply heat at the arcing electrode as well as to prevent carbonisation of the charge and dissolution of the contacting electrode.—A. G.

Electric furnace; Process of controlling the thickness of walls in an —. C. H. Chapman, Assr. to General Abrasive Co., Inc. U.S.P. 1,340,155, 18.5.20. Appl., 20.2.17.

THE furnace walls are constructed by first melting and then cooling a portion of the charge, whereby the cooled portion forms a solid, continuous, homogeneous, crystalline, heat-resisting wall about the central portion of the furnace, providing a receptacle for the molten mass.—B. N.

Electrodes for soldering and depositing metals by the electric arc. E. H. Jones. U.S.P. 1,339,515, 11.5.20. Appl., 18.2.20.

AN electrode is formed by moistening a rod coated with silica, and applying a slag-forming powder to the moist silica.—B. N.

Electrodes for soldering and depositing metals by the electric arc. E. H. Jones, and Alloy Welding Processes, Ltd. E.P. 142,934, 14.2.19.

XII.—FATS; OILS; WAXES.

Salmon oil. H. A. Gardner. Circ. 92, Paint Manufacturers' Assoc., U.S.A. May, 1920.

OIL from the king salmon had the following characters: Sp. gr. 0.9268; $n_D^{25} = 1.4788$; acid value, 9.8; saponif. value, 183; and iodine value, 159. The raw oil was tacky after 3 days' exposure, but with 10% drier gave a fairly firm film. Oil from the silver salmon had: Sp. gr. 0.9183; $n_D = 1.4753$; solidif. pt. -3° to -11° C.; saponif. value, 193.3; acetyl value, 17.83; insol. fatty acids, 92.59%; unsaponif. matter, 1.69%; iodine value, 150.6; solidif. pt. of fatty acids, $29-2^\circ$ C.; and hexabromide 45.03%. Mixed with a suitable drier it dries well in 18 hrs., especially when blown.

—C. A. M.

Channel cat fish oil. H. A. Gardner. Circ. 93, Paint Manufacturers' Assoc., U.S.A. May, 1920.

A SAMPLE of channel cat fish oil had: Sp. gr. 0.9231; $n_D^{20}=1.4741$; acid value, 10.9; saponif. value, 192; and iodine value, 123. It is unsuitable for paints or varnishes in the raw state, but dries better after heat treatment.—C. A. M.

Ceryl alcohol and cerotic acid of Chinese wax. A. Gascard. Comptes rend., 1920, 170, 1326—1328.

CHINESE wax consists for the most part of ceryl cerotate. Brodie's formulae for ceryl alcohol $C_{21}H_{43}OH$ and for cerotic acid $C_{26}H_{53}CO_2H$ are confirmed.—W. G.

Boiling oils. Gardner and Parks. See XIII.

PATENTS.

Catalyst [for hydrogenation of oils]; Production of —. W. P. Schuck. E.P. 142,576, 18.2.19.

A SOLUTION, containing 0.1716 g. of nickel nitrate and 0.25 g. of sugar per c.c., is passed in a state of suspension in an inert gas through a muffle, heated to 550°—650° C. The water is vaporised and the nickel nitrate is decomposed and forms a "black, flaky, non-oxidisable powder" which is removed from the muffle while still in a state of suspension in the gas. The product contains the catalytic metal but no free carbon (cf. U.S.P. 1,305,173; J., 1919, 589A).—W. H. C.

Fish oil; Process for removing the odour from —. U. Ioka. U.S.P. 1,340,050, 11.5.20. Appl., 10.2.19.

THE oil is mixed with cypress and cedar sawdusts and green cedar leaves, the mixture heated, cooled, and filtered, and the filtered oil exposed to sunlight.—C. A. M.

Bile; Purification of — [for use as detergent]. K. Horkenbach. G.P. 317,721, 14.9.17.

THE bile, after standing to separate mucilaginous substances, is subjected to osmosis either after treatment with acids and alkalis, or concomitantly therewith. Electro-osmosis may, if desired, be substituted for simple dialysis.—G. F. M.

XIII.—PAINTS; PIGMENTS; VARNISHES ; RESINS.

Paint: a plastic material and not a viscous liquid: the measurement of its mobility and yield value. E. C. Bingham and H. Green. Proc. Amer. Soc. for Testing Materials, 1919, 19, 640—661.

Viscous liquids will start to flow no matter how small a pressure be applied, whereas with plastic materials no flow takes place until the pressure has exceeded a certain definite value to which the name "yield value" is given. When pressures are plotted as abscissæ and volumes of flow per unit time as ordinates, the curve of a true liquid is linear and passes through the origin, whilst in plastic solids the "yield value" appears as the intercept of the linear curve on the pressure axis. For plastic solids, Poiseuille's equation requires modification to $\mu = KV/(P-f)$, where μ is the mobility (corresponding to the fluidity of liquids), V is the volume of flow in unit time, P is the pressure, and f is the yield value. Paint behaves as a plastic solid in that it will maintain a vertical surface provided the weight is not too great to exceed the yield value. A "plastometer" has been devised which permits of the determination of flow of a plastic solid through a capillary in unit time with varying pressure, whereby both its mobility and its yield value can be measured. The apparatus, for the mechanical details of which the

original paper must be consulted, comprises a pressure tank, a pressure regulator and stabiliser, a manometer, and a container for holding the paint under examination. This container is a form of viscometer of the efflux type wherein the whole unit together with the receiver may be kept at constant temperature. The volume of flow is determined by reference to the density of the paint and the weight of the drops, the latter being constant at a constant rate of falling from the end of the capillary. Readings obtained from the examination of three typical paints in the plastometer are as follows:—

Pigment base of paint.	μ .	f.
Zinc oxide	0.204	87
Leaded zinc	0.373	320
White lead	0.171	117

The "thinning down" of paints on storage is stated to be a function not of change of mobility but of fall in yield value.—A. do W.

Oils; Fume loss in boiling —. H. A. Gardner and H. Parks. Circ. 95, Paint Manufacturers' Assoc., U.S.A. May, 1920.

THE losses on heating linseed, boiled linseed, menhaden, soya bean, perilla, and sunflower oils for 2—4 hrs. at 500° F. (260° C.) and 550° F. (about 290° C.) in a small open metal pan are given in tables together with the corresponding sp. gr. Linseed oil lost 2% after 2 hrs. and 2.9% after 4 hrs. at 500° F., and 3.9% after 2 hrs. and 8.6% after 4 hrs. at 550° F.—C. A. M.

Salmon oil. Channel cat fish oil. Gardner. See XII.

PATENT.

Anti-fouling paint for ships' bottoms and process for the manufacture of same. E. Ariò. E.P. 131,601, 21.8.19. Conv., 23.5.14.

THE effectiveness of anti-fouling paints containing inorganic or organic poisons is increased by incorporating in the paint fatty acids (or the corresponding sodium salts) of the series $C_nH_{2n}O$, ranging from 4 to 14 atoms of carbon.—D. F. T.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Rubber compounds. N. D. Nielsen. E.P. 127,821, 2.6.19. Conv., 31.5.18.

RUBBER is mixed with a suitable quantity of tough, durable, flexible and resilient organic matter in the form of thin rough flakes, such as fish scales, whereby the rubber material is greatly improved in durability and toughness.—D. F. T.

Rubber; Utilisation of bark shavings from rubber trees, and extraction of — from such bark shavings. R. T. Smith. From A. H. Claessen. E.P. 142,946, 20.2.19.

THE bark shavings are ground and masticated between heated rollers, preferably at a temperature near 275° F. (135° C.), so as to convert the whole into a dough-like mass. This may then be mixed with a vulcanising agent and, after shaping or moulding, vulcanised. Alternatively the mass may be passed through a scrap-washer and the separated rubber crépé; a larger yield of rubber is then obtained than is possible by the customary procedure.—D. F. T.

Rubber waste; Apparatus for reclaiming —. F. L. Kryder and E. W. Snyder. U.S.P. 1,310,776, 18.5.20. Appl., 8.3.18.

The reclaiming chamber consists of a rotary steam-

jacketed drum with horizontal axis; the axles at each end are tubular, one permitting the introduction of steam into the jacket whilst through the other there passes an inlet pipe reaching to the interior of the chamber and serving to introduce a solution for treatment of the rubber; the solution is forced in under pressure by means of a pump, thus increasing the pressure within the reclaiming chamber without substantially raising its temperature.—D. F. T.

Rubber waste; Process of reclaiming and regenerating —. F. L. Kryder. U.S.P. 1,340,777, 18.5.20. Appl., 18.8.19.

RUBBER waste is disintegrated, heated with an aqueous solution containing 10–15% of sodium hydroxide for 6–20 hrs. at a pressure between 50 and 200 lb. per sq. in., and then subjected to the action of a solvent comprising phenylenediamine (1 pt.), paraffin oil (2 pts.), mineral rubber (2 pts.), rubber resin (1 pt.), and acetic acid (2 pts.). The resulting mass is washed and dried.—D. F. T.

Waterproofing fabrics. E.P. 129,630. See V.

Artificial leather. U.S.P. 1,337,802. See XV.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning materials; The "shake" method and the "filter bell" method in the analysis of — with hide powder. G. Baldracco and S. Camilla. J. Soc. Leather Trades' Chem., 1919, 3, 110–123.

THREE sensitive tests for gallic acid and protocatechuic acid in the non-tan solution obtained in the analysis of tanning materials are given. On adding three drops of a 0.5% solution of ferric chloride to the non-tan solution, gallic acid gives a blue and protocatechuic acid a green coloration. On adding three drops of a 2% solution of ammoniacal nickel sulphate to the non-tan solution, shaking, boiling, and adding excess of ammonia, gallic acid gives a red coloration at first, turning to brown, and protocatechuic acid a reddish-brown. On adding three drops of 4% solution of formaldehyde to the non-tan solution and then a few drops of concentrated sulphuric acid, gallic acid gives a reddish colour, and a rose-coloured precipitate forms after standing for 1 hr.; protocatechuic acid gives a violet ring surmounted by a milky layer. On submitting the non-tans from the "filter bell" method of analysis to these tests negative results were always obtained, thus proving that gallic and protocatechuic acids, though non-tanning substances, have been completely absorbed by the hide powder. Positive results are always obtained on testing the non-tans from the "shake" method of analysis. Greater efficiency is claimed for a modified "shake" method (J., 1920, 123A).

—D. W.

Tannin; Titration and estimation of — with iodine. F. T. Lee. J. Soc. Leather Trades' Chem., 1919, 3, 8–10.

FIVE c.c. of filtered tannin solution, containing not more than 1 g. of pure tannin per l., is oxidised with 25 c.c. of N/50 iodine solution for 20 mins. in a stoppered bottle, and the excess of iodine titrated with N/50 thiosulphate, using starch as an internal indicator. Six c.c. of the non-tannin solution obtained in the official S.L.T.C. method of tannin analysis is similarly titrated to determine the iodine absorbed by the non-tannins. The iodine solution must be standardised against 5 c.c. of a 0.1% solution of pure gallic acid to obtain the gallic acid equivalent in terms of which the other titrations are all calculated and expressed as outlined by Procter ("Leather Chemists' Pocket

Book," p. 107). The method is designed for comparative control purposes.—D. W.

Mangrove [tannin]; Detection of — in mixed tannin extracts. E. Schell. J. Soc. Leather Trades' Chem., 1918, 2, 284–286.

A REVIEW of the several methods suggested for the detection of mangrove tannin in tanning extracts. The solubility of mangrove tannin in ethyl acetate is a very uncertain guide. The amount of chlorine or lime in the ash is also a doubtful indication of the presence of mangrove, since these constituents may have been introduced by using hard water. The Mulhouse dyeing test with mordanted cotton is unreliable. The precipitates obtained in the Schell test, in which a cobalt solution is added to a solution of the tanning extract, are not sufficiently well defined in colour to render it an efficient test. It can only be employed with normal extracts, and fails with solubilised extracts, and with those which have been subjected to a treatment with alkaline compounds and which give an alkaline reaction in solution.—D. W.

Tannins of galls, sumach, myrobalans, divi-divi, and quebracho; Relative affinity for cotton and mordanting value of the —. R. H. Wisdom. J. Amer. Leather Chem. Assoc., 1919, 14, 6–9.

THE affinity of tanning materials for cotton does not bear any simple relation to their tannin content. The percentage of total solid matter absorbed by the cotton was determined for each material, and is termed the "absorption value." The mordanted cotton was washed, passed through an iron solution, incinerated, and the amount of iron fixed was determined. The percentage of iron fixed by each part of absorbed matter was multiplied by the "absorption value" and yielded the following "mordant values": Galls 135, sumach 118, myrobalans 98, divi-divi 80, quebracho 66. The actual colour depths on cotton agreed with these figures. This method is suggested for comparing the relative mordanting values of these and other materials in dyeing leather, since galls and sumach are the best mordants for leather, and myrobalans is the next in order.—D. W.

Degree of tannage in different stages of process. O. Riethof. J. Amer. Leather Chem. Assoc., 1919, 14, 20–22.

SAMPLES of leather cut from the backbone of the hide about two feet from the tail during various stages of the sole leather and belting leather tanning processes were dried and analysed. The leather was found to be half tanned in 27 days, and three-fourths to four-fifths tanned in half the time necessary for completion of the tannage (100–108 days). The assumption that the stock in process is, on the average, only half tanned is thus proved to be a serious under-estimate.—D. W.

Chrome [tanning] liquors; Statement of basicity of —. J. R. Blockey. J. Soc. Leather Trades' Chem., 1919, 3, 11–13.

It is suggested that the basicity should be stated as the number of hydroxyl groups attached to two atoms of chromium. The variation would then be between 0 and 6. Such an expression of the basicity is determined by the formula:—

$$6 - \left(\frac{152}{\text{Amount of Cr}_2\text{O}_3} \times \frac{\text{c.c. N/1 NaOH}}{1000} \right)$$

—D. W.

Chrome leather problems for research laboratories. E. J. White. J. Amer. Leather Chem. Assoc., 1919, 14, 2–5.

IN the neutralisation of chrome-tanned leather the absorption of the alkali may be due to neutralisation of the acid introduced from the tanning baths,

to combination of alkali with the hide substance, and to adsorption. The amount of alkali used in neutralising acidity could be ascertained by determining the sodium salts (thiosulphate and sulphate) in the residual liquors. In the initial stage of neutralisation the proportion is about 75% thiosulphate and 25% sulphate, indicating a tannage by 3 pts. of basic chromium thiosulphate and 1 pt. of basic chromium sulphate. Other problems on tanning include a study of the boiling test before and after neutralisation, and the presence or absence of acid in the essential tanning agent. The dyeing and fat liquoring of chrome-tanned leathers can be studied by the analysis of the residual liquors for sulphate and thiosulphate. The absorption of chromic acid from various mixtures by the skin, and the preferential absorption by the skin of different acids, both require further study.

—D. W.

Animal hides; Coloration of — by means of o-vanillin and o-protocatechuic aldehyde and tanning with aldehyde. O. Gerngross. *Z. angew. Chem.*, 1920, 33, 136—138.

DECOMPOSITION products of proteins (glycylglycine ester and tyrosine ester) give the same colorations with Schiff's o-protocatechuic aldehyde base as those produced in hides by o-protocatechuic aldehyde and o-vanillin. Formaldehyde-tanned leather does not give the same colorations as ordinary leather with these reagents, but reacts like ordinary leather with a solution of sodium diazobenzene-sulphonate, giving a blood-red coloration. This indicates that the imino group of the iminazole ring of histidine in formaldehyde-tanned leather has not been replaced by formaldehyde, and that no envelopment of the fibres by polymeric compounds of formaldehyde has occurred. The tanning properties of o-protocatechuic aldehyde are due not to an aldehyde, but to a dihydroxy group.

—C. A. M.

Gelatin; Kjeldahl's method for the determination of nitrogen as applied to —. H. G. Bennett and N. L. Holmes. *J. Soc. Leather Trades' Chem.*, 1919, 3, 24—27.

The digestion of gelatin in the Kjeldahl method differs from that of leather in the small amount of carbonaceous matter to be oxidised. The clearing of the liquor is no criterion of complete hydrolysis. Experiments with and without accelerators and with various periods of digestion ranging from 1 to 6 hrs. showed that sulphuric acid alone does not give correct results. The most reliable figures are obtained by heating 0.25 g. of gelatin, cut into small pieces, in a 250 c.c. flask with 10 c.c. of concentrated sulphuric acid until it is completely dissolved. The liquid is cooled, and 10 g. of pure anhydrous potassium sulphate is added, and the boiling continued for 4—6 hours, after which the ammonia formed is distilled.—D. W.

Chromic chloride solutions. Baldwin. See VII.

PATENTS.

Artificial leather. A. A. Somerville, Assr. to New York Belting and Packing Co. U.S.P. 1,337,802, 20.4.20. Appl., 15.1.18.

A VULCANISED rubber layer and a sheet of paper are wound up into a roll, subjected to the action of a vulcanising medium, and the sheet of paper removed. The material has the appearance, texture, flexibility, and general characteristics of dull finished leather.—D. W.

Artificial leather and similar products; Manufacture of —. E. Reidel. G.P. 302,445, 8.5.15.

DRIED animal intestines, sinews, and the like are plumped, e.g., with acetic acid or sodium sulphide, washed, compressed between rollers, dried, and

saturated with a solution of albumin and a marine animal oil. The product, after compression to sheets, is dried and tanned by the combined mineral and vegetable process.—L. A. C.

Tanning [; Degreasing hides and skins preparatory to—]. Degreasing apparatus. C. C. Krouse. U.S.P. (A) 1,338,307 and (B) 1,338,308, 27.4.20. Appl., 20.6.19 and 27.1.20.

(A) Raw hides and skins containing a high percentage of fat are treated before tanning with sufficient grease solvent to dissolve the grease, which is carried away on removal of the solvent. (B) The apparatus comprises a closed tank having a closure at one side. In the tank are parallel, hollow, spaced elements to which heating fluid is supplied, guides between the heating elements, and reticulated frames to which the hides and skins are clamped. Means for the supply and withdrawal of liquid and for producing a vacuum are connected to the tank.

—D. W.

Shark-skins and the like; Treating — preparatory to tanning. A. Rogers, Assr. to the Ocean Leather Co. U.S.P. 1,338,531, 27.4.20. Appl., 8.5.19.

THE dermal armouring of shark-skins and the like is removed by subjecting them to the action of heated fluid. The epithelium layer from the flayed skins is removed with a mixture of 5 parts of lime and 1 part of sodium sulphide.—D. W.

Glue; Manufacture of water-resistant —. H. Grünwald. G.P. 317,963, 9.7.18.

ANIMAL glue is treated with a product obtained by the interaction of albumin and formaldehyde. When the glue is used the action of heat and pressure causes the liberation of formaldehyde, which acts on the glue and renders it insoluble.—W. J. W.

Mocha leather; Manufacture of —. L. Forse, Assr. to S. T. Thring and R. J. Luffman. U.S.P. 1,339,751, 11.5.20. Appl., 29.12.16.

XVI.—SOILS; FERTILISERS.

Calcium sulphate; Effect of — on the solubility of soils. M. M. McCool and C. E. Millar. *J. Agric. Res.*, 1920, 19, 47—54.

FROM field observations in Michigan it was considered that calcium sulphate was a soil stimulant. Laboratory experiments were made with sand and loam soils, which were allowed to stand in contact with excess of calcium sulphate solution for 24 hours, and then dried, transferred to containers, and made up to a low and a high water content. The samples were examined every few days for a month by the freezing-point method for the formation of soluble salts. The treatment was found to have increased the solubility of the soil considerably. When the soils were well washed after the calcium sulphate treatment the increase in solubility was even greater. Thus the calcium sulphate had effected some change in the soils, leading to the formation of soluble compounds. Calcium phosphate alone decreased the solubility of the soil, and in combination with calcium sulphate neutralised much of the effect of the latter. The carbon dioxide formed by the soils during the experiments was rather less than in untreated soil, so that the action of calcium sulphate was not due to any bacterial activity.—J. H. J.

Germination of seeds and growth of seedlings; Effect of reaction of solution on —. R. M. Salter and T. C. McIlvaine. *J. Agric. Res.*, 1920, 19, 73—95.

SEEDS of wheat, maize, soya bean, alfalfa (lucerne), and clover were germinated and grown in culture solutions of uniform composition, but with varying hydrogen-ion concentration. It was found best to adjust the reaction by adding a constant amount of phosphoric acid to all the solutions, followed by progressively increasing amounts of caustic soda. The optimum reaction for germination was found to be between $p_H=7.7$ and $p_H=3$, a slightly acid solution being most favourable. The maximum growth of the seedlings occurred between $p_H=5.16$ and $p_H=5.94$. The wheat seedlings tended to adjust the reaction during growth to a point just below neutrality.—J. H. J.

Calcium cyanamide; Physiological action of crude —. Siebner. *Chem.-Zeit.*, 1920, 44, 369—370, 382—383.

A DETAILED review of the literature on the physiological action of crude calcium cyanamide is given. Its injurious action, which is confined chiefly to the skin and to the respiratory organs, is not greater than that of other dusty substances, and can be prevented by the avoidance of dust. Crude calcium cyanamide cannot be called a poison in the ordinary sense of the word, since as much as 40—50 g. has to be taken to produce any poisonous effect. It does, however, produce certain cases of sudden illness, which have been found always to be associated with the consumption of alcohol. Workers with the substance, who were exposed to the inhalation of dust, have been accustomed to partake of alcoholic beverages to remove the irritation, and it is this combination which has brought about "cyanamide disease." Farmers who always work with the substance in the open air are not subject to illness. It is suggested that illness would be prevented in works by the use of drinks free from alcohol, and that even on the land it would be advisable that the substance should be applied with the wind and not against it.—J. H. J.

PATENTS.

Mineral-manure process. W. McA. Johnson. U.S.P. 1,338,734, 4.5.20. Appl., 21.6.18. Renewed 6.2.20.

A MOLTEN slag, containing a potassium compound in solution, is blown into a fine state of subdivision.—W. J. W.

Fertiliser, and manufacture of same. M. Fjellanger, Assr. to Norsk Hydro-Elektrisk Kvaelfstofaktieselskab. U.S.P. 1,340,708, 18.5.20. Appl., 6.2.20.

A FERTILISER consisting of urea nitrate and calcium carbonate.—W. J. W.

Crude calcium cyanamide; Process for decomposing —mixed with a liquid, by means of carbon dioxide. G. Zarniko. G.P. 300,632, 6.7.16.

THE process of incorporating and disintegrating crude calcium cyanamide with a liquid and its treatment with gases may be carried out in a mill with free-moving grinding bodies, or in a drum mill provided with teeth. The operation may be made continuous by introducing the calcium cyanamide and liquid at one end and removing the reaction product containing urea at the other.

—W. J. W.

Superphosphates; Process of manufacturing —. O. Rosenthal. G.P. 315,393, 11.8.14.

DRY phosphorus pentoxide is mixed with dry crude phosphate and sufficient water added to convert the pentoxide into phosphoric acid. The mixture may

be first treated with part of the water only, the remainder being added later. The phosphorus pentoxide may be used direct from the process of manufacture whilst still hot. The reaction is assisted by the heat liberated by the combination of the water with the pentoxide, and is initiated at 100° C.—W. J. W.

Furnace for the manufacture of a germ-free fertiliser from faeces and other organic waste products. Stettiner Chamotte-Fabr. A.-G. vorm. Didier. G.P. 316,148, 13.6.17.

A FURNACE grato is supported on a vertical partition wall between the drying and the sterilising chambers, the length of the grate being slightly less than the length of the chambers, thus leaving an intermediate space. An overhanging arch is erected above the grate, which causes the furnace gases to pass first over the surface and then underneath the grate.—W. J. W.

Boiling and drying organic materials, especially slaughterhouse waste; Process of —. K. Niessen. G.P. (A) 318,542, 12.5.15, (B) 319,335, 21.7.16, and (C) 319,336, 13.5.17. Addns. to G.P. 317,818 (J.), 1920, 379 A).

(A) IN vessels having a single steam-jacket an air-pipe passes through the jacket into the interior of the vessel, the inner opening of the pipe being provided with mechanically operated valves. By this means the steam in the jacket is condensed and the temperature of the vessel gradually lowered. (B) The vessel may be divided into two chambers by a grating, and the air-pipes caused to open into distributing boxes communicating with the lower compartment by means of pipes. In this way the fats and gelatin can be removed during the boiling process and then separated from each other outside the vessel. (C) The pipe for drawing off condensed water from the steam jacket is provided with a cock or similar contrivance so that during boiling or sterilising the water can be run off, whilst it is allowed to accumulate during the drying process. These objects may be also achieved by suitably regulating the size of the condensed water pipe to cope with the amount of water in one case, but not in the other.—W. J. W.

XVIII.—FERMENTATION INDUSTRIES.

Hop bitter acids; Colloid-chemical studies on —. H. Lüers and A. Baumann. *Koll.-Zeits.*, 1920, 26, 202—212.

HUMULONE (a hop bitter acid) exists in aqueous solution and in wort in the form of hydrosol, with a negative charge (*Cf. J.*, 1920, 462a). It is strongly adsorbed by charcoal from aqueous solution, and its power of producing a stable foam is in keeping with its power of reducing the surface tension and its adsorption. (*Cf. J.C.S.*, July.)

—J. F. S.

Chloropicrin; Action of — on yeast and on the flora of wine. G. Bertrand and Rosenblatt. *Comptes rend.*, 1920, 170, 1350—1352.

CHLOROPICRIN at a concentration of 5—6 mg. per l. entirely arrested fermentation due to yeast (a bottom fermentation yeast from a Champagnewine), but did not kill the yeast cells. In order to kill

the yeast, by an exposure for 24 hrs. at 27° C., a concentration of 30—40 mg. per l. was necessary. A concentration of 1—2 mg. per l. was sufficient entirely to prevent the development of *Saccharomyces vini*.—W. G.

Pentose-destroying bacteria; Fermentation characteristics of —. E. B. Fred. W. H. Peterson, and A. Davenport. *J. Biol. Chem.*, 1920, 42, 175—189.

THE action of organisms on a large number of substances of a carbohydrate nature and on closely related compounds was investigated. Arabinose, xylose, dextrose, galactose, mannose, levulose, sucrose, maltose, lactose, mannitol, glycerol, salicin, xylan, pyruvic, lactic, and malic acids are all decomposed more or less completely. Rhamnose, raffinose, melizitose, esculin, starch, inulin, cellulose, and succinic, tartaric, and citric acids are not attacked.—J. C. D.

Vitamines from yeast. Myers and Voegtlin. See XIXA.

PATENTS.

Malting process. R. de Fazi and F. Peroni. E.P. 143,121, 17.9.19. Conv., 22.5.19.

BARLEY, wheat, or other grain is exposed to ultra-violet rays during steeping and germination, whereby these processes are assisted.—L. E.

Alcohol and yeast from seaweed; Production of —. E. C. Bayer and S. Orlajensen. E.P. 119,030, 14.5.19.

SEAWEED is treated with hot water or a solution of salts such as chloride of lime, the extract being hydrolysed, e.g., by heating with 0.5% of sulphuric acid for 6 hrs. under a pressure of 3 atm., neutralised with calcium carbonate, and fermented with yeast. The residual seaweed is utilised for the production of algin.—L. E.

Acids; Utilisation of marine algæ for manufacture of formic, acetic, and butyric — [by fermentation] and for extraction of salts of iodine and potash. Darrasse Frères, and L. Dupont. E.P. 123,325, 13.2.19. Conv., 13.2.18.

THE material is fermented at, say, 35° C. with the bacteria on the algæ themselves, or with pure cultures obtained from earth manured with sea-wrack, the fermentation medium being kept slightly alkaline or neutral by addition of oxide, hydroxide, or carbonate of an alkali or alkaline-earth metal, or of the zinc or iron group. The organic acids formed are recovered, e.g., by distillation with sulphuric acid, the potassium sulphate in the residue is obtained by fractional crystallisation, and the iodine is precipitated from the mother liquor as cuprous iodide.—L. E.

Carbohydrate contained in plants, vegetable offal, and in natural or industrial waste products; Utilisation of —. Darrasse Frères, and L. Dupont. E.P. 123,326, 13.2.19. Conv., 13.2.18.

THE material is fermented with aceto-butyric bacteria found in earth fertilised with dung or dead leaves. Fermentation is effected preferably at 40°—50° C. for 2—3 days, and in presence of a neutralising agent such as oxides, hydroxides, carbonates, or other basic salts, in order to increase the yield of organic acids (formic, acetic, and butyric). The acids are separated by distilling the fermented product with a mineral acid. Since the cellulose substances are very little affected by the fermentation, the process serves for the preparation of pure cellulose fibre, provided the raw material consists of plants capable of yielding such fibre.—L. E.

Carbonating beverages. U.S.P. 1,338,352. See XI.

XIXA.—FOODS.

Bread; Colloid chemistry of —. I. *Colloid-chemical problems in the preparation of bread.* W. Ostwald. *Koll.-Zeits.*, 1919, 25, 26—45.

THE chief differences between flour, dough, and new and stale breads are of a physical rather than of a chemical nature. Each of these materials is essentially composed of colloidal particles, and by application of viscometric methods light may be thrown on such phenomena as the variation in the strength of flours, the process whereby bread becomes stale, variations in porosity of bread etc.

—H. W. B.

Bread; Colloid chemistry of —. II. *Viscometry of flour.* H. Lüers and W. Ostwald. *Koll.-Zeits.*, 1919, 25, 82—90, 116—136.

THE viscosity of mixtures of flour and water containing as much as 20% of flour can readily be determined by using large viscometers with large capillaries. The measurements must be made quickly owing to the tendency of the mixtures, even after boiling, to undergo sedimentation. The viscosity of rye mixtures is always considerably higher than that of mixtures of wheat flour and water of the same concentration. On keeping rye mixtures become more viscous, whilst wheat mixtures become thinner. Wheat suspensions are extremely sensitive to traces of acids, which greatly increase the viscosity; sodium chloride appears to reduce it. A flour of poor baking quality was found to give viscosity figures considerably below those given by normal flours.—H. W. B.

Bread; Colloid chemistry of —. III. *Colloid chemistry of rye and wheat gliadins, with special attention to gluten and baking problems.* H. Lüers. *Koll.-Zeits.*, 1919, 25, 177—196, 230—240.

THE viscosity of gliadin solutions is increased by traces of acids and alkalis and diminished by neutral salts. Changes in the gluten and in the baking qualities of flour appear to be dependent largely on changes occurring in the gliadin constituent of the gluten. The viscosity of gliadin solutions is greatly affected by changes of temperature, and the temperature at which the viscosity reaches a maximum is also the temperature at which the best dough and bread are produced. The addition of a trace of acid, which increases the viscosity of the gliadin solution, likewise improves the quality of the bread.—H. W. B.

Bread; Colloid chemistry of —. IV. *Flour of inferior baking quality.* H. Lüers and W. Ostwald. *Koll.-Zeits.*, 1920, 26, 66—67.

TWO further samples of flour with bad baking properties have been examined and found to give flour-water mixtures of abnormally low viscosity.

—H. W. B.

Milk; Carbon dioxide content of — a basis for distinguishing heated from unheated milk. L. L. van Slyke and R. F. Keeler. *J. Biol. Chem.*, 1920, 42, 41—45.

NORMAL milk shows a minimum value of 3.5—3 volume percentage of CO₂. Pasteurisation lowers this value below 3—2.5. This is of value in distinguishing the two classes of milk.—J. C. D.

Moisture in foodstuffs; Estimation of —. G. A. Stutterheim and H. Lazet. *Pharm. Weekblad*, 1920, 57, 457—462.

THE time necessary for the estimation of moisture in foodstuffs may be greatly shortened by assuming that with the same quantity of material and the same apparatus and conditions of experiment the ratio of the total moisture to the amount of

moisture lost in a given time is constant. The ratio factor is determined by numerous experiments. The method gave satisfactory results when applied to bread, cocoa, and sausages.—W. S. M.

Vitamine; Extraction of fat-soluble — from carrots, alfalfa [lucerne], and yellow maize by fat solvents. H. Steenbock and P. W. Boutwell. *J. Biol. Chem.*, 1920, 42, 131–152.

ALCOHOL is the best solvent to remove the fat-soluble accessory factor from these sources. Ether and other fat-solvents seldom give good results. The factor appears to resist saponification in the cold and to be associated with the fraction containing the lipochrome caroteno.—J. C. D.

Vitamines [from yeast]; Chemical isolation of —. C. N. Myers and C. Voegtlin. *J. Biol. Chem.*, 1920, 42, 199–205.

THE separation of an active crystalline fraction from dried yeast is described. The fraction readily loses its activity. (*Cf. J.C.S.*, July.)—J. C. D.

Aluminium vessels. Grossfeld. *See I.*

XIXB.—WATER PURIFICATION; SANITATION.

Calcium cyanamide. Siehner. *See XVI.*

Chloropicrin. Bertrand and Rosenblatt. *See XVIII.*

PATENTS.

Water; Process for softening and purifying —. A. Gawalowski and J. Overhoff. G.P. 319,436, 17.7.14

THE water is treated with a ferrate or perferrate of an alkali, alkaline-earth, or heavy metal, preferably by passing it through a filter or contact mass impregnated with the purifying agent so as to remove the insoluble reaction products at the same time as the impurities.—A. R. P.

Air; Continuous production of pure, germ-free —. A. Wolff. G.P. 316,516, 13.9.17.

AIR is washed with ozonised water (G.P. 307,433–4; *J.*, 1918, 747 A), to which may be added a substance capable of increasing the ozone-fixing power of the water. (*Cf. U.S.P.* 1,152,066; *J.*, 1915, 1010.)—W. J. W.

Fungicides containing lime-copper; Method of increasing the adhesion of —. H. Cailler and C. Arragon. G.P. 318,710, 29.8.18. *Conv.*, 14.6.18.

CASEIN, caustic alkalis, or alkaline earths, or calcium carbonate may be added to lime-copper mixtures to increase their adhesive properties.—W. J. W.

Boilers for distilling water. C. Turnbull. E.P. 142,669, 16.5.19.

Antifouling paint. E.P. 131,601. *See XIII.*

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Ipecacuanha preparations; Determination of ipecacuanhic acid in —. R. Heuerre. *J. Pharm. Chim.*, 1920, 21, 425–433.

AN aqueous extract of the sample is filtered and saturated with ammonium sulphate; the precipitate formed is collected, washed with ammonium

sulphate solution, and, while still wet, dissolved in 90% alcohol. The alcoholic solution is evaporated and the residue dissolved in water; the weight of total solids of this solution gives the amount of ipecacuanhic acid after allowance has been made for the small quantity of ammonium sulphate still present. The acid is insoluble in ethyl acetate, chloroform, amyl alcohol, and acetone, but soluble in water and in alcohol. It has a distinct cupric-reducing power, and is precipitated by many saturated salt solutions. Powdered ipecacuanha contains 3–4% of the acid.—W. P. S.

Croton resin. R. Boehm. *Arch. Exp. Path. Pharm.*, 1915, 79, 138–154.

THE optical activity of croton oil is due to a resin which is dissolved in it. On removing the resin from the oil by extraction with methyl alcohol, the oil becomes inactive. The optical rotation of croton oil may therefore serve as an indication of its resin content. The extraction, purification, properties, and pharmacological character of the resin are described. (*Cf. J.C.S.*, July.)—S. S. Z.

Sulphurised derivatives of proteins having therapeutic value; Production of —. A. Pellizza. Sealed note 1446, 22.1.14. *Bull. Soc. Ind. Mulhouse*, 1919, 85, 295–296. Report by C. Meininger, *ibid.*, 296–297.

SULPHURISED derivatives of proteins having therapeutic value may be produced by condensing egg albumin, casein, etc., in the cold with carbon bisulphide in the presence of sodium carbonate. The products are precipitated by dilute acids, and are purified by re-solution in alkalis and re-precipitation by acids. The sulphur content of egg albumin was by this method increased from 1.44% to 3.68–3.75%, the respective proportions of assimilable sulphur being 27.7% and 62%.—A. J. H.

Local anæsthetics; Relationship between chemical constitution and physiological action in —. 1. *Homologues of procaine (novocaine).* O. Kamm. *J. Amer. Chem. Soc.*, 1920, 42, 1030–1033.

THE structure of *p*-diethylaminopropyl *p*-aminobenzoate, m.p. 69° C. (hydrochloride, m.p. 164° C.), bears considerable similarity to that of cocaine. Correspondingly, in physiological action it is intermediate between cocaine and procaine, being slightly more toxic than the latter, but more effective for the production of surface anæsthesia. *p*-Diethylaminopropyl *m*-aminobenzoate is an oil (hydrochloride, m.p. 151° C.). (*Cf. J.C.S.*, July.)—J. K.

Dimethylaminoantipyrine (pyramidone); Analytical characters of —. J. A. Sánchez. *Anal. Soc. Quim. Argentina*, 1918, 6, 422–428, 513–521.

THE methods given include: the colorimetric determination of pyramidone by iodic acid; detection of pyramidone in presence of large quantities of antipyrine by silver nitrate; gravimetric separation of antipyrine and pyramidone with formaldehyde; detection of a small quantity of antipyrine in pyramidone by means of nitrous fumes; and the alkalimetric determination of pyramidone. (*Cf. J.C.S.*, July.)—W. R. S.

Glass for the manufacture of ampullæ; Selection of —. G. E. Ewe. *J. Franklin Inst.*, 1920, 189, 649–653.

GLASS tubing intended for the manufacture of ampullæ for sterilised pharmaceutical preparations must not yield alkali or produce spicules of glass in the process. A 1% solution of morphine sulphate or a 0.2% solution of strychnine sulphate in normal saline solution, must not become turbid or opalescent when sterilised in the ampulla previously washed with dilute hydrochloric acid and water. No glass spicules must be formed when a 0.6% sodium

chloride solution is sterilised in the vessel. Tests for alkalinity and results obtained with typical samples of glass tubing are given.—C. A. M.

Oxalic acid and oxalates; Action of heat on —. G. Calcegni. Gazz. Chim. Ital., 1920, 50, i., 245—251.

HYDRATED oxalic acid melts at 98° C. and yields carbon monoxide and dioxide in unequal volumes at 110°—120° C. The anhydrous compound, obtained by protracted storage of the hydrated acid in a vacuum over sulphuric acid, begins to turn pasty and to decompose at 135° C., complete fusion and vigorous decomposition and distillation occurring at 160°. Among the products of the thermal decomposition of ammonium oxalate are carbon monoxide and dioxide, ammonium carbonate, and apparently oxaminic acid. Sodium (or potassium) hydrogen oxalate yields more carbon monoxide than corresponds with the equations: $2\text{NaHC}_2\text{O}_4 = \text{Na}_2\text{C}_2\text{O}_4 + \text{CO}_2 + \text{CO} + \text{H}_2\text{O}$ and $\text{Na}_2\text{C}_2\text{O}_4 = \text{Na}_2\text{CO}_3 + \text{CO}$, while formic acid is also formed and the residue contains carbon. Normal potassium oxalate yields at first water and carbon monoxide and dioxide, possibly owing to contamination with the acid salt; later only carbon monoxide is evolved, leaving the carbonate and carbon. Calcium oxalate gives carbon monoxide as sole gaseous product, while the residue contains calcium carbonate and carbon and, as it reduces silver nitrate solution, probably the formate as well. Barium and strontium oxalates behave similarly to the calcium salt, whilst magnesium oxalate decomposes directly into carbon monoxide and dioxide and magnesium.—T. H. P.

Acids; Identification of [organic] —. V. *p*-Halogeen phenacyl esters. W. L. Judefind and E. E. Reid. J. Amer. Chem. Soc., 1920, 42, 1043—1055.

A NUMBER of the phenacyl esters previously described (J., 1919, 199A) are oils, or solids of low melting-point. The *p*-bromoacetophenone previously used has therefore been replaced by its *p*-chloro-, bromo-, and iodo-derivatives, with the result that the esters obtained are found to have a range of melting-points very convenient for their identification. The esters of maleic, racemic, tartaric, and asparaginic acids decomposed without melting, whilst esters could not be obtained from gallic, linolic, oleic, oxalic, monochloroacetic, trichloroacetic, and formic acids. A liquid ester was obtained from α -hydroxybutyric acid. (Cf. J.C.S., July.)—J. K.

Formaldehyde; Preparation of —. M. D. Thomas. J. Amer. Chem. Soc., 1920, 42, 867—882.

FORMALDEHYDE is prepared with an absolute yield of 95% and a process yield of 55·6% by passing air at 125—150 l. per hr. through methyl alcohol and then over a coil of silver gauze heated to 400° C. The coil is only heated at the commencement of the process and afterwards is kept hot by the heat of the reaction. The yields with gold and copper spirals are rather less (50·5 and 40% respectively). With silver the best yield is obtained if the gas contains 0·4—0·5 g. of oxygen per 1 g. of alcohol. The presence of 1·7% of acetone or 10% of water does not influence the yield appreciably. (Cf. J.C.S., July.)—J. F. S.

Water; Detection of — in alcohol and other organic solvents. F. Henle. Ber., 1920, 53, 719—722.

A XYLENE solution of partially decomposed aluminium ethoxide is prepared by allowing aluminium turnings (27 g.), absolute alcohol (276 g.) and mercuric chloride (0·2 g.) to react until the evolution of hydrogen subsides and heating the product on the water bath until it appears dry. The alcohol of crystallisation is then distilled from an oil bath at 210°—220° C., and the crude aluminium ethoxide is subsequently cautiously heated to about

310° C. (thermometer immersed in the molten mass); after about 1 hr. the temperature falls to about 330° C. and heating is then discontinued. The product, whilst still hot, is dissolved in $\frac{1}{2}$ l. of boiling xylene and the solution is filtered through a dry paper; the clear, pale yellowish-brown filtrate can be preserved indefinitely if air and moisture are excluded. If a few drops of the reagent be added to a few c.c. of the liquid under examination, then, according to the quantity of water present, a voluminous, gelatinous precipitate of aluminium hydroxide is formed immediately or in the course of a few seconds. The percentage of water which can thus be detected in various solvents is as follows: ethyl alcohol, 0·05; methyl alcohol, 0·1; ether, 0·005; ethyl acetate, 0·1; acetaldehyde, 0·1; acetone, 1. The two substances last named also yield white turbidities due to the precipitation of aluminium ethoxide from the reagent, but these can be readily distinguished from aluminium hydroxide, since they immediately disappear on addition of a larger excess of reagent or of xylene. (Cf. J.C.S., July.)—H. W.

Removing sulphur from organic compounds. Herzog. See IV.

Bromine [in organic matter]. Wünsche. See XXIII.

PATENTS.

Cymene; Manufacture of para —. British and Foreign Chemical Producers, Ltd. From Rheinischo Kampferfabrik Ges. E.P. 142,738, 6.10.19.

THE terpenes of b.p. 175° C. obtained by the elimination of hydrogen chloride from the liquid additive compounds of pinene and hydrogen chloride, or the fractions of the same b.p. from Swedish and Polish turpentine oils, are chlorinated and then distilled with steam. *p*-Cymene, in yield approximating to 60% of that theoretically obtainable, is thus produced and is purified by treatment with suitable oxidising agents, such as potassium permanganate, or polymerising agents, such as zinc chloride.—D. F. T.

Organic substances; Purification of — by sublimation. The Selden Co., and J. McC. Selden. E.P. 142,902, 3.2.19.

THE constituents of a mixture of sublimable solid organic substances are separated by vaporising at least a part of the mixture into a current of substantially inert gas and fractionally crystallising by cooling the vapour mixture progressively in a chamber comprising a series of compartments of graded temperatures. Anthracene may thus be separated from crude anthracene press cake and phthalic anhydride from naphthalene, while crude anthraquinone, naphthalene, benzoic acid, and salicylic acid may be separated from their common impurities. (Cf. U.S.P. 1,321,716—7 of 1919; J., 1920, 100A.)—D. F. T.

Acids and acid anhydrides; Manufacture of organic —. M. Moest and E. Schirm, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,337,253, 20.4.20. Appl., 27.5.16. Renewed 26.6.19.

ORGANIC acids and acid anhydrides are prepared by the action of oxides of nitrogen, intermediate in composition between nitric oxide and nitrogen pentoxide, on salts of organic acids.—G. F. M.

Ethyl sulphates; Process of making —. H. R. Curme, Assr. to Union Carbide Co. U.S.P. 1,339,947, 11.5.20. Appl., 7.7.19.

EXCESS of ethylene is treated with sulphuric acid with formation of ethyl hydrogen sulphate and diethyl sulphate; the latter is entrained with the excess of ethylene and separated subsequently.

—D. F. T.

Mercury sludge from electrolytic processes; Conversion of — into metallic mercury. Konsortium für Elektrochemische Ind. G.P. 319,476, 14.5.18.

THE sludge is stirred with acid liquids, to which small quantities of metals, such as zinc or iron, are added to liberate hydrogen. In certain cases, such as the production of acetaldehyde from acetylene, the formation of sludge may be avoided by adding these metals during the process.—W. J. W.

Photochemical apparatus. U.S.P. 1,339,675. See I. *Marine algæ.* E.P. 123,325. See XVIII.

Carbohydrate in plants etc. E.P. 123,326. See XVII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Photographic sensitising dyes of the isocyanin type; Process of making —. L. E. Wise and E. Q. Adams. U.S.P. 1,338,346, 27.4.20. Appl., 10.2.19.

PHOTOGRAPHIC sensitising dyes are prepared by the interaction of sodium methoxide in absolute methyl alcoholic solution with mixtures of the quaternary halide addition products of an α -methylated quinoline derivative and of a γ -unsubstituted quinoline derivative.—G. F. M.

Photo-sensitising-dyes effective for infra-red radiation; Process of making —. E. Q. Adams and L. E. Wise. U.S.P. 1,338,349, 27.4.20. Appl., 4.4.19.

INFRA-RED photographic sensitising dyes are prepared by the interaction of air and sodium methoxide in absolute methyl alcoholic solution with the quaternary halide addition products of α -dimethylated quinoline derivatives.—G. F. M.

XXII.—EXPLOSIVES; MATCHES.

Military explosives; Theoretical maximum pressure developed by — in their own volume. J. E. Crawshaw. J. Franklin Inst., 1920, 189, 607—625.

A METHOD is described for calculating from experimental results the maximum pressure which an explosive would exert if exploded or detonated within a space which it fills completely, and tables are given showing the values obtained for 13 different explosives at varying densities.—C. A. M.

Picric acid; Preparation of —. Influence of the degree of sulphonation on the yields of trinitrophenol. M. M. Doll. Bull. Soc. Chim., 1920, 27, 370—374.

OTHER things being equal, the yield of trinitrophenol increases with the degree of sulphonation of the phenol.—W. G.

PATENTS.

Explosives; Manufacture of —. G. A. Hedberg. E.P. 142,763, 30.12.19. Addition to 140,967 (see U.S.P. 1,335,785; J., 1920, 429 A).

PINE-BARK meal to be used as an ingredient for explosive mixtures is ground to an extreme fineness, so that it gives a weight when loosely filled of 24 lb. per cub. ft., as compared with 15 lb. per cub. ft. obtained hitherto.—W. J. W.

Explosive. J. A. Hardel. U.S.P. 1,337,451, 20.4.20. Appl., 4.2.19.

AN explosive mixture contains a liquid nitro-hydrocarbon derivative saturated with a solid nitro-hydrocarbon derivative.—W. J. W.

XXIII.—ANALYSIS.

Turbidimeter; Photometric —. W. G. Bowers and J. Moyer. J. Biol. Chem., 1920, 42, 191—198.

AN attempt to devise a more accurate instrument for comparison of turbidities. The photometric oil spot is applied to the turbidimeter to balance intensities of illumination.—J. C. D.

Measuring and circulating gases soluble in water; Apparatus for —. B. Neumann and H. Schneider. Z. angew. Chem., 1920, 33, 128.

AN apparatus for measuring and circulating small quantities of gases soluble in water comprises two pipette-shaped glass vessels, terminating at their upper ends in T-pieces with two taps, and provided with a single tap below, the two vessels being connected at both ends by tubes, and communicating with a levelling tube and a gas collector, the gas in the latter being controlled by a pressure vessel. A lateral branch from the top connecting tube leads to a gas-reacting vessel or any desired apparatus. The glass vessels are half filled with water, previously saturated with the gas, which acts as a seal for the gas during its passage, and by suitable manipulation of the various taps, the gas may be introduced into either vessel and measured. (Cf. J.C.S., July.)—W. J. W.

Qualitative analysis of cations of the third and fourth groups. P. de Pauw. Chem. Weekblad, 1920, 17, 191—192.

AFTER treatment with hydrogen sulphide the acid filtrate is treated with sodium sulphate solution, which precipitates barium, strontium, and, in part, calcium. The filtrate contains iron, cobalt, nickel, manganese, chromium, aluminium, zinc, calcium, magnesium. Solid sodium carbonate and sodium hydroxide are added and, after boiling, sodium sulphide. The precipitate contains all the metals except aluminium. Dilute hydrochloric acid dissolves the precipitate except a residue of nickel and cobalt sulphides. To this solution solid carbonate is added and then sodium hypochlorite. Zinc and chromium remain in solution as zincate and chromate respectively and may be separated by means of barium chloride. The residue consists of ferric hydroxide, hydrated manganese dioxide, calcium and magnesium carbonates. This is treated with 5% acetic acid containing a little phosphate, which dissolves calcium and magnesium as acetates. The residue is dissolved in sodium peroxide and nitric acid and examined for iron and manganese in the usual way.—W. S. M.

Gravimetric analysis; Theory of — with special reference to sources of error. L. Moser. Z. anal. Chem., 1920, 59, 1—10.

THE author discusses the various sources of error in gravimetric analysis, classified as avoidable and unavoidable.—W. P. S.

Colorimetric estimations with solutions containing two coloured substances. K. G. Falk and H. M. Noyes. J. Biol. Chem., 1920, 42, 109—130.

UNLESS the standard and unknown solutions are very nearly alike in composition and concentration such methods are open to grave errors.—J. C. D.

Chromium and manganese; Separation of —. M. Herschkowitsch. Z. anal. Chem., 1920, 59, 11—12.

CHROMIUM and manganese, in solution, are oxidised to chromate and permanganate respectively, and the solution is heated for some hours with the addition of ammonium sulphate and an excess of ammonia. The manganese is precipitated completely and may be collected and weighed as Mn_2O_3 , whilst the chromate remains in solution.—W. P. S.

Ferric hydroxide; Carrying down of calcium and magnesium hydroxides by precipitates of —. Toporescu. *Comptes rend.*, 1920, 170, 1251—1253.

Ferric hydroxide when precipitated tends to carry down with it both calcium and magnesium hydroxides if salts of these metals are present in the solution, and this is not entirely prevented by the presence of 2% of ammonium chloride. Any calcium hydroxide thus carried down may be removed either by washing the precipitate with a 5% boiling solution of ammonium nitrate or by dissolving the precipitate in acid and re-precipitating. Neither of these processes is adequate for the complete removal of any magnesium hydroxide carried down.

—W. G.

Nitrosoindole test. [Detection of nitrates.] J. Groenewege. *Med. Geneesk. Lab. Weltevreden*, 1919, 177—193.

WHEN certain organisms (*e.g.*, cholera vibrios) are grown on peptone medium the latter gives the nitrosoindole reaction (red coloration) when treated with a drop of mineral acid, the reaction being obtained without the addition of nitrite. This is due to the presence of nitrite formed by reduction of traces of nitrate present in the peptone. The reaction is not given if the peptone medium is inoculated previously or simultaneously with a denitrifying organism which reduces the nitrate to ammonia or nitrogen. Traces of nitrate may be detected by adding the substance to be tested to a culture of cholera vibrios *etc.*, in peptone medium freed from nitrate as described, and then applying the nitrosoindole test.—W. P. S.

Gas analysis; Exact methods of —. E. Ott. *J. Gasbeleucht.*, 1920, 63, 198—205, 213—220, 246—252, 267—271.

A GAS-ANALYSIS apparatus is described of the constant pressure type, with control tube, the gases being stored over mercury. Carbon monoxide and hydrogen are estimated separately or together by burning in contact with platinum wire at 300° C., the wire or wires being enclosed in a silica capillary tube, which is preferable to a platinum tube, being non-porous and less expensive. Methane does not combine with oxygen at 300° C., but commences to do so at 400° C., burning completely at bright red heat. Measured quantities of the pure gases were mixed together and check analyses carried out by completely burning all the gas and measuring the oxygen used up and the carbon dioxide produced; by absorbing the carbon monoxide first with ammoniacal cuprous chloride followed by fractional combustion of the methane and hydrogen; and by fractional combustion, first of the hydrogen and carbon monoxide together, followed by that of the methane. The apparatus and method of manipulation are described in detail, together with the results of the check analyses. The platinum wire must be re-vivified or replaced from time to time.—W. P.

Bromine [in organic matter]; Estimation of —. F. Wütsche. *Arch. Exp. Path. Pharm.*, 1919, 84, 328—339.

THE substance is heated with sodium peroxide in a nickel basin first on the water bath, then over a free flame, and eventually incinerated. The ash is washed out with distilled water, the solution filtered, and the filtrate neutralised with concentrated sulphuric acid and treated with potassium permanganate and sulphuric acid. The free bromine is blown over by means of a current of air into a vessel containing a known volume of fuchsine and sulphurous acid, and estimated colorimetrically by comparing the violet coloration which is produced with a set of standards. 2 mg. of neuronal was estimated in 30 c.c. of blood with an error of 12%. Neuronal, adaline, and bromural were estimated in frog's tissue by this method with an error of about 7%.—S. S. Z.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

- Adams. Purifying liquids. 16,125. June 15.
 Allgem. Ges. f. Chem. Ind. Carrying out operations at high temperature in an air-free space. 17,056. June 23. (Ger., 13.3.19.)
 Ayres. Process of refining liquids. 16,412. June 17. (U.S., 3.10.17.)
 Brownlee and Ganahl. Heat treatment of liquids. 16,776. June 21.
 Elektro-Osmose A.-G. Leaching vegetable, animal, or mineral substances. 16,113. June 14. (Ger., 9.1.15.)
 Feldenheimer and Plowman. Catalysts and catalytic reactions. 16,917. June 22.
 Fuller-Lehigh Co. Pulveriser mills. 16,760. June 21. (U.S., 1.6.18.)
 Heisch. Apparatus for precipitating solids by action of gas on liquids. 16,529. June 18.
 Hewitt. Removal of liquids from pastes, wet precipitates, and crystalline magmas. 16,803. June 22.
 Hunt. Apparatus for maintaining finely-divided solids in suspension in liquids *etc.* 16,612. June 19.
 Lilienfeld and others. 16,726. See XI.
 Krause. Evaporation of solutions and effecting chemical reactions. 16,320. June 16. (Ger., 29.1.17.)
 Metallbank u. Metallurgische Ges. Production of solid bodies in fine powder from liquids, pulpy masses, *etc.* 16,172. June 15. (Ger., 16.4.18.)
 Skinninggrove Iron Co., and Smith. 16,701. See XI.

COMPLETE SPECIFICATIONS ACCEPTED.

- 20,169 (1918). Frey and Henz. Suppressing froth or scum when boiling liquids. (121,293.) June 23.
 5730 (1919). Gay. Absorption, reaction, distillation, rectification, and like columns. (144,374.) June 23.
 6330 (1919). Chemical Equipment Co. Corrosive fluid valves. (124,445.) June 30.
 7052 (1919). Summers and Whittard. Rotary furnaces, retorts, *etc.* (141,815.) June 30.
 9819 (1919). Smith. Furnace retorts. (126,614.) June 30.
 30,112 (1919). Watt. Treating filtration membrane. (144,961.) June 30.
 3664 (1920). Elmore. Centrifugal dryers. (144,979.) June 30.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

- Auburtin and others. Coke-gas generator. 17,050. June 23. (Fr., 23.6.19.)
 Bateman. Heating vertical retorts for gasifying coal etc. 16,144. June 15.
 Chadbourn and Remington. Production of hydrocarbons from oil-bearing minerals. 16,088. June 14.
 Coe. Treatment of peat. 16,181. June 15.
 Farbenfabr. vorm. F. Bayer u. Co. 17,178 and 17,198. *See VII.*
 Farb. vorm. Meister, Lucius, u. Brüning. Manufacture of methane. 16,757 and 16,905. June 21 and 22. (Ger., 28.6. and 1.7.19.)
 Fischer. Distillation of coal. 17,174. June 24. (Ger., 13.11.16.)
 Fyelman and Sprott. Purification of acetylene. 16,528. June 18.
 Robin. Treatment of fabrics for gas mantles. 16,898. June 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 6445 (1919). Hood. Recovery of cyanogen from coal gas. (144,398.) June 23.
 9819 (1919). Smith. *See I.*
 13,606 (1919). Campbell. Process of making gas. (144,868.) June 30.
 21,478 (1919). Wells. Gas-producers. (144,520.) June 23.
 10,496 (1920). Griffin. Enrichment of producer-gas. (144,989.) June 30.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

- British Dyestuffs Corp., and others. 16,179 and 17,037. *See XX.*
 Brock and others. 17,238. *See XIII.*
 Irinyi. Distillation of tar etc. 17,347. June 25. (Ger., 25.11.18.)

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

- Act.-Ges. f. Anilinfabr. Manufacture of azo dyestuffs. 16,198—16,202. June 15. (Ger., 4.6, 29.6, 28.7, 31.7.15, and 18.1.18.)
 Act.-Ges. f. Anilinfabr. Manufacture of sulphurised dyestuffs. 16,906—7. June 22. (Ger., 21.1.14.)
 British Dyestuffs Corp., Perkin, and Clemo. Manufacture of benzaldehyde derivatives and triphenylmethane colouring matters. 17,038. June 23.
 Johnson (Badische Anilin u. Soda-Fabr.). Manufacture of intermediate products and colouring matters, and their application in dyeing and printing. 16,299. June 16.
 Soc. Chim. des Usines du Rhône. Dyestuffs of the indigo series. 16,523. June 18. (Fr., 14.10.19.)

COMPLETE SPECIFICATION ACCEPTED.

- 20,799 (1918). Hart. Production of water-soluble dyes. (144,336.) June 23.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Act.-Ges. f. Anilinfabr. Manufacture of cellulose esters. 16,903—9. June 22. (Ger., 11.7.14 and 30.5.18.)
 Badische Anilin u. Soda-Fabr. Production of solutions of cellulose acetates. 16,861. June 22. (Ger., 9.2.14.)
 Bennert. Treating and scouring wool etc. 16,546. June 18. (Ger., 8.2.15.)

British Cellulose and Chemical Manufacturing Co. Cellulose-ester compositions. 17,435. June 26. (U.S., 30.6.19.)

- Burgess, Ledward and Co., and Harrison. Treatment of cellulose fibres or substances. 16,649. June 21.
 Charbonneau. Treatment of flax etc. 17,091. June 23. (Fr., 20.2.18.)
 Folien u. Flitterfabr. A.-G. Obviating high inflammability of celluloid. 16,458. June 17. (Ger., 13.9.17.)
 Glanzfäden A.-G. Preparing durable cupric-ammonia cellulose solutions for spinning artificial threads etc. 16,075. June 14. (Ger., 12.10.17.)
 Hartridge and Newcombe. Manufacture of waterproof paper. 16,916. June 22.
 Kaye. Use of new materials in paper making. 17,252. June 25.
 Robin. 16,898. *See II.*
 Simons (Sager). De-inking paper for re-pulping. 16,437. June 17.

COMPLETE SPECIFICATIONS ACCEPTED.

- 8086 (1919). Dorr Co. *See VII.*
 31,192 (1919). Gillet et Fils. Treatment of vegetable fibres. (144,563.) June 23.
 1597 (1920). Bonwitt. Manufacture of dissolved or gelatinous cellulose esters. (138,078.) June 23.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Bennert. Preparation of dye-baths. 16,892. June 22. (Ger., 24.12.15.)
 Hitchen. Printing warps or yarns. 16,831. June 22.
 Johnson (B.A.S.F.). 16,299. *See IV.*
 Mitchell. Waterproofing fabric. 16,783. June 21.
 Petty. Dyeing textiles. 16,607. June 19.
 Wioland. Dyeing and bleaching apparatus. 16,409. June 17. (Fr., 7.7.19.)

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Audianne. Apparatus for manufacture of sulphuric anhydride. 16,731. June 21.
 Badische Anilin u. Soda-Fabr. Manufacture of nitrogen-hydrogen mixtures for synthetic production of ammonia. 16,209. June 15. (Ger., 2.7.15.)
 Badische Anilin u. Soda-Fabr. Production of oxides of nitrogen from ammonia by catalytic oxidation. 16,210. June 15. (Ger., 1.4.16.)
 Badische Anilin u. Soda-Fabr. 16,086. *See XVI.*
 Bergve. Manufacture of alkaline reducing agents. 16,936. June 22.
 Codrington. 16,146. *See X.*
 Crossley. Mica, mica compounds, etc. 17,066. June 23.
 Farbenfabr. vorm. F. Bayer u. Co. Purifying gases containing hydrogen sulphide and obtaining sulphur. 17,178 and 17,198. June 24. (Ger., 24.5.17 and 3.7.18.)
 Levinson and Martin. Utilising waste lime sludge. 16,534. June 18.
 Maucelaire and Nouvelle. Apparatus for producing hydrogen. 16,578. June 18.
 Metallbank u. Metallurg. Ges. Treating sal ammoniac skimmings. 16,392. June 17. (Ger., 28.2.18.)
 Naef. 16,586. *See X.*
 Röhm. Production of solid non-hygroscopic iron salts. 17,437 and 17,453. June 26. (Ger., 27.12.18 and 11.4.19.)
 Soc. Electro Metallurgique Française. Preparation of aluminate of lime for manufacture of pure alumina. 17,062. June 23. (Fr., 7.3.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

3621 (1919). British Oxygen Co., Bray, and Balfour. Manufacture of hydrogen. (144,751.) June 30.

6445 (1919). Hood. *See* II.

7131 (1919). Jackson (Sperry). Producing lead salts. (144,819.) June 30.

8086 (1919). Dorr Co. Manufacture of caustic soda, particularly from pulp digestion residues. (131,272.) June 30.

11,654 (1919). Bergve. Decomposition of alkali aluminosilicates. (127,566.) June 23.

13,660 (1919). Clark. Removal of arsenic from sulphuric acid. (144,869.) June 30.

24,040 (1919). Clayton. Apparatus for making oxygen compounds of sulphur. (141,661.) June 30.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Adair. Drying china clay. 16,017. June 14.

Corning Glass Works. Glass compositions. 16,452. June 17. (U.S., 26.2.17.)

Giddens, Hoxby, Rudd, and R. G. H. Furnace Co. Glass furnaces. 16,303. June 16.

Gimingham. Glass manufacture. 16,436. June 17.

Porzellanfabr. Kahla. Sweigniederlassung Freiberg. Cement for joining porcelain bodies after burning. 16,047. June 14. (Ger., 6.10.17.)

Schiff. Manufacture of dental cements. 16,196 and 16,297. June 15 and 16.

Truel. Glass-melting tanks or furnaces. 16,191. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

21,443 (1918). Shaw, Shaw, and Shaw. Furnace for melting glass etc. (144,744.) June 30.

5441 (1919). Denis. Manufacture of porous refractory material. (144,359.) June 23.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Larson. Manufacture of porous mortar products. 17,312. June 25. (Norway, 3.7.19.)

Schiff. 16,196 and 16,297. *See* VIII.

Schol. 16,067. *See* X.

COMPLETE SPECIFICATION ACCEPTED.

2775 (1919). Thompson (Arentox Co.). Protecting and fireproofing wood etc. (144,342.) June 23.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Aoyagi. Electrometallurgical manufacture of ductile bodies of high-fusing metals etc. 16,389. June 17.

Bayer. Transforming mineral stuffs. 16,640. June 19.

Bingham. Manufacture of rustless steel. 16,013. June 14.

Bowen. Furnaces for melting metals etc. 16,242. June 16.

Caink, and Radiant Products, Ltd. Annealing etc. metals. 16,881. June 22.

Codrington. Manufacture of lead and lead compounds. 16,146. June 15.

Gillespie. Manufacture of finely-divided metals and alloys. 16,742. June 21.

Jones. Coating metal. 16,325. June 16.

Krupp. Production of low-carbon ferrochromium. 17,388, 17,392—3. June 26. (Ger., 27.7.16, 3.10.16, 11.1.18.)

McKenna. Treating ferrotitanium to eliminate impurities. 16,559. June 18. (U.S., 11.8.16.)

Metallind. Schiele u. Bruchsalser. Welding aluminium to iron. 16,107. June 14. (Ger., 27.6.18.)

Minerals Separation, Ltd. (Wilkinson). Ore concentration. 17,092. June 23.

Naef. Manufacture of nickel and nickel salts. 16,586. June 19.

Naef. Manufacture of copper. 16,587. June 19.

Schol. Obtaining porous slag in dry state. 16,067. June 11. (Ger., 15.9.13.)

Thal. Apparatus for producing steel. 16,020—1. June 11. (Fr., 25.11.15, 20.2.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

4668 (1917). Stahlwerke Lindenberg A.-G. Steel alloy. (144,326.) June 23.

16,270 (1919). Gush. Furnace for hardening high-speed steel etc. (144,486.) June 23.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Allgem. Ges. f. Chem. Ind. Heating device in electric resistance furnaces. 17,055. June 23. (Ger., 13.3.19.)

Aoyagi. 16,389. *See* X.

Forshee. Electrodes. 16,576. June 18. (U.S., 18.3.20.)

Lilienfeld, and Metallbank u. Metallurg. Ges. Electrical gas purification. 16,726. June 21. (Ger., 8.8.18.)

Pechkrantz. Electrolysers. 17,348. June 25. (Switz., 27.6.19.)

Skinningrove Iron Co., and Smith. Electrostatic plant for depositing dust etc. from gases. 16,701. June 21.

COMPLETE SPECIFICATIONS ACCEPTED.

6654 (1919). Morgan Crucible Co., and Speirs. Electrically-heated furnaces. (144,802.) June 30.

10,357 (1919). Campbell and others. Control of power absorbed in an electric furnace. (144,438.) June 23.

17,902 (1919). British Thomson-Houston Co., and Hastings. Electric arc furnaces. (144,503.) June 23.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Ayres. Recovering neutral oils from their "foots" or soap stock. 16,411. June 17. (U.S., 21.5.17.)

De Bruyn, Ltd., and Revis. Treatment of edible oils etc. 16,711. June 21.

Dunham. Emulsifiable oil material in dry form. 16,893. June 22.

Dunham. Casein-oil product. 16,894. June 22.

Durden. Apparatus for extracting oil from nuts, seeds, etc. 17,206. June 24.

Elektro-Osmose A.-G. Decolorising liquids containing glycerin. 16,114. June 14. (Ger., 1.4.19.)

Fujimura and others. Apparatus for hardening fatty oils. 16,090. June 14. (Japan, 12.1.20.)

Johnston. 17,231. *See* XIX.

Persapol Ges. Manufacture of soaps. 16,786. June 21. (Ger., 10.10.16.)

Reinfurth. Manufacture of detergents. 17,475—6. June 26. (Ger., 31.7.16, 5.3.18.)

Rhodes. Soap. 16,289. June 16.

Warburton. Refining oils. 16,567. June 18.

COMPLETE SPECIFICATIONS ACCEPTED.

15,419 and 15,422 (1919). Blair, Campbell, and McLean, Blair, and Ferguson. Apparatus for hydrogenating oils and fats. (144,478—9.) June 23.

1841 and 1975 (1920). Verein. Chem. Werke. *See* XVIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Brock, Redman, and Weith. Manufacture of phenolic condensation products. 17,238. June 24. (U.S., 6.6.18.)

Ivinson and Roberts. Paint etc. impervious to oils, spirits, etc. 16,708. June 21.

Walpole. Production of resin from solvent naphtha. 16,280. June 16. (Ger., 1.2.16.)

COMPLETE SPECIFICATION ACCEPTED.

13,048 (1919). Grant. Drying-oil, giving a flat surface paint. (144,862.) June 30.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Pratt. Vulcanised articles and process for producing same. 17,366. June 25.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Bevis. Treatment of leather. 16,305. June 16.
Bloxam (Gerb- u. Farbstoffwerke Renner u. Co.). Manufacture of tanning agents. 17,203 and 17,340. June 24 and 25.

Fairweather (Luftfahrzeugbau Schütte-Lanz). Producing glue from blood. 17,308. June 25.

Gerb- u. Farbstoffwerke Renner u. Co. Manufacture of tanning agents. 17,293—5, 17,341—3, 17,461. June 25 and 26. (Ger., 10, 16, and 28.2.14, 7.7.15, 12 and 21.11.18, 31.7.19.)

McQuitty. Manufacture of sheets of edible gelatin. 16,743. June 21. (U.S., 20.6.19.)

Strain. Manufacture of sheet gelatin. 16,686. June 21.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Acid-proof and oil-proof containers. T. W. Jones. E.P. 143,651, 5.3.19.

THE interior surface of the container is coated with a layer of fireproof cement of the kind known as "hard finish plaster" so as to give a surface having a fine and even porosity. When dry and set, the surface is washed with petrol and then varnished with an alcoholic solution of shellac.

—W. H. C.

Drying machinery. A. A. Short and W. G. Watkins. E.P. 143,707, 16.5.19.

A HEATED gas passes through the central cylinder of a rotary dryer and then returns through a conduit which is provided with a valve, so that the whole of the gas may be made to return in contact with the material or part in contact with the material and part through an exterior jacket.

—W. H. C.

Drying machinery. A. A. Short and W. G. Watkins. E.P. 143,708, 16.5.19.

THE inner of a pair of co-axial cylinders is supported by tangential H-shaped stays, which are attached at one end to the outer cylinder and at the other to a collar which surrounds the inner cylinder and allows slight peripheral movement. The heating agent passes through the inner cylinder and/or around the outer cylinder, and the material to be dried passes through the space between the cylinders.—W. H. C.

Drying-kiln. C. A. Cutler. U.S.P. 1,341,884, 1.6.20. Appl., 26.8.18.

IN a drying-kiln constructed with a false ceiling and a number of supports above the floor, air openings are provided in the ceiling and false ceiling, air blasts in the space between the floor and the supports above it, and an air exhaust duct opening near the bottom of the kiln.—B. M. V.

Muffle furnace. W. O. Amsler. U.S.P. 1,341,031, 25.5.20. Appl., 3.4.16.

IN a single open-ended muffle furnace the gas is admitted above the muffle and, mixed with preheated air, it burns in a series of transverse combustion chambers adjacent to the top of the muffle; the products of combustion pass downwards around the muffle to a recuperator below in which the air supply is preheated.—J. H. L.

Furnace and [iron alloy] lining therefor. J. P. Copland, Assr. to The Elyria Iron and Steel Co. U.S.P. 1,341,299, 25.5.20. Appl., 10.8.18.

THE furnace lining is of cast metal consisting of Fe 70—75, Cr 15—25%, the remainder being a metal of the iron group.—B. M. V.

[Heat] recuperator. C. L. Trinks, Assr. to Tate-Jones and Co., Inc. U.S.P. 1,342,073, 1.6.20. Appl., 28.8.19.

THE conduit for conveying the air to be heated is made of metal, the low temperature end being of low, and the high-temperature end of high, heat-resisting quality.—B. M. V.

Heating furnace. C. L. W. Trinks, Assr. to Tate-Jones and Co., Inc. U.S.P. 1,342,074, 1.6.20. Appl., 28.8.19.

A FURNACE is constructed with thin refractory walls, roof, etc., enclosed in a metallic casing, having on its outer surface spacing ribs adapted to direct the flow of air along the casing. A second set of walls and roof of heat-insulating material

rest against the ribs and are enclosed in an outer metallic casing.—B. M. V.

Filling material for gas-absorption towers. Kunstler und Co. G.P. 319,558, 2.10.17.

THE filling material consists of strips of sheet metal, wider at one end than at the other, wound into spirals so that the narrower part is outside; the distance between two consecutive coils is smaller than the width of the outermost layer of metal.—A. R. P.

Ovens for baking, drying, and other purposes. C. Bucci. E.P. 143,809, 2.1.20.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Nitrogen in coal, coke and tar. Determination of —. A. Parker. Gas J., 1920, 150, 624—625.

THE unreliability of the Kjeldahl method as applied to fuels is confirmed (*cf.* J., 1919, 399A). A modified Dumas method is described which gave more satisfactory results. Pure carbon dioxide, washed by passage through a solution of sodium carbonate, was passed through a strongly heated silica tube lined with asbestos paper and containing a platinum boat charged with 15 g. of potassium chlorate for subsequent generation of oxygen; 3 g. of ignited copper oxide powder; 10 g. of ignited copper oxide powder mixed with 1 g. of sample; 30 g. of ignited copper oxide; and 15 cm. of reduced copper gauze spiral. In the case of tars the sample was placed between layers of copper oxide in a boat. When the combustion with copper oxide was ended, the chlorate, previously cool, was heated to develop a small quantity of oxygen, which completed the combustion of the sample. The gases were collected in a nitrometer and the nitrogen measured after absorption of carbon dioxide, oxygen, and carbon monoxide in the usual way.

—H. J. H.

Carbonisation of coal in vertical retorts with steaming. Fourth Report of Research Sub-Committee of Gas Investigation Committee of Inst. Gas Eng., June, 1920. Gas J., 1920, 150, 604—631.

TESTS were made to study the effect of steaming the charge during carbonisation in a Glover-West vertical retort plant at Uddington Gas Works near Glasgow, using a Lanarkshire coal, a typical analysis of which was:—moisture 9.8%, volatile matter 32.7%, fixed carbon 50.5%, ash 7.0%. Five tests are reported with varying proportions of steam and the detailed results are tabulated. Thermal balance sheets on a dry coal basis are also given. The results showed that there was a rise in the thermal efficiency of gas production (ratio of the heating power of the gas to this quantity plus the heat expended in its production) as the

proportion of steam was increased until a maximum was reached at 32.7% added steam. More drastic steaming caused a decrease in efficiency. The composition of the gases produced showed that a considerable quantity of methane as well as water-gas was produced by steaming. The results are analysed in numerous tables showing how the heat was utilised in the process, also giving the weight balances of the carbon, nitrogen, and sulphur and their distribution in the products. Analyses of tar, liquor, and benzol obtained by oil washing are also given. Two tests are reported in which much more extensive steaming was practised with a view to effecting complete gasification. This was practically achieved, the residue drawn containing 94.9% of ash, but the fuel consumption for heating the retort and for the production of the steam exceeded the heating power of the coal treated. Practical details of the tests are given in an appendix and also of the analytical methods employed (*cf.* Parker, *ante*).—H. J. H.

Gas production; Oxygen in —. H. J. Hodsman and J. W. Cobb. *Inst. Gas Eng.*, June, 1920. *Gas J.*, 1920, 150, 640–647.

THE carbonisation of coal and the gasification of the coke residue by a suitable air-steam blast are almost thermally neutral processes. Theoretically then the production of gaseous fuel should be attainable at very little cost of fuel. The considerable expenditure of heat in modern carbonisation practice is occasioned by the difficulty inherent in external heating at a high temperature. When internal heating is applied as in producer practice, dilution with atmospheric nitrogen involves certain heat losses and also difficulties in distribution and utilisation. The elimination of inert constituents as in the water-gas process is only achieved at the cost of further heat losses and an intermittent operation of the process. The maximum thermal efficiency of carbonisation and gasification would be attainable in a process of internal heating by partial combustion of the fuel under the influence of a regulated mixture of oxygen and steam. The minimum heat losses corresponding, for processes of carbonisation and complete gasification under conditions postulated, are estimated at 2.33% and 5.09% respectively of the heating power of the coal treated. These heat losses correspond with a thermal efficiency of gas production exceeding 90%, even when the fuel for steam raising is deducted. The quantities of oxygen required are small relative to the volumes of gas produced, and while financial conditions are at present prohibitive, the claims of Claude and Jefferies and Norton (*cf.* J., 1919, 122r) indicate that in the near future the cost of oxygen may no longer prove an obstacle to its application to gas manufacture. Its application would apparently promote economy both in manufacture and utilisation of gaseous fuel, especially for high temperature work.—H. J. H.

Coal; Gasification of — in rotary furnaces. E. Roser. *Stahl u. Eisen*, 1920, 40, 741–747.

MANY of the lighter hydrocarbons are destroyed in the high-temperature zone of a gas producer and in order to recover bituminous constituents, a rotary retort was constructed, similar to a rotary cement kiln, in which a semi-coke was produced which could be subsequently gasified. The tube of the kiln was 24 m. long and 2.5 m. diameter. From 1 ton (metric) of raw coal the average yield of water-free tar was 10%, with 3.0% of crude light oils, and 150 cub. m. of gas containing CO, 6.3%, unsaturated hydrocarbons 10.6, O₂ 2.0, CO 4.6, CH₄ 64.6, N₂ 11.9%, H₂ nil. The amount of semi-coke, after deducting that required for heating the retort, was 650 kg. The thermal efficiency of the process is given as about 90%. The coke can be briquetted very easily, only a small quantity of pitch being required. The total heating value of

the gas from 1 ton of gas coal by the new method is nearly one-sixth less than that of the gas obtained from the same coal in ordinary gas producers, but there are obtained as by-products 30 kg. of light oils, 30 kg. of motor oils, 35 kg. of pitch, and 20 kg. of heavy oils and paraffin.—A. G.

[Gas] mains, services and meters; Internal corrosion of —. J. G. Taplay. Report of Life of Gas-meters Joint Committee, *Inst. Gas Eng.*, June, 1920. *Gas J.*, 1920, 150, 583–587.

THE previous conclusions as to the nature of the corrosive processes (J., 1919, 524a) were confirmed by the results of the examination of 40 more samples of liquid and solid deposits taken from distribution systems. Oxides of iron found are corrosion products and do not originate from purifier boxes. Moisture is essential to all corrosion processes, carbonyl formation excepting, and hence a preliminary compression of the gas is recommended, with separation of liquid, followed by expansion to reduce moisture content below the dew point. Protective paints tried prevented corrosion, but were not permanent in presence of benzene. Galvanising was ineffective, but tinning would be satisfactory if commercially feasible. Iron coated with lead, or "Armco" metal (iron coated with an alloy of Pb 80:Sn 20%), or aluminium showed considerable resistance to the usual corrosive agents. The desirability of careful purification of gas especially from hydrocyanic acid is emphasised. The corrosive agents may be classified under six headings in order of destructive importance, *viz.*, hydrocyanic acid; carbon bisulphide with ammonia; oxygen; carbon dioxide; sulphur dioxide; carbon monoxide, forming carbonyls.

—H. J. H.

Gas; Relative efficiency in use of different grades of —. Third Report of Research Sub-Committee of Gas Investigation Committee of *Inst. Gas Eng.*, June, 1920. *Gas J.*, 1920, 150, 592–603.

THE report deals with tests of the variation of efficiency with quality of gas when used in the normal upright incandescence mantle burner and in the gas fire. The qualities were varied by the separate addition of nitrogen, carbon dioxide, air, and water-gas to a high-grade coal gas, so that the influence of a single diluent on a combustible mixture of invariant composition could be determined.

Lighting tests.—An arbitrary minimum standard of satisfactory behaviour was defined by the dual requirement of a maximum candle-power of 70 c.p. for the low-pressure upright mantle burner with a thermal efficiency of not less than 30 c.p. per 1000 B.Th.U. of gas burnt. With straight coal gas the air requirement was so large that only by careful regulation of well designed appliances was it possible to secure the aeration necessary to attain the best possible efficiency. As a result of the reduction of air requirement the addition of a limited quantity of inert constituents has not the deleterious effect that might be anticipated. When nitrogen alone was added to straight coal gas the fall in efficiency was negligible at comparable rates of combustion until 25% was present and until 35% of nitrogen was present the above standard was maintained. The addition of 10.5% of carbon dioxide sufficed to depress the efficiency below the standard. The effects of nitrogen and carbon dioxide were apparently additive and thus it is only for small percentages that an equivalence as inerts can be assumed. Each 1% of nitrogen depressed the illuminating power by 0.38–0.52 c.p., whereas 1% CO₂ caused a fall of 1 c.p. The dilution of coal gas with air up to 20–30% had no influence on the illuminating power and thermal efficiency of the mantle, and even up to 40% the standard was maintained. Thus in reckoning inert constituents, for this purpose no account need be taken

of oxygen and its atmospheric complement of nitrogen. In addition to flame temperature, size and shape of flame relative to the mantle are important. The effect of inerts at high dilution affects both factors and the benefits of large additions of water-gas due to a rise in flame temperature are nullified by the alteration to the shape of the flame. The proposed standard was, however, attained by all mixtures containing up to 50% "blue" water-gas.

Gas fire tests.—The alteration, if any, of the percentage of heat radiated (radiant efficiency) when gas mixtures, of quality varied as above, were supplied to a gas fire fuel was examined. The fire used though not of the most efficient type was chosen as being capable of regulation over the whole range of gas mixtures from 600 to 140 B.Th.U. per cub. ft. The radiant efficiency did not suffer by dilution of straight coal gas with air until the calorific value of the mixture fell below 350 B.Th.U. per cub. ft. gross. No measurable effect was produced by the addition of nitrogen up to 20% (C.V. 500 B.Th.U. gross). No measurable effect was produced by the 300 B.Th.U. The actual fall in radiant efficiency, however, was only from 44 to 40%. At 400 B.Th.U. the efficiency was still 42%, and any depression observed in these experiments was not greater than that resulting from the imperfect aeration of high-grade gas. Carbon dioxide as diluent exerted a greater effect than nitrogen, but need not be considered separately unless more than 5% is present. "Blue" water-gas when added to coal gas actually raised the radiant efficiency slightly.—H. J. H.

Flue-gases; Control of — in mixed firing. W. Ostwald. Stahl u. Eisen, 1920, 40, 516—547.

THE main factors in the interpretation of flue-gas analyses are the quantity of excess oxygen over that theoretically required and the composition of the fuel. "Free" oxygen may be high owing to incomplete combustion. If the ultimate analysis of the fuel is known, the above two factors, in conjunction with the determination of the carbon dioxide and excess oxygen, will suffice for control purposes; but if the composition of the fuel is not known, then a determination of the carbon monoxide content of the gas must be made. If the carbon dioxide content be "a"%, carbon monoxide "b," oxygen "c," and nitrogen "d"%, then the carbon in the flue-gases is $a+b$ (in the gaseous state), the total oxygen is $a+b/2+c$, whilst the excess oxygen is $c-b/2$. With deficiency of air the latter expression is negative, and the two main factors are calculated as excess air = $100(c-b/2)/(a+b)$, and percentage of half-burnt carbon = $100b/(a+b)$. Four examples are given to show the application of these formulæ to mixed firing.—A. G.

Flue-gas analyses; Graphical evaluation of —. H. Meyer. Stahl u. Eisen, 1920, 40, 605—610.

THE author elaborates his arguments on the basis of simple carbon-hydrogen mixtures, and interprets the analyses by means of a Gibbs triangular diagram, plotting percentage oxygen, percentage carbon monoxide, and percentage carbon dioxide, excess or deficiency of air being indicated. Three diagrams are given for solid, liquid, and gaseous fuels, the solid fuel being a coal containing C 75%, H 6%, and O 8%, the liquid fuel benzol, and the gaseous fuel blast-furnace gas of the composition CO, 5.4%; CO₂, 30.8%; H₂, 2.3%; CH₄, 1.2%, and N₂, 60.3%. (Cf. J., 1919, 492A.)—A. G.

Acetylene; Volumetric estimation of —. R. Willstätter and E. Maschmann. Ber., 1920, 53, 939—941.

METHODS of estimating acetylene, based on its reaction with silver nitrate and titration of the acid liberated, are unreliable, since it has proved

impossible to find conditions under which 1 mol. of the gas liberates 2 mols. of nitric acid, the amount of the latter actually set free varying from about 0.5 mol. in alcoholic to about 1 mol. in aqueous solution. The following method gives reliable results: Acetylene, in gaseous form or in solution, is agitated for a few minutes with Hoesvay's reagent (J., 1899, 1158), freshly prepared from copper nitrate, ammonia, and hydroxylamine hydrochloride, and the precipitated copper acetylide is collected on an asbestos filter and washed until the filtrate no longer decolorises N/10 permanganate, care being taken not to allow the precipitate to become dry. The copper acetylide is washed from the filter with about 25 c.c. of a solution of 100 g. of ferric sulphate and 200 g. of concentrated sulphuric acid per litre. The ferrous sulphate formed in accordance with the equation, $C_2Cu_2 + Fe_2(SO_4)_3 + H_2SO_4 = 2FeSO_4 + 2CuSO_4 + C_2H_2$, is estimated by titration with N/10 permanganate. The liberated acetylene does not introduce any complications.—H. W.

Acetylene; Quantitative estimation of — in coal gas and air by means of Hoesvay's reagent. H. Arnold, E. Möllney, and F. Zimmermann. Ber., 1920, 53, 1034—1039.

THE gas is shaken in a separating funnel of about 3 l. capacity with about 20 c.c. of the reagent (J., 1899, 1158) at intervals during 1 hr. The precipitate is collected, thoroughly washed with water containing hydroxylamine, and dissolved from the filter by a little concentrated nitric acid. The filtrate is evaporated to dryness and the residuum ignited and weighed as copper oxide. Test analyses performed with mixtures of acetylene and air show the method to be very accurate, and to be available even when not more than 0.04% C₂H₂ is present. At such dilutions, however, it is necessary to add about 5% of carbon dioxide to the mixture, since otherwise the results are low in consequence of atmospheric oxidation. The process can also be used for the estimation of acetylene in coal gas, from which hydrogen sulphide, if present, must be removed, e.g., by dry copper sulphate-pumice.—H. W.

Petroleum oils; Rapid determination of aromatic hydrocarbons in light —. W. Hess. Z. angew. Chem., 1920, 33, 147—148.

SIXTY c.c. of the mineral oil distillate and about 200 c.c. of 95% sulphuric acid are placed in a 500 c.c. flask having a wide, graduated neck, and 50 g. of a mixture of 70% nitric acid, 1 pt., and 95% sulphuric acid, 2 pts. by weight, are added, drop by drop, from a tapped funnel which passes through a ground-in stopper. The latter also carries a small side tube. During the addition of the nitrating acid the contents of the flask are kept below 10° C. The flask is then filled up to the zero mark with 95% sulphuric acid, a plain stopper is inserted, the contents of the flask mixed and allowed to separate. The unattacked mineral oil separates and the volume is noted; the nitrated aromatic hydrocarbons remain dissolved in the acid mixture. If the sample contains more than 33% of aromatic hydrocarbons, more than 50 g. of nitrating acid will be required, but a large excess should not be used.

—W. P. S.

PATENTS.

Briquette-carbonising furnaces. C. H. Smith. E.P. 125,381, 3.4.19. Conv., 3.1.18.

THE briquettes are carbonised in sloping retorts arranged vertically in tiers, which are separated laterally by heating flues or chambers, the air

supply to which is preheated by means of a recuperator. This is constructed so as to provide alternately arranged series of air ducts and waste gas conduits. Means are provided for collecting the products of carbonisation.—A. G.

Carbonisation and gasification plant or the like [and apparatus for synthetic manufacture of ammonia]. W. E. Davies. E.P. 143,602, 21.2.19.

For the withdrawal of gas or vapour from a retort a withdrawal structure is provided consisting of two perforated walls, the space between which is subdivided by partitions into parallel flues, communicating with an exhaustor which withdraws the gas under suction relative to the pressure in the retort. A rapid fall in pressure is obtained, thus greatly favouring conservation of the products by rapid cooling and withdrawal. The structure may be placed centrally in the retort, and the outside wall of the structure may also form a wall of the retort. The invention may be applied to plant for the production of synthetic ammonia.—A. G.

Coke oven. H. W. Buhler. U.S.P. (A) 1,341,257 and (B) 1,341,258, 25.5.20. Appl., 24.1. and 23.2.17.

(A) A SERIES of vertical combustion flues are arranged alternately with a series of vertical air flues, each member of one series being connected with a member of the other series, thereby forming a series of pairs of combustion and air flues. Connections are made between the upper ends of the members of each pair, and a recuperator is located directly under the apparatus, connections being established between the air passages and the lower ends of the air flues and between the heating passages and the lower ends of the combustion flues. (B) A central vertical burner tube, open at the top, is connected at the bottom with a source of combustible gas, an outer concentric burner having its upper end projecting beyond the inner tube, and being connected at the base with a source of practically inert diluent gas.—A. G.

Gas; Means to generate — from coal and/or the like. J. H. Cortesby and S. T. S. Castelli. E.P. 143,361, 12.4.19.

In apparatus for generating gas from powdered coal by the impingement of a Bunsen flame, and wherein a portion of the gas generated is used for feeding the flame, a common controlling handle is provided whereby the supplies of gas and air to the flame are adjusted simultaneously. If steam is used for the production of producer gas, branch passages connect the outlet pipe for the generated producer gas with the fuel inlet pipe at points between the fuel supply and the generating flame, the rich gas distilled from the falling coal dust being led off separately.—A. G.

Gas producers. W. B. Chapman, Assr. to Chapman Engineering Co. U.S.P. 1,341,044, 25.5.20. Appl., 5.8.15.

THE grate of the producer has a relatively large ash opening, through which the ash is discharged by a rotating mechanism. The grate is constructed of radiating overlapping plates with their overlapping parts in contact with each other, and with recesses between the overlapping parts to provide orifices for the admission of air. A beam sweeps over the grate to remove the ash.—A. G.

Gas producer. E. Dolensky. G.P. 310,174, 22.2.17.

THE lower portion of a gas producer is divided into two chambers by means of partition walls, a revolving grate being provided in each chamber. This arrangement facilitates the removal of ash and clinker, and, further, obviates the necessity of adjusting the cross-sectional area of the producer to meet the requirements for ash removal or of retaining a circular shape to enable the grates to be revolved.—W. J. W.

Coal gas; Purification of —. [Removal of sulphur compounds.] F. W. Berk and Co., Ltd., and J. J. Hood. E.P. 143,641, 23.2.19.

THE crude gas is brought into contact with a bed of high-grade bauxite or ignited magnesite between 200° and 600° C., whereby the sulphur compounds are dissociated, producing hydrogen sulphide, which can be removed in the usual way.—A. G.

Hydrocarbon oils; Apparatus for treating —. R. H. Brownlee. U.S.P. 1,325,927, 23.12.19. Appl., 28.1.18.

THE apparatus comprises two vertical series of drums arranged at opposite ends of a furnace, with inclined treating tubes connecting drums of opposite series, and means for introducing oil into one of the drums and a gas into the lowermost of the treating tubes.

Gasoline or light vapours; Art of and apparatus for cooling and condensing —. A. A. Wehr. U.S.P. 1,340,427, 18.5.20. Appl., 2.7.19.

THE vapour is compressed and part of it is suddenly expanded. The low temperature thus produced is made use of in condensing the remainder of the vapour.—A. E. D.

Distillation of oil; Apparatus for —. S. D. Faust, Assr. to International Gasolene Process Corp. U.S.P. 1,340,532, 18.5.20. Appl., 10.3.19.

OIL is conducted through a continuous coil built in two sections. The lower section contains an inner steam-heating coil, and the upper section contains a coil through which superheated steam is passed to superheat the oil and its distillates.—A. E. D.

Oil-cracking apparatus. W. B. Poole, Assr. to Poole Oil Cracking and Refining Co. U.S.P. 1,340,793, 18.5.20. Appl., 23.12.18.

A RETORT is heated in the lowest of a series of superposed heating chambers. Oil enters the upper end of the retort by a pipe extending through the series of chambers, and the products escape from the still by a pipe which also extends through the series of heating chambers.—A. E. D.

Distillation [of liquid hydrocarbons]; Method of —. E. E. Pershall. U.S.P. 1,341,437, 25.5.20. Appl., 20.2.18.

A LIQUID hydrocarbon is heated and is agitated by currents of live steam until coke is formed.—A. G.

Lubricants; Method of making —. C. H. Bierbaum. U.S.P. 1,340,316, 18.5.20. Appl., 6.10.14.

IMPURE flocculated graphite is mixed with water free from deflocculating impurities. Hydrocarbon oil is added, the mixture is agitated, and separated impurities are removed.—A. E. D.

Pulverulent fuel; Supplying — to furnaces. J. E. Muhlfield. E.P. 143,817, 24.2.19. *Pulverulent fuel; Feeding — to furnaces.* V. Z. Caracristi. E.P. 143,819, 24.2.19. *Pulverulent fuel; Burner for supplying — to furnaces. Feeding fuel or other materials in pulverised form.* V. Z. Caracristi and J. E. Muhlfield. IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood charcoal; Properties of —. A. Pickles. Chem. News, 1920, 120, 301—302.

PROLONGED heating at 900° C. increases the absorptive efficiency of charcoal, an increased absorption of ammonia gas, for example, from 17 to 70 vols., being observed after heating for 9 and 21 hrs. respectively. Treatment of the product with dilute hydrochloric acid removes sulphur and ash and tends to increase the efficiency. Cooling the hot charcoal in air is not advantageous. As a decoloriser, properly prepared wood charcoal (birch charcoal) in fine powder is superior to animal charcoal. The more complex the dissolved compound the more readily is it removed from solution by charcoal, and, conversely, compounds simple in structure are negatively adsorbed, i.e., the solvent is removed by the charcoal. Compounds negatively adsorbed are highly ionised, the metallic element is strongly electropositive and univalent, and the constituent ions have a high mobility. Negative adsorption is particularly marked with the alkali halides, notably at temperatures above 40° C.—G. F. M.

Efficiency of different grades of gas. See IIa.

PATENTS.

Distilling carbonaceous material; Apparatus for —. W. P. Perry. U.S.P. 1,341,517, 25.5.20. Appl., 23.7.18.

CARBONACEOUS material is distilled within a vertical chamber, the inner walls of which are provided with abutments at different heights, which, in conjunction with the walls of the chamber, form spaces for the collection of gas. Openings are formed in the walls of the chamber above the grate for the insertion of rakers. Means are provided for removing accumulated gases from the gas-collecting spaces, and gas and steam may be introduced through openings below the grate. A vertical tube with outlets extending downwards is provided within the chamber for introducing gases generated in the material near the grate into the material under treatment at various levels.

III.—TAR AND TAR PRODUCTS.

Benzene and toluene; High temperature reactions of —. S. F. Dufton and J. W. Cobb. Inst. Gas Eng., June, 1920. Gas J., 1920, 150, 588—591.

BENZENE and toluene at varying partial pressures in atmospheres of nitrogen, hydrogen, or methane were passed over a column of hot coke in a silica tube so as to approximate to conditions obtaining in the carbonisation of coal. The time of contact was 10—15 secs. The gases leaving the tube were cooled to condense liquid and solid products, while the gas was collected for analysis. The principal reaction of benzene was condensation to diphenyl, and it was appreciable at 500° C. in an inert atmosphere. At 750° it was more extensive, and further

condensation to diphenylbenzene commenced. At 920° free carbon was produced. The diphenyl condensation was shown to be reversible $2C_6H_6 \rightleftharpoons C_{12}H_{10} + H_2$, thus accounting for the relative stability of benzene at 800° in an atmosphere of hydrogen or coal gas. In an inert atmosphere toluene exhibited a molecular condensation at 550° giving stilbene and an oil, possibly ditolyl. At 750° the reaction was more extensive and complex, naphthalene, diphenyl, and anthracene being identified in the product. These condensations were inhibited by the presence of an atmosphere of hydrogen which, however, caused decomposition of the toluene by the elimination of the side chain: $C_9H_7.CH_3 + H_2 \rightleftharpoons C_9H_8 + CH_4$. This reaction was shown to be reversible by experiments in an atmosphere of methane. Xylene and cresol in hydrogen yielded toluene and benzene, and thence the decomposition products of these.—H. J. H.

Naphthalene; Thermal analysis of the products of nitration of —. Pascal. Bull. Soc. Chim., 1920, 27, 388—408.

A STUDY of the melting-point curves of the various binary and ternary mixtures of nitronaphthalene, 1,5- and 1,8-dinitronaphthalenes, and 1,3,5-, 1,3,8-, 1,2,5-, and 1,4,5-trinitronaphthalenes. The results are applied to the analysis of the industrial products of nitration of naphthalene. In products containing a percentage of nitrogen corresponding to dinitronaphthalene, points of arrest in the cooling curve noted at 90° C. and 50° C. indicate the simultaneous presence of nitro- and trinitronaphthalene.—W. G.

PATENTS.

Methyl derivatives of arylamino compounds; Production of —. A. Mailhe. E.P. 124,219, 11.3.19. Conv., 21.4.17.

Mono- and di-methylated arylamines are obtained by passing a mixture of the vapours of an arylamine and methyl alcohol over a suitable catalyst, preferably precipitated alumina, at 350°—400° C., condensing the product, and separating the methylated bases from the condensed liquid. The catalyst may be spread on trays arranged in a series of tubes built into a suitable furnace, and when exhausted it can be regenerated by calcination in air. The mixture of mono- and di-methylamines produced by this process may, if desired, be converted entirely into the dimethylated base by passing the vapour, mixed with a further quantity of methyl alcohol, a second time over the catalyst. Examples are given of the preparation of the mono- and di-methyl derivatives of aniline, toluidines, xylydines, and naphthylamines.—G. F. M.

IV.—COLOURING MATTERS AND DYES.

Photographic sensitizers. Barbier. See XXI.

PATENTS.

Dyestuff [; Production of a — from petroleum]. H. A. Frasch. U.S.P. 1,323,263, 2.12.19. Appl., 23.6.17.

THE product obtained by treating petroleum or its distillates with inorganic acids, such as sulphuric acid, e.g., sludge or sludge coke, after suitable treatment to remove acid, is exposed to the action of a halogen in the presence of an oxidising agent, e.g., to sodium hypochlorite solution or *aqua regia*. On neutralising, a precipitate ("petracin B") is formed, and is separated from the solution, which contains a soluble product ("petracin A"). The

oxy-celluloses behave as mixtures of celluloses and their degradation products. In the cases of hydro-celluloses from cotton or from wood, the degradation products are present in amounts varying from about 24 to 36%. Oxycellulose prepared by the action of bleaching powder contains about 60% of pure cellulose and 40% of apparently oxidised hydration products. Sulphite-celluloses contain cellulose-dextrins, either from the original material or formed during the process of boiling; these can be removed by boiling with lime. A variety of cellulose which is practically without reducing power is obtained by the action of boiling milk of lime on sulphite-celluloses or on hydro- or oxy-celluloses. Sulphite wood celluloses lose up to 50% of their pentosan content when boiled with milk of lime, and the methyl content is also diminished, sometimes to a considerable extent; the residue, however, still contains pentosans in very stable combination. Treatment with lime dissolves but little from soda ligno-celluloses, since any cellulose-dextrins which may be present are dissolved during the boiling with alkali. Products which are closely similar to cotton cellulose are readily obtained by the treatment of wood celluloses with boiling milk of lime, and this is particularly the case with bleached sulphite-celluloses. The material is woolly in appearance and touch, and, in the form of paper, has a greater absorptive capacity than the untreated material.—H. W.

Wood; Distribution of certain chemical constants of — over its proximate constituents. W. H. Dore. *J. Ind. Eng. Chem.*, 1920, 12, 472–476.

ABOUT one-half of the furfural-yielding groups in redwood (*Sequoia sempervirens*) are associated with the cellulose, but only a small amount with the lignin; the portion present as true pentosan is hydrolysed and removed during chlorination. The groups yielding acetic acid are associated partly with the cellulose, much less so with the lignin, whilst a small amount appears to be detached from either. The methoxy groups are associated wholly with the lignin.—W. P. S.

Woods; Proximate analysis of coniferous —. W. H. Dore. *J. Ind. Eng. Chem.*, 1920, 12, 476–479.

A SCHEME of analysis described previously (*J.*, 1919, 496 A) is modified in order that the sum of the various constituents shall account for practically all the material of coniferous woods. The determinations made are: loss on drying at 100° C., benzene extract (6 hrs.' extraction), alcohol extract (6 hrs.), cellulose, lignin, soluble pentosans, mannan, and galactan. The alcohol extract is determined on the material already extracted with benzene; cellulose is determined in the extracted material by Sieber and Walter's method (*J.*, 1918, 132 T), and lignin by digestion with 72% sulphuric acid. Soluble pentosans are determined in the chlorination liquor from the cellulose determination, and mannan and galactan on separate portions of the raw material, the mannan being determined by Schorger's method (*J.*, 1917, 1003). In the case of redwood, yellow pine, and sugar pine, the sum of the constituents determined by the above methods amounts to slightly over 100%.—W. P. S.

Nitrocelluloses. Duclaux and Wollman. *See* XXII.

PATENTS.

Vegetable fibres; Treatment of —. Gillett et Fils, Assees. of C. Schwartz. E.P. 136,568, 12.12.19. Conv., 13.12.18.

Raw, bleached, or mercerised vegetable fibres are treated at 0°–25° C. with a solution of cellulose in nitric acid of not less than 65% for not more than

4 hr. without tension, and then washed. The fibres thus coated with nitrated cellulose resemble wool, and may be directly dyed with basic dyes. Denitration is unnecessary. For low-quality fabrics suitable cellulose solutions are prepared by dissolving 30 g. of disintegrated and bleached wood pulp or cotton waste, or 100 g. of hydrocellulose in 1000 g. of 81% nitric acid at 15°–20° C. and adding 112 g. of water, or by treating 70 g. of mercerised cellulose for 2 hrs. with 750 g. of 75% nitric acid, then expressing 460 g. of the acid, adding 500 g. of 92% nitric acid, and diluting with 145 g. of water. For high-quality fabrics a solution of 50 g. of mercerised cellulose in 1000 g. of 83% nitric acid, subsequently diluted with 250 g. of water, is used. The treatment does not impair the strength of the fabric and print effects may be obtained.—A. J. H.

Textile fabrics; Waterproofing —. L. Meyer. G.P. 309,131, 24.5.18.

In waterproofing fabrics with soap, and subsequent treatment with fats and solutions of metal salts, soap is economised by using it in the form of a lather.—C. A. M.

Balloon fabrics; Increasing the impermeability of — to gas. W. Deutsch. G.P. 309,201, 14.11.16. Conv., 11.11.16.

BALLOON fabrics are impregnated with aqueous solutions or suspensions of soaps, fats, fatty acids, or fatty acid salts, and then, with or without subsequent treatment with aluminium acetate, dried in the air at the ordinary or higher temperatures.—C. A. M.

Fibrous material for surgical dressings. S. von Kapff. G.P. 318,517, 26.7.17.

THE material consists entirely or chiefly of wool which has been treated with chlorine. The wool may, for example, be treated for a few minutes in a cold bath of sulphuric acid of 1°–3° B. (sp. gr. 1.007–1.021), and then repeatedly for periods of 15 min. in a clear solution of bleaching powder (1 l. of solution of sp. gr. 1.043 per kg. of wool), and subsequently rinsed in water. The chlorinated wool can absorb much more moisture than cotton without feeling wet, and even when thoroughly saturated with liquid remains open, loose, and permeable to air.

Acidity of sulphite liquor; Apparatus for regulating the — and other like purposes. J. B. Crandon, Assr. to Crandon Manufacturing Co. U.S.P. 1,311,361, 25.5.20. Appl., 12.8.18.

AN electric current is passed through the solution and through an electric heating device, thereby operating a device for controlling the addition of a neutralising agent to the solution.—A. J. H.

Paper, cardboard, and the like; Production of a paste for the manufacture of —. C. O. Lottero. U.S.P. 1,311,991, 1.6.20. Appl., 31.8.18.

PAPER pulp is obtained from the roots of the lucerne (*Medicago sativa*) or similar plants by drying, sifting, washing, macerating for about 8 days in the presence of lime, grinding, and mixing.—A. J. H.

Paper, fabrics, etc.; Sizing and impregnating — with glue, casein, etc. Exportingenieur für Papier- u. Zellstofftechnik. G.P. (A) 291,228 and (n) 291,229, 3.7.15.

(A) AN addition of sodium hydroxide (2%) or of lactic acid (30% on the weight of the dry glue) is made to glue solution to increase its penetrative power. (n) Methylformamide (about 2% on the dry glue) is used to harden the glue or casein.—C. A. M.

Paper; Sizing of — by means of mixtures of colloidal substances with water-glass. M. Müller. G.P. 317,948, 20.7.17.

THE sizing agents are precipitated partly or completely by the addition of acids or acid salts, especially aluminium compounds, prior to the addition of the mixture to the paper stock. Substances which increase the stability and have filling or sizing properties, or filling materials or colouring matters in the form of emulsions, may also be introduced.—C. A. M.

Paper; Manufacture of dense, strong —. C. G. Schwalbe. G.P. 319,826, 27.4.18. Addn. to 303,498.

PASTY materials, obtained by treating waste paper or cellulose with chlorine and water, followed by grinding with water, are incorporated with paper pulp.—W. J. W.

See also pages (A) 517, *Alkali silicate* (G.P. 318,516); *Aluminium compounds* (G.P. 319,420 and 319,521). 519, *Acetylcellulose films* (G.P. 297,955). 524, *Grain* (G.P. 318,701). 529, *Pyroxylin solvent* (U.S.P. 1,341,710).

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Tussar silk; Black dyeing of —. J. P. Srivastava. J. Sec. Dyers and Col., 1920, 36, 173—177.

IN the degumming of genuine Tussar silk the loss of weight with boiling water is 15—18% and by treatment with alkalis and acids about 20%. Silk degummed with boiling water alone gave the best dyeing results with all classes of dyestuffs. Direct, acid-chrome, and logwood colours gave satisfactory results. With acid dyes the lustre was impaired, whilst sulphur blacks gave very poor dyeings having no lustre.—A. J. H.

Dyeing "polished" cotton thread. A. Winter. Färber-Zeit., 1920, 31, 121—123.

THE yarn is treated before dyeing by the usual methods. Yarn dyed with natural dyes has a pleasing bloom and "handle" and soft tone. For black, logwood used with fustic on an iron or copper mordant is especially suitable. Direct black dyes can also be used with logwood, tannin, and iron acetate. The dyed cotton is finished by treatment with a paste made thus: 300 g. of "diastafor" is allowed to react with 20 kg. of potato starch and the action stopped at a suitable point by heating; 500 g. of wax, 250 g. of paraffin, 250 g. of tallow, and 300 g. of borax are added, the mixture heated, diluted to 250 l., and suitably coloured.—A. J. H.

PATENTS.

Dye jigs. J. Gaston and H. Rushton. E.P. 139,971, 10.6.19.

IN an ordinary dye jig a cloth-stretching roller, such as is used in calendering machines, is provided at each side of the trough and rotated in the desired direction against the cloth by means of a chain drive or equivalent gearing from the large roller at the opposite side.—L. L. L.

Scouring, washing, crabbing, and otherwise treating textile fabrics; Machine for open —. J. Yates and H. Wilkinsen. E.P. 143,431, 21.7.19.

THE fabric passes through the machine by way of overhead stretching and guide rollers, down an inclined bed, through a front trough, then through a rear trough, and afterwards between a constantly driven drum and an adjustable pressure roller situated over the rear trough, which is provided

with perforated steam and water pipes and contains the liquid with which the fabrics are treated.

—A. J. H.

Textiles, skins, and other materials; Process and apparatus for treatment [impregnation] of — [with liquids under vacuum]. P. M. Quas-Cohen, M. N. Drucquer, and L. A. Levy. E.P. 143,443, 5.8.19.

THE materials are passed through a seal consisting of the liquid with which they are to be treated, upwards through a column of the same liquid (the height depends on atmospheric pressure), into a vacuum chamber, and then downwards through the same column and seal.—A. J. H.

Silk; Process of dyeing raw —. E. L. Maupai. U.S.P. 1,332,675, 2.3.20. Appl., 23.5.19.

UNTWISTED silk threads are treated to harden the natural gum or ceraceous matter, then dyed, and the gum or ceraceous matter subsequently removed.—L. L. L.

Yarn-treating mechanism. W. J. Goings. U.S.P. 1,333,481, 9.3.20. Appl., 8.11.17.

LIQUID is forced through a tubular yarn rack with yarn supports, which conduct the liquid from the rack. Detachable means are provided to prevent the yarn from floating off the supports.—L. L. L.

Dyeing of fibres and fibre products; Process and apparatus for electrical treatment in the — and the dyestuffs and the product resulting therefrom. J. E. Bloom. U.S.P. 1,333,700, 16.3.20. Appl., 3.12.17.

FIBRES and fibrous material are treated in solutions or suspensions of dyestuffs in suitable liquid media, under the influence of an alternating current.—L. L. L.

Yarn-treating mechanism. W. J. Goings. E.P. 142,771, 8.3.20.

SEE U.S.P. 1,333,481; preceding.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Arsenic in sulphuric acid; Rapid method for determination of —. A. A. Kohr. J. Ind. Eng. Chem., 1920, 12, 580—581.

TO determine arsenious acid, 20 g. of acid is diluted with water, and methyl orange added. To the solution is added a saturated solution of sodium carbonate until only a very faint pink colour persists, after which 2 g. of powdered sodium bicarbonate is added. The solution is diluted to 250 c.c. with water and titrated with N/10 iodine and starch, a blank titration being made. For the estimation of quinquivalent arsenic 20 g. of acid is heated at 105°—110° C. for 1 hr., diluted with a small amount of water, and saturated sodium carbonate added in slight excess, phenolphthalein being used as indicator. The solution is boiled and filtered. To the filtrate are added 3 g. of powdered sodium bicarbonate, 150 c.c. of concentrated hydrochloric acid slowly with agitation, and 1 g. of potassium iodide, air being excluded. After agitation and standing for 5 mins. the liberated iodine is titrated with N/10 thiosulphate and starch. Copper salts interfere with the determination, but are usually negligible. If present in quantity, the amount of potassium iodide should be increased. (Cf. J.C.S., Aug.)—W. J. W.

Nitrogen oxides; Absorption of — by dilute nitric acid. E. K. Rideal. J. Ind. Eng. Chem., 1920, 12, 531—538. (Cf. Partington and Parker, J., 1919, 75 t.)

THE absorption of nitrogen peroxide by dilute nitric acid in presence of air follows a uni-mole-

cular law. In aqueous solutions, as in the weak acid towers, the process is one of physical solution and depends on the partial pressure of the nitrogen peroxide; it proceeds most rapidly at high temperatures. In strong acid solutions, on the other hand, the reaction is a chemical one, and the rate of absorption depends on the concentration of the gas, absorption proceeding most rapidly at low temperatures. The point of inversion, i.e., where absorption is independent of temperature, is at about 10% nitric acid concentration. The limitation of nitric acid strength to 61% in towers is due to reduction by nitrous anhydride, the equilibrium constant K at this stage being 0.815. By limiting the amount of water vapour, and agitation with oxygen, concentrations above 61% are obtainable, the condensed acid separating into two layers of different strengths. Strong nitric acid may be produced by suitable refrigeration of a mixture of nitrogen peroxide, water vapour, and oxygen.

—W. J. W.

Hydrochloric acid; Production of — from chlorine and water. H. D. Gibbs. *J. Ind. Eng. Chem.*, 1920, 12, 538—541.

Is the formation of hydrogen chloride from chlorine and water, with charcoal as a catalyst, at low temperatures, influential factors are temperature, relative concentrations of water and chlorine, and the nature of the charcoal. Curves are plotted for temperatures of 0°, 12°, 25°, and 37.5° C., and for ratios of water to chlorine of 0.1:1; 3.1:1; 6.2:1; and 12.4:1. With two varieties of charcoal, a maximum hydrogen chloride production of 31%, falling to 18%, in 800 mins. was obtained in one case, as compared with 26%, falling to 7%, in the other. (*Cf.* J.C.S., Aug.)—W. J. W.

Sodium sulphate; Manufacture of — without sulphuric acid. II. G. Pollitz. *Chem.-Zeit.*, 1920, 44, 413—414.

THE Hargreaves-Robinson process (J., 1919, 814A) is principally used in works which also manufacture bleaching powder. There is complete utilisation of the by-products from all the chemicals used, only calcium carbonate, which can again be brought into the circuit, being left. The extension of the process depends upon discovery of new methods of utilising hydrochloric acid in place of sulphuric acid. In a recent process phosphates are decomposed by hydrochloric acid, the hygroscopic properties (due to calcium chloride) of superphosphates thus manufactured being eliminated by the addition of a small amount of a sulphate.—C. A. M.

Ammonium sulphate; Absorption of moisture by, and caking of —. J. T. Sheard. *Gas World*, 1920, 72, 512—513.

AMMONIUM sulphate will absorb moisture from a damp atmosphere to an unlimited extent, whether it contains free acid or not. By exposure to dry air a sample containing 0.5% free acid and 3.5% moisture was dried to 0.3%, while the moisture in material containing 0.16% free acid was reduced from 0.4% to 0.1%. Both neutral and acid samples, which have been allowed to absorb moisture, cake when again dried. Results obtained after treatment with ammonia to remove pyridine (J., 1920, 332A) showed a difference as regards moisture absorption of degree only from that of untreated samples, and caking occurred after drying the treated samples. Neutralisation of ammonium sulphate with alkalis may precipitate traces of iron in a form unassimilable by soils.—W. J. W.

Ammonium phosphates; Solubility of mono- and di- —. G. H. Buchanan and G. B. Winner. *J. Ind. Eng. Chem.*, 1920, 12, 448—451.

MONOAMMONIUM phosphate: 100 grms. of a saturated solution between 3° and 90° C. contains

18.0+0.455t g. of the salt. Diammonium phosphate: 100 g. of a saturated solution between 10° and 70° C. contains 36.5+0.213t g. of the salt.

—W. P. S.

Sodium hypochlorite; Formation and decomposition of —. F. Giordani. *Rend. Accad. Sci. Fis. Mat. Napoli*, 1919, [iii.], 25, 138—153.

THE formation of hypochlorite from chlorine and sodium hydroxide is accompanied by dilatation, which must be allowed for in calculating the amount of sodium hydroxide required to give a hypochlorite solution of definite titre. Perfectly neutral sodium hypochlorite solution rapidly decomposes, and in practice it is most convenient to stop the action of the chlorine when the concentration of the free sodium hydroxide reaches 1.5%. (*Cf.* J.C.S., Aug.)—T. H. P.

Ferrocyanides; Recovery of — from spent oxide. G. Grube and B. Dulk. *Z. angew. Chem.*, 1920, 33, 141—144.

THE material investigated by the authors gave on analysis: 7.8% $K_4Fe(CN)_6 \cdot 3H_2O$; 0.25% NH_4CNS ; 0.71% NH_3 (free); 1.7% NH_3 (combined); 34.34% S; and 26.3% H_2O . By treatment with slaked lime and subsequent washing with water calcium ferrocyanide is obtained. The yield increases with the quantity of lime up to a maximum with 10%, beyond which it diminishes owing to the formation of an almost insoluble double salt $2CaFe_2O_4 \cdot Ca_4Fe(CN)_6 \cdot xH_2O$. The most favourable temperature for the reaction is 50° C. Below this the reaction velocity is too slight, while at higher temperatures thiocyanate is produced and the yield of ferrocyanide rapidly diminishes between 70° and 80° C. The lixiviated mass may retain 1—2% of insoluble ferrocyanide produced by interaction of ferric hydroxide, calcium hydroxide, and calcium ferrocyanide and the formation of the double salt referred to. This salt may be decomposed by means of hydrogen sulphide and the yield of ferrocyanide correspondingly increased. A similar advantageous effect is obtained by air blowing.

—W. J. W.

Chlorides; Titration of certain — with silver nitrate, using potassium chromate as indicator. H. W. Bolam. *Chem. News*, 1920, 120, 292.

BARIUM and other elements which yield chromates less soluble than silver chromate interfere with the titration of a chloride unless the quantity of potassium chromate added is more than sufficient to precipitate the barium etc. which may be present.

—W. P. S.

Arsenites of lithium and potassium. F. A. H. Schreinemakers and W. C. de Baat. *Rec. Trav. Chim.*, 1920, 39, 423—428.

LITHIUM forms one arsenite, $LiAsO_2$, and potassium forms two arsenites, K_2AsO_3 and $K_4As_2O_6 \cdot 12H_2O$, all of which are soluble in water without decomposition.—W. G.

Carbon monoxide; Electromotive activity of —. K. A. Hofmann. *Ber.*, 1920, 53, 914—921.

IN an open circuit carbon monoxide reacts with alkali hydroxide in the presence of copper, to yield carbonate, very little formate, and mere traces of oxalate and hydrogen; in a closed circuit the hydrogen is oxidised to water by the oxygen liberated at the opposite pole. (*Cf.* J.C.S., Aug.)

—H. W.

Catalysis of oryhydrogen gas by palladium mixed crystals. G. Tammann. *Z. anorg. Chem.*, 1920, 111, 90—96.

EXPERIMENTS were made with palladium-silver and palladium-gold alloys, containing from 0 to 100% Ag and Au respectively, to determine the influence of the composition of the alloy on the temperature

at which catalysis of a hydrogen-oxygen mixture (prepared by the electrolysis of caustic soda solution) commences and, on cooling, ceases. The catalyst in each case was in the form of thin wire, wound in a close spiral. With pure palladium catalysis started at 145° – 163° C., and ceased at 35° – 50° C. With increasing silver content, in the Pd-Ag series, both temperatures rose slowly up to 80% Ag, at which point there was a sudden rise to 370° – 380° C. (commencement of catalysis) and 270° – 276° C. (cessation of catalysis). In the Pd-Au series there was little change from 0 to 70% Au, then a rapid rise in the limiting temperatures from 70 to 100% Au. The temperature at which catalysis starts depends on the rate of distribution of heat through the catalyst and hence, to a marked degree, on the form of the catalyst. With a wire spiral catalysis begins at a lower temperature than with a compact mass of wire. (Cf. J.C.S., ii., 422.)
—E. H. R.

Bromine chloride; its combination with ethylene. M. Delépine and L. Ville. Comptes rend., 1920, 170, 1390–1392.

THE behaviour of a solution of chlorine in bromine towards ethylene, the main product being chlorobromethane, is given as strong evidence in favour of the existence of a bromine chloride.—W. G.

Sulphur; Detection of arsenic in —. H. S. and M. D. Davis. J. Ind. Eng. Chem., 1920, 12, 479–480.

A METHOD proposed by Schaeppi (extraction of arsenic sulphide from the sulphur by means of hot dilute ammonia and determining the arsenic indirectly by weighing the silver sulphide produced when the neutral solution is treated with silver nitrate) is untrustworthy, owing to the fact that sulphur is appreciably soluble in ammonia and yields a precipitate of silver sulphide. Reliable results are obtained when the sulphur is oxidised with bromine and nitric acid and the residue tested by the Gutzeit method.—W. P. S.

PATENTS.

Sulphuric acid; Method of producing and purifying —. P. Haeseler, Assr. to The Liberty Laboratories, Inc. U.S.P. 1,341,462, 25.5.20. Appl., 25.9.18.

A SUBSTANCE containing sulphur dioxide is allowed to react with a reducible compound of selenium, containing oxygen, access of free oxygen being prevented.—W. J. W.

Sulphuric acid; Process of making —. E. L. Larison. U.S.P. 1,342,024, 1.6.20. Appl., 25.8.19.

GLOVER tower gases are passed through a series of packed towers in which the most favourable temperature is maintained by circulation of weak acid, whereby the sulphur dioxide is completely oxidised.
—W. J. W.

Hydrogen and nitrogen [for synthesis of ammonia]; Manufacture of mixtures of —. J. Harger. E.P. 142,874, 23.11.17.

COAL of high nitrogen content and containing little sulphur is mixed with a paste of iron oxide and calcium carbonate and coked in the upper portion of a double producer. Below this is a gas producer proper, fed with hot coke from the preliminary producer, into which steam, air, and oxygen are blown, the temperature being kept at 650° – 850° C. The gaseous mixture of hydrogen, nitrogen, carbon monoxide, and carbon dioxide is passed over limestone or magnesia to remove sul-

phur, mixed with steam, and passed over a catalyst, such as iron oxide, whereby the carbon monoxide is converted into dioxide, and carbon bisulphide into hydrogen sulphide, which is later removed by passing over heated iron oxide, traces of carbon monoxide being eliminated by addition of air and employment of a catalyst (J., 1919, 577 A). After compression of the mixed gases to condense steam they are blown into towers, in which they are treated with ammonia and water, the carbon dioxide being converted into ammonium bicarbonate. Ammonia and calcium sulphate may be used as absorption mediums. The gases are freed from oxygen in a tower, compressed to 100–150 atm., and the water separated utilised to remove traces of ammonia from the circulating gases in the synthetic ammonia plant. The mixed gases are washed, passed through caustic alkali solution, and then solid caustic alkali, heated, and conducted to the plant for production of synthetic ammonia.
—W. J. W.

Ammonia; Synthetic production of — [and estimation of ammonia in the gases]. E. K. Rideal and A. G. Tarrant. E.P. 143,341, 10.3.19.

THE gases are passed into an absorption apparatus, through which distilled water circulates at a fixed rate, by means of a control valve and a flow meter; the latter may consist of a constricted tube the ends of which are in communication with a liquid such as aniline, the rate of flow being indicated by an index scale. The ammonia solution from the absorber flows through an electrolytic cell with suitable electrodes in which its electrical conductivity is measured. The rates of flow of the gases and of the absorbent must be adjusted as necessary.
—W. J. W.

Sodium monochromate; Transforming — into bichromate or chromic acid. Soc. Ind. de Prod. Chim. E.P. 131,289, 6.8.19. Conv., 13.8.18. (Cf. J., 1919, 253 A.)

CARBON dioxide is passed into sodium monochromate solution at 30° C., the precipitated sodium bicarbonate is separated, and the filtrate is boiled and treated with slaked lime to convert the sodium bichromate into calcium chromate, which is separated, washed, centrifuged, and agitated with sodium bisulphate solution at 70° C. The sodium bichromate formed may be separated from the calcium sulphate and converted into chromic acid by means of sodium bisulphate or sulphuric acid.—W. J. W.

Ammonium and sodium sulphates; Recovering — from coke-oven and like gases. Soc. Ind. de Prod. Chim. E.P. 136,833, 27.9.18. Conv., 27.5.18.

AMMONIA is absorbed from the gases in a solution of sodium bisulphate to obtain a double sodium-ammonium sulphate, $\text{Na}_2\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ (or a salt of about the same composition). The solution is heated to boiling to obtain anhydrous sodium sulphate, which is separated from the ammonium sulphate by hot filtration.—A. G.

Potassium sulphate; Manufacture of —. Fabr. de Prod. Chim. de Thann et de Mulhouse. E.P. 137,296, 29.12.19. Conv., 28.12.18.

POTASSIUM bisulphate and potassium chloride, ground so as to pass through a sieve of 50–80 meshes per linear inch, are intimately mixed and heated to 300° C., at which temperature the hydrogen chloride may be condensed free from sulphuric acid. Water may be added to the mixture before introducing it into the furnace. The product contains very little chloride. By using 3–5% excess of potassium bisulphate and heating the mass after the first calcining to a temperature of 700° C., with condensation of the sulphuric acid evolved, potassium sulphate entirely free from chloride is obtained.—W. J. W.

Sulphur dichloride; Production and utilisation of —. W. J. Pope and C. T. Heycock. E.P. 142,879, 17.5.18.

THE employment of 1% by weight of finely powdered absorbent charcoal as a catalyst greatly facilitates the reaction between chlorine and sulphur monochloride, and similarly, when sulphur dichloride is subjected to conditions which lead to its decomposition into chlorine and the monochloride, re-combination is facilitated by similar means.—G. F. M.

Sulphur chloride; Process for making —. R. E. Gegenheimer and M. Mauran, Assrs. to The Mathieson Alkali Works (Inc.). U.S.P. 1,341,423, 25.5.20. Appl., 28.12.18.

A DEEP bath of sulphur chloride in contact with molten sulphur is treated with free chlorine, and the temperature of the mixture and of the reaction products is regulated so that the sulphur-bearing constituent of the products consists almost solely of sulphur monochloride.—W. J. W.

Thorium; Recovering — from monazite sands. O. N. Berndt, Assr. to Lindsay Light Co. U.S.P. 1,323,735, 2.12.19. Appl., 27.6.17.

MONAZITE sand is heated with concentrated sulphuric acid first until decomposed, and then for a long time at 250°–300° C. until the thorium is converted into a crystalline compound, $\text{Th}(\text{PO}_4)_2 \cdot \text{SO}_4$, insoluble in dilute sulphuric acid. The other rare earths form soluble compounds.

Magnesia; Manufacture of —. E. E. Dutt, Assr. to P. C. Dutt. U.S.P. 1,325,932, 23.12.19. Appl., 18.10.18.

A MAGNESIUM compound containing calcium and iron is dissolved in hydrochloric acid, the solution treated with an alkaline-earth oxide or hydroxide to precipitate iron and other similar impurities, then evaporated to dryness, and the residual mixture of chlorides treated with steam at 450°–700° C., after which the calcium chloride is dissolved in water and separated from the magnesia.

Magnesium from dolomite; Process of separating —. A. M. Mitchell, Assr. to Mitchell and Grenelle, Inc. U.S.P. 1,340,905, 25.5.20. Appl. 20.1.19.

PULVERISED dolomite is mixed with an alkaline hydroxide which does not react to form a compound with the calcium.—W. E. F. P.

Potash reclaiming. H. W. Charlton. U.S.P. 1,341,110, 25.5.20. Appl., 18.8.19.

GREENSAND is heated with ferrous chloride.
—W. E. F. P.

Sulphur dioxide from gases; Method of and apparatus for recovering —. A. H. Eustis. U.S.P. 1,341,114 and 1,341,115, 25.5.20. Appl., 14.4. and 16.7.19.

MATERIAL containing sulphur dioxide is heated in an extractor in which a partial vacuum is maintained by means of a pump. The sulphur dioxide extracted is passed through the pump, the temperature of the latter being so regulated that the temperature of the gas in immediate contact with it is raised above the dew point with respect to the contained liquid.—W. E. F. P.

Sulphur dioxide solution; Method of obtaining a concentrated —. N. C. Christensen, Assr. to J. E. Barlow, and Big Indian Copper Co. U.S.P. 1,341,734, 1.6.20. Appl., 3.7.17.

IN processes in which a concentrated sulphur dioxide solution is deprived of part of the sulphur dioxide and caused to absorb it later, losses of sulphur dioxide are made good by causing the weakened solution to absorb the weak replacement

sulphur dioxide, the strong solution so obtained being caused to absorb the relatively strong sulphur dioxide gas previously taken from the solution.

—W. J. W.

Sodium silicate; Process of dissolving —. E. A. Taylor, Assr. to Grasselli Chemical Co. U.S.P. 1,341,288, 25.5.20. Appl., 10.10.17.

THE solvent is passed over and through an excess of the silicate and heated by means of an inert gas.

—W. E. F. P.

Alkali silicate solutions; Increasing the adhesive power of —. W. Dahse. G.P. 318,516, 23.8.18.

SOLUTIONS of alkali silicates become very viscous when treated with solutions of zinc and cadmium salts, and the product may be used as an adhesive for paper, cardboard, wood, leather, etc.—A. J. H.

Titanium-oxygen compounds; Manufacture of —. P. Farup, Assr. to Titan Co. A/S. U.S.P. 1,341,307, 25.5.20. Appl., 25.10.16. Renewed 29.9.19.

TITANIUM hydroxide containing iron and sulphuric acid is treated with sulphuric acid, heated to 300°–500° C. in presence of sodium chloride, and the sintered product lixiviated.—W. J. W.

Chlorine cell [; Electrolytic —]. T. A. Patterson, Assr. to Niagara Alkali Co. U.S.P. 1,341,516, 25.5.20. Appl., 17.2.20.

A CLOSED electrolytic cell is provided with a gas space, with all joints thereof liquid-sealed.

—J. S. G. T.

Electrolytic [chlorine] cell. P. McDorman, Assr. to Electro-Chemical Co. U.S.P. 1,342,336, 1.6.20. Appl., 19.6.19.

AN electrolytic cell comprises a hollow cathode mounted on a base, an anode within the cathode, and a porous diaphragm separating the two. The cell is provided with a head, and a gasket arranged between the head and the anode and cathode prevents the escape of chlorine and the admission of air to the cell.—J. S. G. T.

Electrolytic [hypochlorite] cell. J. Gerstle, Assr. to Electro-Chemical Co. U.S.P. 1,342,378, 1.6.20. Appl., 9.6.19.

AN electrolytic cell comprises separate chambers for the production of chlorine and caustic soda, and an additional chamber wherein chlorine and caustic soda are mixed at the rate of their production, out of contact with the electrodes.—J. S. G. T.

Composition of matter [zirconium compound] and method for producing the same. L. E. Barton, Assr. to Titanium Alloy Manufacturing Co. U.S.P. 1,342,084, 1.6.20. Appl., 4.9.19.

A MATERIAL consisting mainly of zirconium, but also containing nitrogen and (to a smaller extent) carbon, is prepared by heating zirconia-bearing ore with a carbonaceous reducing agent until the zirconium oxide is decomposed, and treating the melt with dilute sulphuric acid.—W. E. F. P.

Aluminium compounds for sizing papers and other purposes; Preparation of —. G. Muth. G.P. (a) 319,420, 14.5.19, and (n) 319,541, 26.11.18.

(A) ALUMINIUM compounds, such as bauxite, clay, etc., in an unburned state, are treated with sulphuric acid or alkali bisulphate solution, in presence of hydrofluoric acid or other fluorine compound. (B) The material may be treated with sulphuric acid or sodium bisulphate, after which the free acid is neutralised by a magnesium compound which may be derived from the precipitation of magnesium sulphate with slaked lime. The product may be used at once, or may be first brought to a solid state by evaporation.—W. J. W.

Hydrogen generators. A. R. Griggs. E.P. 142,882, 9.11.18.

In hydrogen generators comprising an ore chamber and an inner heating space a combustion chamber is constructed at the lower end of this space below the bottom level of the ore, air and reducing gas being led into the combustion chamber through inclined passages. The chamber may be of decreasing cross-sectional area towards the upper end. Efficient mixing of air and reducing gas to give the required degree of combustion at the desired position outside the inner heating space is thus ensured, and the inner metal lining of the ore chamber is protected from overheating and burning.

—W. J. W.

Hydrogen gas manufacture; Process and apparatus for preparing powerful oxidising gases for removing carbon and sulphur deposits in —

Blair, Campbell and McLean, Ltd., D. A. Blair, and J. L. Ferguson. E.P. 143,064, 11.6.19.

THE removal of carbon and sulphur which are deposited in hydrogen retorts and contaminate the gas is effected by periodically passing atmospheric air enriched with oxygen through the retorts. An oxygen-evolving mixture, such as potassium chlorate mixed with manganese dioxide, or with precipitated ferric oxide and kieselguhr, or bleaching powder mixed with cobalt oxide, cobalt sesquioxide, or nickel oxide, is placed in a series of retorts, built in a furnace and heated to 300°–350° C. in the former case and to 80°–85° C. in the latter case. Air is admitted to the bottom of the retorts. The oxidising gas and air are drawn from the top of the retorts into a main by means of an ejector and passed through an alkaline solution to an atmospheric condenser and holder.—W. J. W.

Bromine from brine; Process of extracting —

H. H. Dow, Assr. to The Dow Chemical Co. U.S.P. 1,323,173, 25.11.19. Appl., 24.4.16. Renewed 17.4.19.

BRINE containing bromide is over-oxidised (cf. U.S.P. 1,188,838, J., 1916, 890), and the products of oxidation containing bromine and chlorine are reduced, for example, by treatment with a bromide solution, so that the net result of the oxidation is equivalent to the bromine content.

—W. E. F. P.

Zinc solutions; Purification of — H. L. Sulman and S. Field, Assrs. to Metals Extraction Corp.

VIII.—GLASS; CERAMICS.

Gas retorts; Casting of — Report of the Refractory Materials Research Committee. Inst. Gas Eng., June, 1920. Gas J., 1920, 150, 576–577.

THE casting slip was prepared from Stourbridge fireclay and Stourbridge greg with sodium carbonate or silicate (or a mixture of these) added in sufficient quantity to produce a smoothly flowing mixture without reducing the consistency to such

an extent as to allow the greg to settle. The amount of alkali mixture varies with the nature of the clay and size and proportion of greg, but on an average 0.3%, calculated on the dry weight of the clay used, is sufficient, and this has virtually no influence on the refractoriness of the clay. Solid cylinders, 20 in. in height, were cast from mixtures containing various amounts of greg (up to 175 parts of greg to 100 parts of clay). Vertical sections appeared uniform throughout, showing that the suspended greg did not tend to sink in the slip. Similar uniformity was found in castings made in small saggar moulds with a straight central core if cast under a suitable head. The shrinkage from mould to finished saggar (fired at cone 7) was 4.375%. The surface cracks formed on drying increased with the proportion and coarseness of the greg. They are due to the separation in the mould of an extremely thin layer of fireclay on the surface of the ware, which on drying contracts more than the gregged interior. They do not extend inwards on firing. Retorts of 5 ft. length and of cross-section with outside dimensions 2 ft. 4 in. by 2 ft. were also cast. Determinations of porosities and after-contractions showed the difference in texture at the opposite ends of the cast retort to be negligibly small. The plaster of Paris moulds are estimated to make 50 to 60 casts.—H. S. H.

Silica bricks; Comparative tests of machine-made and hand-made — W. Emery and L. Bradshaw. Gas J., 1920, 153, 577–579.

THE bricks were prepared together from the same materials ((crushed Dinas silica rock bonded with lime), one batch being moulded by hand and the other in a power press. Practically no difference was found in the refractoriness, the refractoriness under load, the reversible expansion at 1200° C., the after-expansion on heating to 1350° C., and the porosity. The apparent specific gravity of the machine-made brick was 1.85 compared with 1.8 for the hand-made brick. The resistance to crushing of the hand-made brick was 28% less than that of the machine-made; the spalling of the hand-moulded brick was greater than that of the machine-made whether determined by the loss in weight after alternately heating and quenching in water or from the decrease in mechanical strength after heating to 600° C. and allowing to cool. The abrasive action of a sand blast on the hand-made bricks was greater than on the machine-made bricks, while the former were less accurate in shape than the latter. Properly prepared machine-made silica bricks are not inferior in any of the laboratory tests tried to hand-made bricks, while in several important respects they are superior.—H. S. H.

Refractory materials; Specific heats of — at high temperatures. I. L. Bradshaw and W. Emery. Gas J., 1920, 150, 579–583.

THE mean specific heats of the materials were measured between 25° and 1000°, 1200°, and 1400° C. by dropping a weighed cylindrical test-piece and its supports, heated to the required temperature in an electric furnace of the Hirsch type into a calorimeter containing water and measuring the rise of temperature with a Beckmann thermometer. The heat communicated by the supports (made from a mixture of china clay and calcined alumina) was about 25% of that conveyed by the whole charge. The values obtained were as follows:—

Temperature. ° C.	Silica brick (96.6% SiO ₂).	Silica brick (84.65% SiO ₂).	Firebrick (59.2% SiO ₂ , 35.3% Al ₂ O ₃).	Zirconia (99% ZrO ₂).
600	0.226	0.228	0.228	0.137
1000	0.263	0.262	0.265	0.157
1200	0.282	0.283	0.284	0.167
1400	0.293	0.295	0.297	0.175

The specific heats of all the materials examined are much greater at high temperatures than at ordinary temperatures.—H. S. H.

Nickel steels; Action of metallurgical additions on the anomaly of the dilatation of —. C. E. Guillaume. Comptes rend., 1920, 170, 1433—1435.

THE effect of additions of manganese (up to about

8%), chromium (up to 10%), carbon (up to 0.6%), and copper (5%) on the dilatation of nickel steels was studied. The additions studied diminish, in every case, the intensity of the anomaly of dilatation in the region of its minimum value. In the case of manganese, carbon, and copper, within a limited region of nickel content, ternary alloys are obtained which have a slightly lower coefficient of dilatation than the binary alloys with the same nickel content. In the case of carbon, if the other constituents are known, measurement of the dilatation of the steel gives a means of fixing the carbon content to within about one ten-thousandth.

—W. G.

Brass; Corrosion of — in dilute electrolytes. J. H. Reedy and B. Feuer. J. Ind. Eng. Chem., 1920, 12, 511—517.

SELECTIVE or electrolytic corrosion is marked by pitting or perforation. The effect of various ions has been investigated experimentally by current potential curves. Marked corrosion is indicated with hydrogen chloride solution; metallic chlorides are less active. Ammonium and calcium chloride solutions are more corrosive than potassium or sodium chlorides. High concentration and elevated temperatures stimulate corrosion, while dissolved oxygen has no effect. In electrolytic mixtures the influence of the various ions is additive. The ions play no specific part in promoting corrosion except in cases where they form complexes of low ionisation, and in the case of the hydrogen ion. Complete corrosion of brass, i.e., of all its components, only takes place in presence of oxygen and high concentrations of solutions and elevated temperatures, which reduce the solubility of oxygen, therefore retard or inhibit corrosion. The influence of the ions is of a specific nature, and may be related to their effect on the solubility of oxygen. Solutions containing chlorides cause marked corrosion, and the ammonium group has a very positive effect. The speed of corrosion is affected by stirring and by the nature of the surface.—W. J. W.

Mercury ores; Assaying —. R. G. Place. Eng. and Min. J., 1920, 109, 1313.

THREE methods are described. In the first, 0.05—0.5 g. of ore, according to richness, is intimately mixed with 0.5 g. of lime in a small mortar, and the mixture transferred to a hard glass tube, bent so that the lower 3 in., in which the charge is placed, is parallel to the upper 6 in. The tube is held in the flame with the mouth slightly downwards, and the lower end is heated to redness for 10 min. The tube is fused off at the bend, a few c.c. of 1% cyanide solution and 2—3 gold balls each weighing 50—80 mg. are put in and the tube gently shaken. The balls are then replaced by fresh ones, this operation being repeated until all the mercury has amalgamated. The balls are washed, dried on blotting paper, then in a desiccator for 10 min., weighed, ignited to volatilise the mercury, and weighed again. The second method is a modification of Eshka's, in which the gold plate is cupped to fit the crucible, the cup being filled with water, which is kept cool by a casserole of cold water placed over it. The third method is a variation of Krickhaus' volumetric method, in which the ore is dissolved in *aqua regia*, the mercury precipitated by stannous chloride, washed by decantation, and dissolved in 4 c.c. of nitric acid. The solution is treated with permanganate till a permanent pink tinge is obtained; this is just discharged with 3% hydrogen peroxide, 5 c.c. of ferric alum indicator added, and the liquid titrated with thiocyanate.—A. R. P.

Film colours of metals. G. Tammann. Z. anorg. Chem., 1920, 111, 78—89.

WHEN a metallic surface of silver, copper, lead, or thallium is exposed to the action of iodine vapour a

thin film of iodide is formed. The rate of increase of thickness of the film was measured by observing the change of colour during exposure of a silver surface to air charged with iodine vapour, and applying well-known laws of optics. The increase in thickness of the film at constant temperature follows a parabolic law, and appears to depend on the rate of diffusion of iodine through the layer of iodide formed. The thinnest film of silver iodide which could be detected corresponded with a thickness of 63×10^{-6} mm., or approximately 90 atomic layers, the corresponding colour being bright yellow. The development of film colours on steel when heated in air appears, from a limited number of observations, to follow the same parabolic law, $y^2 = 2pt$, where y is the film thickness, t the time, and p a constant.—E. H. R.

PATENTS.

Iron and molybdenum; Production of alloys of —. Deutsche Molybdaen-Werke G.m.b.H. E.P. 131,896, 27.8.19. Conv., 25.11.16.

FERRO-MOLYBDENUM or molybdenum steel is produced by the interaction of alkaline-earth salts of molybdic acid with molten iron in the presence of carbon or with steel at about 1700°C .—T. H. Bu.

Iron and steel; Cementation of —. M. L. M. Luttenschlager. E.P. 143,746, 2.7.19.

IRON or steel is heated to 700° — 800°C . in a closed muffle containing a mixture of 1 pt. of potassium ferriocyanide, 1 pt. of potassium chromate or bichromate, 2 pts. of potassium ferrocyanide, and 20—25 pts. of wood charcoal, and then hardened in a solution of sodium chloride and caustic soda, with or without ammonium chloride.—T. H. Bu.

Acid-resisting alloy. A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. 1,333,706, 16.3.20. Appl., 26.7.17.

THE alloy contains Cr 60, Fe 39.2—39.7, and C 0.3—0.8%, the carbon being present as a carbide of chromium and iron.—L. L. L.

Ferrous alloy; Corrosion-resisting —. S. McClure. U.S.P. 1,341,992, 1.6.20. Appl., 31.1.19.

AN iron-copper alloy containing more than 0.5% Cu, but not sufficient to prevent the alloy from being rolled into sheets, is specially suitable for parts of plant exposed to products of combustion of fuel.

—A. J. H.

Rust-proofing compound. W. H. Allen. U.S.P. 1,341,100, 25.5.20. Appl., 18.11.18.

A RUST-proofing compound consists of ferric oxide (1 pt.), ferrous oxide (3 pts.), and phosphoric acid (equivalent of 60 pts. of the commercially pure acid).—A. de W.

Sherardising; Processes and apparatus for —. S. O. Cowper-Coles. E.P. 143,674, 26.3.19.

A ROTARY drum, which is maintained at a constant temperature in a suitable heating apparatus, is divided diametrically into two communicating chambers. When one chamber is being charged with the articles to be coated, the other chamber containing the hot zinc dust is cut off from access of air. After charging, the drum is closed, given a half turn, and the chambers put into communication with each other, so that the hot dust falls on to the articles.—T. H. Bu.

Flotation method. G. D. Van Arsdale and C. G. Maier. U.S.P. 1,325,817, 23.12.19. Appl., 25.9.17.

THE ore pulp is treated with an emulsifying agent (oil), and a true emulsion produced, for example,

by agitation after addition of caustic soda. The mixture is then de-emulsified, e.g., by addition of sodium sulphide, and subjected to flotation. A much better recovery of copper is obtained in this way from certain clayey ores such as Arizona porphyries.

Tin and other ores; Smelting —. J. H. Gray. U.S.P. 1,340,951, 25.5.20. Appl., 18.3.19.

ORES of low volatile metals, e.g., tin, are smelted on the hearth of an electrically-heated furnace in which non-oxidising conditions are maintained, the outlet flues containing material adapted to trap the metal in the fumes.—T. H. Bu.

Solder for aluminium. R. A. Jacobsen. U.S.P. 1,341,508, 25.5.20. Appl., 2.1.19.

AN aluminium solder is composed of Sn 67.60, Zn 16.90, Bi 2.82, Al 1.41, and phosphorus tin 11.27%. —J. S. G. T.

Aluminium; Process for the autogenous welding of —. Chem. Fabr. Griesheim-Elektron. G.P. 319,684, 2.5.17.

SOLUBLE fluorides (e.g., sodium or potassium-sodium fluoride) are added to the alkali halide used as a flux; the slag produced is then readily removed by washing with water. (Cf. G.P. 315,231; J., 1920, 162 A.)—A. R. P.

Platinum and similar metals; Process of extracting from their sands and ores. R. Thayer. U.S.P. 1,341,686, 1.6.20. Appl., 26.6.19.

A CHARGE of ore is mixed with a halogen compound of an alkali metal and heated, and the volatilised metal is collected.—T. H. Bu.

Sintering; Method of preparing fine ores for — and the product thereof. F. A. Eustis. U.S.P. 1,341,890, 1.6.20. Appl., 21.5.19.

THE ore is made into a filter cake, and finely divided fuel is applied to the surface of the cake.—B. M. V.

Light metals; Process and apparatus for the recovery of — from turnings, residues, and ashes. K. Hess. G.P. 318,304, 4.4.18.

THE material is added gradually to a bath of a molten salt contained on the hearth of a furnace, through a feeding device which just touches the surface of the bath, the bath being well stirred by means of a rake after each addition. Openings are provided in the furnace through which the impurities which accumulate on the surface of the bath may be removed. When the salt is saturated with impurities, the charge is poured by tilting the furnace.—A. R. P.

XII.—FATS; OILS; WAXES.

Cottonseed oil; Chemical composition of —. G. S. Jamieson and W. F. Baughman. J. Amer. Chem. Soc., 1920, 42, 1197—1204.

REFINED oil from Sea Island cottonseed consists of the glycerides of myristic (0.3%), palmitic (20%), stearic (2%), arachidic (0.6%), oleic (35.2%), and linolic acids (41.7%). By treatment of the lead salts with ether, a fairly complete separation of the saturated from the unsaturated acids was achieved. By fractionation of the methyl esters of the saturated acids under reduced pressure, and crystallisation of the products of hydrolysis of each fraction, the saturated acids were each isolated and identified.—J. K.

Castor oil and petrol from various sources; Solubility relations of —. W. R. G. Atkins. J. Inst. Petrol. Techn., 1920, 6, 223—228.

SAMPLES of East Indian, Egyptian, and European petrol were miscible with castor oil in all proportions. Fractions distilled at 52° and 90° C. gave critical solution points of 32.2° and 31.6° C., whilst the fraction 104°—144° C. dissolved in all proportions in castor oil. Normal paraffins differ but little in their critical temperatures of solution (47.3°—47.9° C.), whilst benzene, toluene, and pentamethylene are miscible with castor oil in all proportions. The presence of aromatic and naphthene compounds lowers the miscibility temperatures of the paraffins. Variations in the castor oil also affect the critical temperature of solution.—C. A. M.

Fatty acids obtained by the oxidation of paraffins. F. Fischer and W. Schneider. Ber., 1920, 53, 922—925.

PURE paraffin or crude expressed paraffin was heated with dilute sodium carbonate solution in a steel autoclave at about 170° C., whilst simultaneously compressed air was pumped through the mixture. The paraffins were oxidised more rapidly under these conditions than at atmospheric pressure, and the yield of fatty acids was as high as 90% of the paraffin used. The rate of reaction varies with the temperature, and is proportional to the pressure of the air. Iron, manganese, and

copper had approximately equal catalytic effects, but other substances investigated were less active. The highest yields per given time were best obtained by working to secure complete neutralisation of the sodium carbonate solution rather than complete utilisation of the paraffin. The acids formed are true monobasic fatty acids of sp. gr. less than 1 and completely soluble in light petroleum; unlike the commoner members of this series, however, they contain an uneven number of carbon atoms. The following have been definitely identified:— $C_{15}H_{31}O_2$, m.p. 65°—66° C.; $C_{17}H_{33}O_2$, m.p. 58°—59° C.; $C_{19}H_{37}O_2$, m.p. 50°—51° C.; $C_{21}H_{41}O_2$, m.p. 38° C. Examination of a patented process for the oxidation of paraffin by blowing air through the substance heated at 135°—145° C. in an iron vessel in the absence of water showed that the actual products are the acid anhydrides which can be separated from unaltered paraffin by means of acetone.—H. W.

Paraffins; Oxidation of — [to fatty acids etc.]. A. Grün. Ber., 1920, 53, 987—996. (Cf. Kelber, J., 1920, 220 A.)

PURE paraffins, or mixtures such as vaseline or petroleum, are readily oxidised under suitable conditions by air or even by gaseous mixtures containing as little as 1% of oxygen. The statements by various authors that the process can be catalytically accelerated by oxygen-carriers are, in general, erroneous and depend, in part at any rate, on insufficiently extended analysis of the products. Thus, a series of experiments carried out with a paraffin (m.p. 52° C.) at 160° C. showed that metallic oxides such as lime and barium oxide, salts with an alkaline reaction, and certain neutral substances such as carbon and fuller's earth are particularly harmful, whilst acidic substances, such as stearic acid, are, according to the properties of the hydrocarbon used, either helpful or at any rate not markedly inhibitive. If the conditions of reaction are not carefully chosen, one carbon atom after another of the intermediate products can be oxidised away, and the whole series of acids from those of high molecular weight to the volatile acids and ultimately formic acid, or carbon dioxide may be obtained. Particularly when oxygen is used, the action is likely to lead to violent explosions due to the intermediate formation of peroxides. The products of oxidation differ quantitatively and qualitatively according to the conditions of the experiment. When the oxidation is not too vigorous, the product consists of mixtures of waxes with more or less free acid, alcohols, and some unsaponifiable matter. The composition of the mixture of acids depends on factors such as temperature, duration of action, etc., and the product may consist mainly of the series C_{16} to C_{22} or higher or of such in which C_{18} to C_{24} or C_{26} predominate. Hydroxy fatty acids are also formed and are present partly in the form of esters or estolides, whilst unsaturated acids, probably derived from the hydroxy-acids by loss of water, are also found. The unsaponifiable matter consists to a small extent of unchanged paraffin, but chiefly of higher alcohols together with other compounds, probably aldehydes, but possibly also containing ketones. (Cf. J.C.S., Aug.)—H. W.

PATENTS.

Oils, fats, and the like; Treatment of —. G. Calvert. E.P. 143,321, 21.2.19.

OILS or fats are agitated by spraying etc. with glycerin at about 140° C. until free fatty acids and other inedible constituents are esterified into edible glycerides. The treatment may be carried out under pressure or in a current of dry non-injurious gas to remove water, or in the presence

of a catalyst. The oil may also be simultaneously deodorised or hydrogenated.—C. A. M.

Grease; Apparatus for extracting — from organic matter. K. A. Stahlgren and T. L. Shannon. U.S.P. 1,341,523, 25.5.20. Appl., 11.3.19.

GREASE is extracted from organic substances by means of a solvent in a rotary drum provided with an agitator (which also serves as a means of heating) adjacent to the walls of the drum and which is rotated in an opposite direction to the drum.

—C. A. M.

Oils; Manufacture of edible and technical —. Byk-Guldenwerke. G.P. 317,717, 18.5.18.

ALKYL esters of fatty acids are polymerised, with or without the simultaneous action of oxygen or active light rays, or fatty acids, which have been thickened by oxygen or active rays, are converted into alkyl esters. The ethyl ester of linseed oil fatty acids when heated to 300° C. yields a product with iodine value about 100 and a viscosity between that of olive and castor oils.—C. A. M.

Fats; Process of extracting — from moist, granular or pulverulent substances. A. Lorenz. G.P. 319,664, 25.7.17.

THE material is extracted in a closed vessel containing a perforated false bottom by means of a solvent introduced from below. The false bottom rests on a central support, which serves as distributor of the solvent, and is perforated with large holes opening obliquely downwards. The bearing for the axle of the agitator is also constructed in the central support, and is cooled by the cold solvent.—C. A. M.

Copra-drying apparatus. J. D. McCord, Assr. to San Pablo Oil Mills, Ltd. U.S.P. 1,341,655, 1.6.20. Appl., 31.10.17. Renewed 2.1.20.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

PATENTS.

Resins; Process for purifying —. B. T. Brooks, Assr. to The Commercial Research Co. U.S.P. 1,340,873, 25.5.20. Appl., 14.5.18.

RESINOUS material is subjected to the action of the chlorhydrin of a gaseous elefine, the liquid portion separated from any solids accompanying it, and then evaporated to recover resinous material, the distillate being condensed. Steam is passed through the solid material to extract any liquids remaining in it, the extract is concentrated and united with the condensed distillate, and the resultant liquid employed for treatment of a fresh charge of resinous material.—A. de W.

Varnish; Process of manufacturing —. C. H. Bennett. U.S.P. 1,341,103, 25.5.20. Appl., 20.1.19.

A QUANTITY of varnish "body" is cooked remote from a closed blending chamber, then transferred to the blending chamber, and a quantity of solvent introduced. The solvent vapours are led off from the blending chamber by means of vapour pressure, condensed, and returned to the chamber (*cf.* U.S.P. 1,298,159; J., 1919, 428 A).—A. de W.

[*Resinous*] moulded products; *Process of producing —.* L. T. Richardson, Assr. to The Cutler-Hammer Mfg. Co. U.S.P. 1,342,067, 1.6.20. Appl., 6.6.18.

A PHENOLIC substance is mixed with a non-volatile methylene compound in proportions to afford about

one phenol group to one methylene group, and the mixture is heated under anhydrous conditions to form an initial condensation product in which less than half the phenolic substance has combined. This is mixed with a filler, the mass compacted, and the condensation reaction completed by further heating.—B. M. V.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation and depolymerisation. E. Seidl. Gummi-Zeit., 1920, 34, 797—798.

THE beneficial effect accruing to rubber by vulcanisation by the hot process is accompanied by a less marked adverse "depolymerisation" effect, which is masked by the former. Rise in temperature, however, increases the rate of the former change more than that of the latter, so that by vulcanisation at a higher temperature to the same percentage of combined sulphur, the proportion of the depolymerisation effect relative to the beneficial effect is decreased and the product possesses greater strength.—D. F. T.

Rubber membrane; Process of diffusion through a —. H. A. Daynes. Proc. Roy. Soc., 1920, A, 97, 286—307.

THE passage of a gas through a rubber membrane is a simple diffusion process in which the surface resistance is practically negligible. The mean diffusion constant is 11.4×10^{-6} cm. per sec. at 20° C. The absorption coefficient is 0.035 (mean), and this has a low temperature coefficient, 0.5% per 1° C. (*Cf.* J.C.S., Aug.)—J. F. S.

PATENT.

Rubber compounds; Manufacture of —. H. Wade. From Goodyear Tire and Rubber Co. E.P. 143,610, 24.2.19.

SEE U.S.P. 1,301,693 of 1919; J., 1919, 472 A. Other ingredients than barium sulphate can be incorporated in rubber mixings in a similar manner.

XV.—LEATHER; BONE; HORN; GLUE.

Tanning materials; True tanning value of vegetable —. J. A. Wilson and E. J. Kern. J. Ind. Eng. Chem., 1920, 12, 465—469.

TANNIN is defined as that portion of the water-soluble constituents of the material which will precipitate gelatin from solution and which will form compounds with hide fibre which are resistant to washing. To determine the true tanning value of vegetable substances 12 g. of hide powder, of known hide substance content (nitrogen $\times 5.62$), is shaken for 6 hrs., with 200 c.c. of an aqueous solution of the tanning material; if, after this shaking, the solution gives a turbidity with gelatin-salt solution, the operation must be repeated, using less of the tannin solution. The tanned powder is washed with water and squeezed, about 12 washings being required to remove non-tannin substances (ferrie chloride test), then dried at room temperature for 24 hrs., and analysed for water, fat (chloroform extract), and hide substance. The difference between the percentage sum of these constituents and 100 is taken as the percentage of tannin. Analyses of quebracho, oak bark, sumach, etc., by this method and by the official method of the American Leather Chemists' Association show that the latter method may give results in error to the extent of 43—220%.—W. P. S.

Tanning materials; "Modified shake method" of analysis of —. G. Baldracco and S. Camilla. J. Soc. Leather Trades' Chem., 1920, 4, 101—111.

A REPLY to Parker's criticisms (J., 1920, 123A). The results obtained with the official "shake method" are liable to considerable variation (cf. Jedlicka, Collegium, 1916, 557). Non-tannin filtrates obtained from the official method of analysis of certain tanning materials may contain tannins which are not precipitated by the ordinary gelatin-salt reaction, but are precipitated by the gelatin-acetic acid reagent (0.9 g. of gelatin dissolved in 50 c.c. of distilled water on the water-bath and mixed with 10 c.c. of glacial acetic acid). One drop of this reagent added to 4–5 c.c. of the non-tannin filtrate will precipitate 1 part of tannin in 150,000. The "modified shake method" is carried out with a lightly chromed hide powder which does not alter on keeping and can be easily prepared. The method shows no anomalies and non-tannin filtrates are obtained which are always free from tannin, as shown by the gelatin-acetic acid reagent.—D. W.

Tannins. II. Hamameli-tannin. H. K. Freudenberg and D. Peters. Ber., 1920, 53, 953–961.

THE previous conclusion (J., 1919, 296A) that hamameli-tannin is an ester-like compound of gallic acid (2 mols.) and a hexose is confirmed. The latter consists of an aldo-hexose to the extent of 93% at any rate, but it has not been definitely identified. Various improvements in experimental technique are described, including the purification of hamameli-tannin, the preparation of tannase free from dextrose, the examination of the course of the reaction by measurement of the gradually increasing acidity of the solution, and the replacement of lead carbonate and basic lead acetate by prepared clay for the removal of gallic acid and tannin. (Cf. J.C.S., Aug.)—H. W.

XVI.—SOILS; FERTILISERS.

Soils; Acidity and acidimetry of —. Investigation of acid soils by means of the hydrogen electrode. H. G. Knight. J. Ind. Eng. Chem., 1920, 12, 457–451.

DETERMINATIONS were made with a new type of hydrogen electrode cell. When an acid soil is added to a neutral salt solution the hydrogen ion concentration reaches a maximum almost at once, but secondary reactions later cause a decrease in the concentration. If a free base is present in the salt solution, it is neutralised rapidly as indicated by the change in hydrogen ion concentration, but the hydrogen ion concentration of the solution continues to rise for an unknown period. There is no sharp break in the progress of base absorption by an acid soil such as would warrant differentiation of active and latent acidity, or immediate and eventual lime requirement. The changes in log C approach nearly straight line functions with progressive addition of base in the presence of a neutral salt solution; different indicators will give differences in lime requirement for soils depending on the slope of the log C curve, and the greatest differences occur with soils containing much organic matter. Insoluble products are formed when a base is added to an acid soil, calcium producing less soluble products than does potassium, but calcium and potassium hydroxides have equivalent

power in neutralising acid soils. The absorption of bases by acid soils is due largely to relatively insoluble acids.—W. P. S.

Soils; Lime requirement of — according to the Veitch method, compared with the hydrogen-ion concentration of the soil extract. A. W. Blair and A. L. Prince. Soil Sci., 1920, 9, 253–259.

WITH the samples of the particular soil examined (a loam soil which had received varying applications of lime) there appeared to be a fairly close correlation between the hydrogen ion concentration of the soil extract and the lime requirement of the soil as determined by the Veitch method. Samples which gave extracts with a hydrogen-ion concentration of about pH 6.7 or over were alkaline by the Veitch method. With soils containing a high percentage of organic matter certain inconsistencies appeared, however, due possibly to the presence of buffer substances.—W. G.

Soils; Hydrogen-ion concentration measurements of — in connection with their "lime-requirements." J. S. Joffe. Soil Sci., 1920, 9, 261–266.

THE results obtained are in fairly close agreement with those of Blair and Prince (preceding abstract).—W. G.

Soil; Relative absorption by — of sodium carbonate and sodium chloride. T. H. Kearney. Soil Sci., 1920, 9, 267–273.

WHEN equal volumes of solutions of equal concentration of sodium carbonate and of sodium chloride are added to the same weight of sand and allowed to remain in contact for 24 hrs., electrical resistance measurements indicate that the sodium carbonate is absorbed to a far greater extent by the sand than is the sodium chloride. Over the concentration range 0.1 to 1.0%, on the average, approximately 63% of the sodium carbonate, but only 23% of the sodium chloride was absorbed. This factor, as well as the partial formation of the less injurious bicarbonate, needs to be taken into account in investigating the comparative toxic effect of alkali salts on plants grown in soil cultures.—W. G.

Fertiliser material; Process and product of making —. P. McG. Shuey, Assr. to Savannah Chemical Co. and F. J. Gibson. U.S.P. 1,341,598, 25.5.20. Appl., 2.11.18.

MOLTEN nitre-cake is mixed with a phosphate-bearing material and an organic nitrogenous material.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Effect of varying the amount of "inoculum" and concentration on the deterioration of — by moulds. N. Kopeloff. J. Ind. Eng. Chem., 1920, 12, 455–457. (Cf. J., 1920, 380A.)

DETERIORATION increases with an increase in the number of mould spores inoculated into the sugar and with a decrease in concentration of the films surrounding the sugar crystals. At moisture ratios of less than 0.18 there is little, if any, de-

terioration with a mould infection of less than 5000 spores per grm.; at moisture ratios above 0.18 deterioration occurs with upwards of 100 spores per grm. Under similar conditions *Aspergillus Sydowi*, Bainier has a greater effect than *Penicillium expansum* or *A. niger*.—W. P. S.

Dextrose; Action of hydrocyanic acid on —. J. Bongault and J. Perrier. *Comptes rend.*, 1920, 179, 1395—1397.

WHEN an excess of potassium cyanide acts on dextrose the action is slow, the whole of the dextrose being combined only after at least two days at 20° C., and the time required increases with the dilution of the solution. If an excess of dextrose acts on potassium cyanide the whole of the cyanide is destroyed in 10 hrs. at 20° C., and the mixture is no longer toxic.—W. G.

Wood charcoal. Pickles. See IIb.

PATENT.

Fruit jellies etc. G.P. 303,995. See XIXA.

XVIII.—FERMENTATION INDUSTRIES.

Enzymic extract, polyzyme; Properties of a specially prepared — comparing its starch liquefying power with malt diastase. J. Takamine, jun., and K. Oshima. *J. Amer. Chem. Soc.*, 1920, 42, 4261—1265.

POLYZIME is an aqueous extract of diastatic enzymes, sp. gr. 1.03—1.06, containing many other enzymes, made from a specially prepared culture of *Aspergillus oryza* on media, consisting mainly of wheat bran. Its amylolytic power by Wohlgemuth's method is D 40°/30 min., 3.000; D 40°/24 hrs., 115.000; whilst Lintner's saccharogenic value at 21° is 43, and at 50°, 150°. Its diastatic power remains unchanged at the ordinary temperature for 6 months, but is diminished after 3 hrs. above 40° C.—J. K.

Acidity of worts, beers, and other physiological liquids; New method for determining —. III. Investigation of carbonates and phosphate-carbonate mixtures in presence of capillary active indicators of acid and alkaline nature. W. Windisch and W. Dietrich. *Woch. Brau.*, 1920, 37, 35—38, 43—46, 54—56, 70—71. *J. Inst. Brew.*, 1920, 26, 388—389. (*Cf. J.*, 1920, 128 A, 461 A.)

THE surface-tension methods previously described were applied to the study of the equilibria produced in solutions containing potassium, magnesium, or calcium carbonate (or bicarbonate), and monopotassium phosphate (*cf. J.*, 1920, 293 A). Eucupine dihydrochloride and undecylic acid were employed as "indicators."—J. H. L.

Filter pulp; Purification of — [in breweries]. R. Heuss. *Z. ges. Brauw.*, 1920, 43, 145—147, 154—156, 161—163. (*Cf. Foster, J.*, 1916, 1170.)

AN investigation of the purification of pulp from beer filters, including an account of a biological control of the usual method of purification as practised in ten different breweries. Provided the cakes have been completely disintegrated in the preliminary washing with cold, or preferably lukewarm water, sterilisation can usually be attained by heating for ½ hr. at about 80° C. If the apparatus contains less than 40—50 pts. of water to 1 pt. of dry pulp, longer heating or a higher temperature is desirable. Old pulp appears to be more difficult than new to sterilise, possibly owing to the presence of knots. After sterilisation the pulp always becomes more or less re-infected before it is replaced in the filter. The utmost cleanliness is necessary, and the whole series of operations—

washing, sterilising, pressing and replacement in the filter, should be completed with the least possible delay.—J. H. L.

Pyruvic acid, Fermentability of — under the conditions of the fraction method. [*Fermentation of pyruvate-sulphite by yeast.*] C. Neuberg and E. Reinthur. *Ber.*, 1920, 53, 1039—1052.

THE behaviour of the pyruvic acid-sulphite complex has been further studied, particularly with respect to its action under the influence of widely-varying classes of yeast and yeast preparations. The complex is at least as readily fermented, as is pyruvic acid itself (*cf. Zerner, J.*, 1920, 276 A). All types of yeast and yeast preparations decompose pyruvic acid in the presence of an equivalent or greater amount of sulphite and under suitable conditions of permeability (which appear to be comparable with the osmotic requirements of sugar fermentation); the pyruvic acid-sulphite complex, in spite of its stability, is more readily fermented than the unstable, sugar-sulphite compound. (*Cf. J.C.S.*, Aug.)—H. W.

Wines; Process of treating [clarifying] white —. L. Monnier. *Ann. Chim. Analyt.*, 1920, 2, 147—148.

CERTAIN white wines examined by the author contained a bright blue sediment consisting of ferric ferrocyanide; potassium ferrocyanide and gelatin had evidently been used for clarifying the wine. —W. P. S.

Wine vinegar; Determination of total solids in —. Aschoff and H. Haase. *Z. öffentl. Chem.*, 1920, 26, 4—6.

INDIRECT determination of the total solids in wine vinegar by the method of Lehmann and Gerum (*Z. Unters. Nahr. Genuss.*, 1912, 23, 267) gives more accurate results than a direct determination. The sp. gr. (*d*) of the vinegar is determined, the acidity titrated with N/1 sodium hydroxide solution, and the number of c.c. multiplied by 0.00018 ($=d'$). The difference between *d* and *d'* gives the sp. gr. of the extract solution, and from this the total solids are obtained by means of Windisch's table.

—C. A. M.

Alcohol; [Temperature] corrections for densities of —. H. D. Richmond. *Analyst*, 1920, 45, 222.

A TABLE gives the figures necessary to correct the sp. gr. to 15.5°/15.5° C., when the determination has been made between 10° and 15° C., or between 16° and 25° C., and covers a range of sp. gr. from 0.79 to 0.99.—W. P. S.

PATENT.

Grain; Process for steeping and malting —. O. Rummel. G.P. 318,701, 5.12.17.

GRAIN is treated with cellulose waste lyes or fermented cellulose lyes, which may be added to the steeping water. This shortens the steeping process, promotes oxidation, and prevents mould growth.

—C. A. M.

XIXA.—FOODS.

Wheat; Effect of premature freezing on composition of —. M. J. Blish. *J. Agric. Res.*, 1920, 19, 181—188.

PREMATURE freezing, i.e., freezing of the immature growing plant, affects the composition of wheat and the flour milled therefrom, the percentage of non-protein nitrogen, reducing sugars, and acid-reacting substances being higher in each case than in the corresponding sound products. The non-protein nitrogen of frozen wheat contains a considerably higher percentage of α-amino-nitrogen than that of sound wheat.—W. G.

Pearl barley. Its manufacture and composition. J. A. LeClerc and C. D. Garby. J. Ind. Eng. Chem., 1920, 12, 451—455.

THE pearling process consists in subjecting the barley to a scouring action between a revolving mill-stone and a surrounding sieve, the latter moving slowly in the opposite direction to the stone; from 5 to 6 pearling operations are necessary, and in each a certain amount of endosperm is removed, in addition to the husk and bran. The first two pearlings yield a product known as "pot barley" and cause a loss of 22% of the whole material, 25% of the protein, 41% of the fat, and 50% of the mineral constituents. In continuing the operations to produce pearl barley (6 pearlings) 65% of the barley material is removed, together with 74% of the protein, 80—85% of the fat, P_2O_5 , K_2O , CaO , and MgO , and 97% of the crude fibre and SiO_2 .—W. P. S.

Rangoon beans [; Hydrocyanic acid in —]. W. Koenig. Chem.-Zeit., 1920, 44, 405—408, 414—415, 433—434.

HYDROCYANIC acid (14—65 mg. per 100 g.) was found in 59 samples of Rangoon beans (*Phaseolus lunatus*). The enzyme in the beans is not destroyed by boiling, and the whole of the hydrocyanic acid is liberated from the glucoside by exposing the cooked beans for 24 hrs. to the action of water. The glucoside is not decomposed by pepsin with dilute hydrochloric acid. In the case of beans containing not more than 30 mg. HCN per 100 g., the hydrocyanic acid may be removed by twice soaking the beans for 24 hrs. with 5 times the amount of cold water, and then boiling them twice for 1 hr. with the same excess of water, which is renewed as it evaporates. Beans thus treated lose about 14% in weight, but are then non-toxic. The husks of a sample contained 6:1 and the kernels about 40 mg. HCN per 100 g.—C. A. M.

PATENTS.

Grain; Process and apparatus for converting — into paste or dough. J. C. A. Pointe. E.P. 117,271, 5.7.18. Conv., 5.7.17. Addn. to 8381 of 1913 (J., 1914, 330).

THE grain is washed and macerated in water and then subjected to pressure between rubber-covered rollers and superposed perforated plates in order to separate the pulp and husks; salt, yeast, etc., may be added during the pulping process. The washing apparatus consists of a cylinder fitted with a vertical rotating shaft provided with helical blades and the macerator has a constant temperature water-jacket.—W. P. S.

Vegetables and the like; Method and apparatus for drying —. S. Vlessing. E.P. 143,074, 20.6.19.

VEGETABLES are subjected to the action of superheated steam (at 180°—200° C.) for 5—10 mins., and then dried on cruciform screens in an upward current of hot air. The screens are arranged in horizontal layers, and by periodically rotating them the vegetables are transferred from one layer to the next lower one, and so on.—W. P. S.

Meat and fish and like food preparations; Preservation and treatment of —. E. G. Peyton and R. Ferguson. E.P. 143,669, 24.3.19.

THE food is immersed for a time in an electrolytic bath, which may contain common salt in solution, and then desiccated for preservation. Prior to use the product may receive a further electrolytic treatment.—J. H. L.

Milk; Reconstructed — and process of making the same. A. W. Bosworth, Assr. to The Boston Floating Hospital. U.S.P. 1,311,010, 25.5.20. Appl., 1.7.18.

NON-HUMAN milk is treated by first separating the

fat, together with fat-soluble vitamins, and the casein, then removing from the serum practically all the calcium and phosphorus, without any of the dissolved vitamins, and finally re-combining the resulting serum with a portion of the fat and with protein and calcium and phosphorus in substantially the same proportions as are present in human milk.—J. H. L.

Humanised milk; Preparation of —. H. Timpe. G.P. 319,022, 2.1.19.

FRESH cow's milk is enriched with fat and treated with a mixture of sodium and potassium pyrophosphates (3 g. per l.). The precipitated less digestible portion of the casein and most of the calcium salts are separated by heating and centrifuging, and the milk intimately mixed with a solution containing 9% of lactose.—C. A. M.

Fruit juices and jellies; Preparation of — from fruits and other vegetable products with the simultaneous manufacture of preserves. O. and C. Biemann. G.P. 303,995, 25.11.16.

FRUITS etc. are treated with the runnings from sugar refineries etc. (e.g., a solution of molasses) in a connected series of diffusion vessels.—C. A. M.

Lupin seeds; Process of preparing a flour free from bitter principles from —. J. D. Riedel. G.P. 319,591, 30.11.17.

LUPIN seeds are treated with a solvent for fats in the presence of alkali and then with strong alcohol, to obtain a flour suitable for human food.—C. A. M.

Preserving peas, beans, and other pulse. A. Bruff. E.P. 143,804, 20.12.19.

Drying vegetables and other materials; Processes and apparatus for —. A. A. Goubert. E.P. 144,080, 27.5.19.

SEE U.S.P. 1,305,599 and 1,305,600 of 1919; J., 1919, 597 A, 562 A.

XIXB.—WATER PURIFICATION; SANITATION.

Sewage; Purification of — by activated sludge. R. Cambier. Comptes rend., 1920, 170, 1417—1419.

A VERY slight trace of chloroform in the air bubbled through the sewage during purification by the activated sludge process is sufficient to inhibit the formation of nitrates. Similarly if air saturated with chloroform is bubbled through the sewage for 1 hr. and then pure air for 4 hrs. to remove the chloroform, on the introduction of the sludge and the subsequent bubbling of air, the ammonia disappears but no nitrates are formed. Further, attempts to isolate nitrifying organisms from activated sludges were not successful. These results are opposed to the view that nitrification takes place during the purification of sewage by the activated sludge process.—W. G.

PATENTS.

Water purification and softening; Manufacture of base-exchanging compound for —. J. Crossfield and Sons, Ltd., and H. J. Wheaton. E.P. 142,974, 21.3.19.

A COMPOUND of silica and soda for water purification and softening is prepared by neutralising dilute sodium silicate solution to the extent of about 50% of the sodium. The gelatinous mass obtained is dried at a low temperature, washed to remove soluble salts, and granulated. A suitable product contains 12.6% Na_2O and 87.4% SiO_2 .—W. J. W.

Sewage and other foul liquids; Apparatus for aerating —. R. Ames. E.P. 143,369, 28.4.19.

IN aerating tanks a movable device for raising

the sludge to the surface comprises a series of vertical pipes fixed in a carriage, the lower ends of the pipes being bell-mouthed, and the upper ends being provided with mushroom-shaped flanges. By means of an internal concentric pipe, and an air lift consisting of a conical box with apex below and slotted to allow air to escape upwards, or other suitable device, the sludge is raised to the surface through the bell-mouthed pipes, and then flows in a cascade over the mushroom flanges back into the tank, becoming aerated in the process.—W. J. W.

Sewage and other liquids; Purification of —. W. Jones. U.S.P. 1,341,561, 25.5.20. Appl., 8.8.19.

SEE E.P. 132,826 of 1918; J., 1919, 876A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Salvarsan and neosalvarsan; Examination of —. Utz. Süddeutsch. Apoth.-Zeit., 1920, 60, 187—188. Chem. Zentr., 1920, 91, 11, 772. (Cf. J., 1920, 246A.)

SALVARSAN preparations may be conveniently identified by Gaebel's reaction, according to which this compound gives the diazo reaction with α -naphthylamine, but not with β -naphthylamine. Salvarsan and neosalvarsan can be distinguished from one another by the following reactions: 5 c.c. of neosalvarsan solution (1:1000) with 0.1 c.c. of dilute hydrochloric acid gives a precipitate, soluble on boiling and not re-precipitated on cooling. Salvarsan gives no such precipitate. With an equal volume of acetic acid neosalvarsan solutions give a cloudiness changing to an orange-coloured precipitate on heating, whilst salvarsan gives a negative result. With ferric chloride both preparations give a green to red coloration, and with excess the salvarsan solution becomes dark red, and neosalvarsan violet. Mercuric chloride gives with salvarsan a heavy white precipitate, and with neosalvarsan an orange precipitate, both of which become somewhat grey or dirty on heating and rapidly sink to the bottom. Ammonium molybdate yields with salvarsan an olive-green precipitate and with neosalvarsan an olive coloration becoming dark green, but no precipitate. Platinic chloride gives only with neosalvarsan a flocculent precipitate which gradually settles. Picric acid produces with salvarsan solutions an intense yellow precipitate which is not dissolved on heating, whilst with neosalvarsan only a slight opalescence is produced after long standing. On the addition of a concentrated solution of sodium bisulphite the yellow salvarsan solution immediately becomes greyish-green, followed by a dirty grey cloudiness; on warming, the liquid becomes first green and then yellow, and finally a lemon-yellow precipitate is formed. Neosalvarsan gives no reaction with this reagent.—G. F. M.

Sympathomimetic amines. I. Amino-derivatives of naphthalene. A. Madinaveitia. Anal. Fis. Quim., 1920, 18, 66—78.

PHYSIOLOGICAL tests with amines of similar constitution to adrenaline but containing a naphthalene instead of a benzene nucleus, showed that a naphthalene compound is 40 times more active than a benzene one, and that introduction of a hydroxyl in the nucleus increases the physiological action of the compound.—W. R. S.

Saccharin analysis. O. Beyer. Chem.-Zeit., 1920, 44, 437—438.

The formula $x = 2.01329 \times c - 100/0.00845$ may be used to calculate the percentage (x) of *o*-benzoic-sulphimide in commercial saccharin when 1 g. of

the sample is titrated with $N/10$ potassium hydroxide solution using phenolphthalein as indicator; c is the number of c.c. of the alkali solution used.—W. P. S.

Salicylic acid; Melting point of —. W. J. Bush and Co. Perf. Essent. Oil Rec., 1920, 11, 207.

PURE salicylic acid has m.p. approximately 159° C., and products of m.p. 158° — 159° C. are regularly obtained in current British manufacture.

—G. F. M.

Chlorobenzenes; Catalysing action of aluminium in the preparation of —. J. Meunier. Comptes rend., 1920, 170, 1451—1452.

FOR the preparation of chlorobenzene aluminium is an excellent catalyst. To obtain a steady absorption of chlorine 1 pt. of aluminium per 1000 pts. of benzene by weight is used. If the action is stopped when the sp. gr. of the liquid reaches 1.008 a yield of 87% of monochlorobenzene can be obtained.

—W. G.

Chloroform and other volatile substances; Determination of —. A. Schlicht and W. Austen. Z. öffentl. Chem., 1920, 26, 55—57.

TO determine chloroform in a mixture of the same with alcohol, 5 c.c. of the sample is diluted with water to 200 c.c., shaken with 60 c.c. of ether, and, after separation, the sp. gr. of the ether is determined. Each increase of 0.0001 in the sp. gr. corresponds with 0.1786 g. of chloroform in the alcohol-chloroform mixture. The sp. gr. of the latter gives an approximate measure of the alcoholic strength, after the chloroform has been determined and an allowance made for its sp. gr.

—W. P. S.

Camphor; Examination of Chinese crude —. E. R. Dovey. Analyst, 1920, 45, 220—221.

MOISTURE is determined by the carbide method, allowing 3 hrs. for the evolution of the gas. To determine water and oil, 100 g. of the sample is pressed between layers of lint in a steel cylinder, 2 in. in diam. and 6 in. deep, having a perforated bottom plate and a piston worked by a strong screw thread; after 15 mins., the cake is removed and weighed. The moisture content of the pressed cake is determined, and from this are found the amounts of expressed water and oil. The total quantity of oil is calculated on the assumption that the residual water and oil in the pressed cake are in the same proportion as they are in the expressed liquid.

—W. P. S.

Oil of chenopodium from various sources; Composition of —. E. K. Nelson. J. Amer. Chem. Soc., 1920, 42, 1204—1208.

THE need for distilling chenopodium oil in a rapid current of steam, keeping the condenser water warm, and rejecting the water separating from the oil in the receiver, in order to avoid as far as possible decomposition of ascaridol (cf. J., 1908, 710; 1911, 1279) is confirmed. By distillation with low-pressure steam, oil of low ascaridol content was obtained, there being a distillation residue of 7—25%, soluble in water and probably consisting of glycols (cf. J., 1913, 379), as against 2.3%, with more rapid distillation and the precautions stated above. The proportion of ascaridol, determined by distillation under 3—6 mm. pressure, in oil from Carroll County, Maryland, U.S.A., amounted to 60—77%, from Java 70%, from Florida (dry plants) 41%, from Eastern U.S.A. (wild plants) 20%, whilst samples a year old were found to have deteriorated little, if at all. *p*-Cymene, *l*-limonene, and probably α -terpinene are also present in the oil.

—J. K.

Rubiera multifida; [Essential] oil of —. E. K. Nelson. J. Amer. Chem. Soc., 1920, 42, 1286.

A SAMPLE of the light yellow oil from California, sp. gr. 0.8512 at 25°/25° C., $[\alpha]_D^{25} = +35.75$, contained 85% of terpenes, largely β -phellandrene, and also anethole.—J. K.

Tea leaves; Unsaturated alcohol of the essential oil of freshly fermented —. P. van Romburgh. Proc. K. Akad. Wetensch. Amsterdam, 1920, 22, 758–761.

The alcohol appears to be a hexene-3-ol-6. (Cf. J.C.S., Aug.)—J. C. D.

Alkali in organic salts; Estimation of — as sulphate. C. F. van Duin. Chem. Weekblad, 1920, 17, 283–284.

THE alkali salt is evaporated with concentrated sulphuric acid until fuming ceases. The resulting mixture of sulphate and pyrosulphate is dissolved in a little ammonium carbonate solution, the solution is evaporated to dryness, and the residue gently ignited. In this way losses by spurring are avoided, and any carbonaceous matter is easily burned off.—W. S. M.

Bromine chloride and ethylene. Delépine and Ville. See VII.

Conductimetric titrations. Kolthoff. See XXIII.

PATENTS.

Acetic acid; Production of — from paraldehyde as the primary material. Soc. des Acieries et Forges de Firminy. E.P. 121,195, 18.2.19. Conv., 13.3.18.

PARALDEHYDE is directly converted into acetic acid by electrolytic oxidation in a cell provided with a porous cathode, e.g., gas carbon, and a refractory anode, such as magnetite or platinum, using a high current density and 10% sulphuric acid as the electrolyte. The paraldehyde is poured on to the surface of the acid and dissolves until a concentration of 10–15% is reached; the excess floats on the surface and dissolves as the oxidation proceeds. Oxidation is facilitated by the addition of a small quantity of a salt of a metal capable of several degrees of oxidation, such as manganese, cerium, molybdenum, or vanadium. The concentration of the acetic acid may be carried to about 40%, and it is then separated from the sulphuric acid by distillation.—G. F. M.

Ethyl acetate; Manufacture of — from paraldehyde as primary material. Soc. des Acieries et Forges de Firminy. E.P. 131,600, 18.2.19. Conv., 13.3.18.

By adding to the mixture of acetic acid and dilute sulphuric acid produced by the electrolytic oxidation of paraldehyde (preceding abstract), a quantity of ethyl alcohol equivalent to the acetic acid which it contains, and distilling the whole in a rectifying apparatus, esterification is effected and pure ethyl acetate distils. The liquid remaining, containing sulphuric acid and a little non-esterified acid and alcohol, may be again employed as a basis for a fresh electrolysis.—G. F. M.

[Hydr]oxyaldehydes and their ethers; Manufacture of —. A. Weiss. E.P. 139,153, 6.1.20. Conv., 18.2.19.

AROMATIC hydroxyaldehydes or their ethers are obtained by the interaction of an aromatic nitroso-compound such as nitrosobenzene, *p*-nitrosodimethylaniline, etc., and a mixture of formaldehyde with a phenol or phenol ether. For example, an excellent yield of vanillin is obtained by heating for several hours on a water-bath a mixture of

equimolecular proportions of guaiacol and formaldehyde and half a mol. of *p*-nitrosodimethylaniline, methyl or ethyl alcohol being added as a diluent, and gaseous hydrogen chloride being bubbled through continuously. The reaction mixture is then treated with sodium hydroxide, the alcohol distilled off, the by-product, *p*-aminodimethylaniline, extracted with benzene, and the residue acidified and again extracted with benzene to remove the crude vanillin, which is purified by distillation in vacuum.—G. F. M.

$\beta\beta$ -Dichloroethyl sulphide; Production of —. W. J. Pope, C. S. Gibson, and H. F. Thuillier. E.P. 142,875, 3.4.18.

$\beta\beta$ -DICHLOROETHYL sulphide is obtained in upwards of 90% yield by passing dry ethylene into sulphur monochloride heated to and maintained at 50°–70° C. (cf. J., 1920, 383 A).—G. F. M.

Chloropierin; Production of —. K. J. P. Orton and W. J. Pope. E.P. 142,878, 9.5.18.

CHLOROPIERIN is obtained by the action of chlorine on picric acid or other suitable nitro-phenol, in presence of sufficient aqueous alkali, preferably sodium or potassium hydroxide or carbonate solution, to dissolve the nitro-derivative and neutralise the acid produced in the reaction: $C_6H_2(NO_2)_3OH + 11Cl_2 + 5H_2O = 3CCl_3(NO_2) + 13HCl + 3CO_2$.—G. F. M.

Arsenic compounds [mono- and di-arylarsonious halides]; Production of aromatic —. W. J. Pope. E.P. 142,880, 11.6.18.

MONO- and di-arylarsonious halides are obtained by bringing an arsenious halide in the liquid or vapour form into intimate contact with a triarylarsine heated to a high temperature under atmospheric pressure. According to the proportion of arsenious halide employed reactions expressed by the following equations, in the typical case of the phenylarsenious chlorides, occur:—

For these reactions a temperature approaching 350° C. is favourable. The products may be separated by physical or chemical means, or should the diaryl compound be required as the main product any mono-aryl compound present may be converted by gently boiling with triphenylarsine as expressed by the fifth equation, and, conversely, should the mono-aryl compound be required, any diaryl arsenious chloride present may be transformed according to the fourth equation.—G. F. M.

Arsinic acids; Process of preparing aromatic —. A. Mouneyrat. E.P. 112,917, 20.2.19.

AROMATIC arsinic acids are produced by the interaction of aromatic diazonium compounds with cold or warm aqueous or dilute alcoholic solutions of arsenious acid, in an acid, neutral, or alkaline medium in the presence of a copper salt and a reducing agent adapted to the acid or alkaline medium employed. In acid medium hypophosphorous acid or cuprous hydroxide are suitable, whilst in a neutral or alkaline medium sodium hydrosulphite, sodium formaldehydesulphoxylate, or even an excess of alkali arsenite, may be employed. The method of procedure is capable of numerous modifications in detail, of which examples are given.—G. F. M.

Benzoic acid; Production of —. W. P. Thompson. From Les Etabl. Poulenc Frères, J. B. Senderens, and J. Aboulenc. E.P. 143,392, 27.5.19.

BENZOIC acid is obtained from toluene by oxidation with a mixture of sulphuric acid and manganese dioxide, the reaction mixture being maintained at

60°–70° C., whereby only small quantities of benzaldehyde escape further oxidation, and only traces of carbon dioxide are formed by the further oxidation of benzoic acid. The operation is conducted in a closed jacketed vessel fitted with arrangements for steam heating and water cooling, with an agitator, and with a gas meter to record the evolution of gas. The sulphuric acid and manganese dioxide are introduced into the toluene in small quantities at a time in order to prevent a rise of temperature, and any notable evolution of carbon dioxide is at once checked by cooling the reaction mixture, which is, however, maintained at the highest temperature possible consistent with the above conditions. From 200 kg. of toluene on treatment with 400 kg. of manganese dioxide and 2000 kg. of sulphuric acid (52°–53° B., sp. gr. 1.56–1.58) there are obtained 100 kg. of benzoic acid, 8 kg. of benzaldehyde, and 100 kg. of recovered toluene.—G. F. M.

Thymol; Synthetic manufacture of —. M. Phillips. U.S.P. 1,332,680, 2.3.20. Appl., 8.9.19.

p-Cymene is nitrated, the nitro-compound reduced to the amino derivative (cymidine), the latter is sulphonated, the amino group eliminated, and the sulphonic acid subjected to alkali fusion.—L. L. L.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Coloured [photographie] sensitizers derived from quinolines, quinaldines, and lepidines containing dimethylamino and diethylamino groups. H. Barbier. Bull. Soc. Chim., 1920, 27, 427–439.

THE author has prepared the methiodides and ethiodides of *p*-dimethylaminoquinoline, of 6-diethylaminoquinoline, of 6-dimethylaminoquinoline, and of 6-dimethylaminolepidine, and finds that when these alkyl iodides containing a dialkylamino group are condensed amongst themselves or with alkyl iodides of other bases or with *p*-dimethylaminobenzaldehyde, they give a series of new colouring matters belonging to the cyanines. All of these cyanines, which contain the active auxochrome group, $N(CH_3)_2$ or $N(C_2H_5)_2$, can be used as photographic sensitizers. (*Cf.* J.C.S., Ang.)—W. G.

Photographic plate; Action of phosphorus, during oxidation, on the — and its ionising power. W. P. Jorissen. Rec. Trav. Chim., 1920, 39, 429–431.

A REPLY to Centnerszwer and Petrikalu (*Z. physik. Chem.*, 1912, 80, 235), in which it is shown that the effects obtained on a photographic plate by phosphorus in process of oxidation depend upon the velocity of the current of air removing the mist produced by the oxidation and on the temperature.—W. G.

XXII.—EXPLOSIVES; MATCHES.

Cellulose and its esters. I. Fractional precipitation of nitrocelluloses. J. Duclaux and E. Wollman. Bull. Soc. Chim., 1920, 27, 414–420.

NITROCELLULOSE can be divided into a number of fractions, which have widely differing viscosities in acetone solution, by fractional precipitation from its acetone solution by means of aqueous acetone or water. By repeating this process with the extreme fractions, samples were obtained, the viscosities of which in 2% acetone solution were as 46:1, and at one end a nitrocellulose was obtained, which in 1% acetone solution was as viscous as pure glycerol. These fractions obey the law of mixtures in so far as their viscosities are concerned, and the nitrogen content of the different fractions from one and the same operation is practically constant. A better

method of separation of the fractions is probably by filtration through a series of ultra-filters. The different nitrocelluloses can best be characterised and differentiated by osmotic pressure measurements.—W. G.

Powders and explosives; Analysis of —. *Differentiation of trinitroglycerin and dinitroglycol.* Marquoyrol and E. Goutal. Bull. Soc. Chim., 1920, 27, 443–448.

DINITROGLYCOL may be differentiated from trinitroglycerin either by the steady spontaneous loss in weight of the former when exposed in a desiccator over sulphuric acid at 12° C. at the ordinary pressure, the latter not losing in weight, or by their different effects in depressing the freezing-point of benzene, the former lowering the freezing-point in 10% solution by 3.06° C. and the latter by 2.13° C. Either of these methods is applicable for the estimation of the percentages of these two substances present in a mixture, and the results are not appreciably vitiated by the presence of impurities such as vaseline, diphenylamine, dimethyldiphenylurea, diethyldiphenylurea, or dinitrotoluene. For a correct interpretation of the results it is advisable to determine in the ether extract the substances other than dinitroglycol or trinitroglycerin.—W. G.

Nitration of m-nitrotoluene. Marquoyrol, Kohler, and Jovinet. Bull. Soc. Chim., 1920, 27, 420–424.

WHEN *m*-nitrotoluene is nitrated with a mixture of 16 pts. of sulphuric acid (98%) and 2.25 pts. of nitric acid (88%) for 8 hrs. at 100° C., a mixture of 2.3.4-, 3.4.6- and 2.3.6- or 2.3.5-trinitrotoluenes is obtained.—W. G.

Trinitration of o-xylene. Marquoyrol and P. Loriette. Bull. Soc. Chim., 1920, 27, 424–426.

By passage through its mono- and dinitro-derivatives without purification of these, but using fresh nitration mixtures at each stage, *o*-xylene gave the two trinitro-*o*-xylenes previously described by Crossley and Renouf (*Chem. Soc. Trans.*, 1909, 202).—W. G.

Mercury fulminate in mixtures for detonators; Direct estimation of —. Marquoyrol. Bull. Soc. Chim., 1920, 27, 448.

A QUANTITY of 1–1.5 g. of the mixture is extracted on a filter with 25–30 c.c. of a 5% solution of potassium cyanide. The filtrate is collected in the dish of a Riche's apparatus, and the mercury is deposited on the dish by electrolysis and weighed as such after washing with water and alcohol.—W. G.

Chemicals [nitrates and aluminium] used in pyrotechnics; Short commercial analytical methods for determination of purity of —. H. B. Faber and W. B. Stoddard. J. Ind. Eng. Chem., 1920, 12, 576–578.

FOR the determination of small amounts of sodium in potassium nitrate, 1 g. is dissolved in 5 c.c. of water, 1 c.c. of 2N nitric acid added, and then 10 c.c. of an acid solution of potassium nitrate, bismuth nitrate, and caesium nitrate (Ball, J., 1910, 46, 902), several precipitations being made simultaneously in Erlenmeyer flasks. After connecting the flasks, coal gas is passed through them, and the series is then closed at one end by a glass plug and at the other by a Bunsen valve. The flasks are allowed to stand in a cool place for 48 hrs., and the precipitate is collected in a Gooch crucible and washed with acetone, filtration being conducted rapidly to reduce exposure to the air. The crucible is dried in air bath at 100° C. for 30 mins., and the weight of sodium calculated from weight of precipitate $\times 0.03676$. Alternatively the caesium sodium

bismuth nitrate may be determined volumetrically by titration with potassium permanganate. The determination of nitrate in commercial salts is effected by decomposition with tungstic anhydride. 1 g. of nitrate is carefully heated with 5 g. of tungstic anhydride in a platinum crucible over a Bunsen burner, the percentage of pure nitrate being calculated from the loss, due to liberation of oxygen and oxides of nitrogen. For the estimation of aluminium in flake or powder, its reducing power on litharge is utilised. 3 g. of aluminium is mixed with 100 g. of litharge and 30 g. of borax glass, 25 g. of the latter being added for covering. The mixture is fused in a muffle, and after 20 mins. the molten lead is separated, freed from slag, and weighed, its weight $\times 0.0872$ representing the aluminium.—W. J. W.

Nitration of naphthalene. Pascal. See III.

PATENTS.

Explosives for detonators; Manufacture of —. W. Rintoul, J. Weir, A. G. Lowndes, and Nobel's Explosives Co., Ltd. E.P. 142,898, 10.1.19.

THE sensitiveness to shock of explosives such as lead azide is reduced by precipitating the azide from solution as an amorphous, or abnormally crystalline, or micro-crystalline powder, in presence of a colloid, such as gelatin. The fine powder obtained may be "corned" by addition of gum or starch. —W. J. W.

Priming mixture. A. S. Cushman. U.S.P. 1,325,928, 23.12.19. Appl., 20.8.18.

A MIXTURE of a "nitrated fuel body," e.g., tetranitromethylaniline (tetryl), and a variable proportion of a non-combustible basic oxide, such as litharge, together with other known ingredients (antimony pentasulphide, lead thiocyanate, potassium chlorate).

Loose compounds [explosives]; Manufacture of —. J. E. Bloom. U.S.P. 1,333,701, 16.3.20. Appl., 3.12.17.

IN the production of loose compounds, including explosives, nitro-substitution products, composite nitro explosives, nitrocellulose, etc., the components are dissolved in suitable liquid mobile media and the solutions blended and mixed under insulated conditions in an alternating current field or fields of regulated frequency and strength, and under suitable conditions of temperature, speed, and time.—L. L. L.

Explosive propellent powder. F. I. du Pont. U.S.P. 1,341,207, 25.5.20. Appl., 28.4.19.

A PROPELLENT powder consists of finely-divided ammonium nitrate embedded in a small proportion of a substance which forms a matrix for it, a non-porous mass being obtained on hardening.

—W. J. W.

Detonating fuse. W. C. Cope, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,341,705, 1.6.20. Appl., 4.6.19.

THE detonating mixture is composed of trinitrophenylmethylnitramine and trinitrotoluene.

—W. J. W.

Pyroxylin; Solvent for use with — and compositions containing the same. E. M. Flaherty, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,341,710, 1.6.20. Appl., 11.9.18.

A MIXTURE containing amyl acetate, *n*-butyl alcohol, and benzene is used as a solvent for nitrocellulose.

—W. J. W.

XXIII.—ANALYSIS.

Platinum wire in flame and bead tests; Substitutes for —. C. C. Kiplinger. J. Ind. Eng. Chem. 1920, 12, 500.

THE "lead" from a blacklead pencil is heated to redness, dipped in borax, and again held in the flame so that a hanging drop of borax glass is formed at the end. The reducing action of the carbon does not interfere with subsequent bead tests. The filter paper method of Ehringhaus (J., 1920, 315 a) is rendered more useful by inserting the rolled strip into a glass tube containing the solution etc. under examination. The mouth of the tube is constructed so that the paper fits it tightly, and about 3 cm. of the strip is allowed to project so as to form a wick.—C. A. M.

Bulb; Connection — for distillations. C. M. Clark. J. Ind. Eng. Chem., 1920, 12, 366.

THE upper tube of an anti-spray bulb passes a short distance into the bulb, and a baffle-plate, in the form of an inverted watch-glass, is attached to the lower end of the tube; the edge of the baffle-plate reaches to within 5 mm. of the inner wall of the bulb, forming a narrow channel for the passage of the vapours. A hole in the portion of the upper tube inside the bulb allows the vapours to escape through the tube to the condenser.—W. P. S.

Melting points; Apparatus for the determination of —. L. M. Dennis. J. Ind. Eng. Chem., 1920, 12, 366—368.

TO obtain a better circulation and more uniform temperature of the sulphuric acid in the type of apparatus proposed by Thiele (J., 1907, 435), the lower portion of the tube is inclined slightly downwards and is then constricted and bent upwards to the point where it enters the main or vertical tube. —W. P. S.

Densimeter; New industrial — for gases. E. Hauser. Anal. Fis. Quim., 1920, 18, 79—82.

A DENSIMETER for continuous readings, having no metallic parts, consists of a glass bell jar through which the gas is passed. A cylinder within the enclosed space contains water (for moist gases) or paraffin (for dry gases) in which is immersed an areometer provided with a closed glass bulb at the top of its graduated stem. The areometer sinks if the gas be lighter, and rises if heavier, than air. —W. R. S.

Conductometric titrations; Use of — in neutralisation analysis. I. Neutralisation of acids and bases. I. M. Kolthoff. Z. anorg. Chem., 1920, 111, 1—27.

TITRATIONS are carried out by running comparatively strong alkali solution into the dilute acid solution and determining the conductivity at intervals. The neutralisation curve is obtained by plotting conductivities as ordinates against volume of alkali added as abscissae. When a strong acid is titrated with a strong base, the neutralisation curve is a straight line descending sharply to the neutral point and then rising sharply as a second straight line as the solution becomes increasingly alkaline. When a comparatively weak acid, such as salicylic acid, is titrated with a strong base, the neutralisation curve passes through a minimum before the neutral point is reached, and this point is not sharp. It may be found, however, by determining the conductivity-concentration curve of the salt, which cuts the neutralisation curve at the neutral point. A very weak acid may be titrated with a strong base if the dissociation constant is not less than 10^{-10} when the concentration of the solution is 0.1N, or 10^{-9} for a 0.01N solution. The neutralisation curve then consists of a rising straight line which changes direction more or less

sharply at the neutral point. Boric acid and phenol were successfully titrated with sodium hydroxide. A weak acid can be titrated with a weak base if their dissociation constants are greater than 3×10^{-6} . Thus acetic acid can be titrated with ammonia, but boric acid cannot because, on account of the hydrolysis of the neutral salt, the neutralisation curve is rounded off on either side of the neutral point. (Cf. J.C.S., ii., 420.)—E. H. R.

Conductometric titrations; Use of —, in neutralisation analysis. II. Simultaneous titration of different acids or bases. I. M. Kolthoff. Z. anorg. Chem., 1920, 111, 28—51.

A STRONG and a weak acid in equal concentrations in 0.1N solution can be titrated together and good results obtained if the dissociation constant of the weaker acid is less than 4×10^{-4} . With weaker solutions or greater relative concentration of the weaker acid, the dissociation constant of the latter should be smaller. The neutralisation point of the strong acid is best found as the intersecting point of the salt conductivity curve and the neutralisation curve (cf. preceding abstract). The dissociation constant of the weaker acid may be lowered, and sharper results obtained, by addition of alcohol. Two weak acids can be titrated together in equal concentrations when the ratio of their dissociation constants is smaller than 0.001, provided the ionic mobilities of the anions are not too closely similar. Thus oxalic and tartaric acids or oxalic acid and phenol can be titrated together, but not acetic acid and phenol, because the change of direction of the curve at the point of neutralisation of the first acid is too slight. When a dibasic acid is titrated, the first neutralisation point can hardly be detected, but oxalic acid is exceptional, on account of the wide difference between its first and second dissociation constants. (Cf. J.C.S., ii., 421.)—E. H. R.

Potassium hydrogen phthalate as a standard in volumetric analysis. W. S. Hendrixson. J. Amer. Chem. Soc., 1920, 42, 724—727.

POTASSIUM hydrogen phthalate for use as a standard in volumetric work (J., 1915, 1118) is best prepared from phthalic anhydride and potassium carbonate, and is obtained absolutely pure by three crystallisations; it contains no water of crystallisation and is not hygroscopic. A saturated solution contains 10.23% of the salt at 25° C. and 36.12% at the boiling point.—J. F. S.

Titration curves; Colorimetric determination of —. L. J. Gillespie. J. Amer. Chem. Soc., 1920, 42, 742—748.

TITRATION curves are obtained colorimetrically without the use of a "buffer" mixture. A colour standard is used, consisting of a pair of test-tubes containing together 10 drops of indicator solution of suitable strength, the drop ratio in the two tubes being varied from 1:9 to 9:1. One of the tubes contains dilute alkali and the other dilute acid. Reference to a table gives the hydrogen exponent corresponding to the drop ratio, or the exponent can be calculated from the ratio $pH = k + \log(\text{drop ratio})$, where the drop ratio is the ratio of the number of drops of the indicator solution in the alkali tube to that in the acid tube, and k is a constant depending on the indicator. It has the following values: tetrabromophenolsulphonophthalein, 4.1; methyl red, 5.0; dibromo-*o*-cresolsulphonophthalein, 6.3; dibromothymolsulphonophthalein, 7.1; phenolsulphonophthalein, 7.7; *o*-cresolsulphonophthalein, 8.1; and thymolsulphonophthalein, 8.8.—J. F. S.

Potassium; Estimation of — as perchlorate. G. P. Baxter and M. Kobayashi. J. Amer. Chem. Soc., 1920, 42, 735—742.

THE method previously described (J., 1917, 354) is modified by using absolute alcohol containing 1%

perchloric acid for the initial extraction of sodium perchlorate from the precipitate before washing it with a saturated solution of potassium perchlorate. (Cf. J.C.S., ii., 388.)—J. F. S.

Manganese and zinc; Detection of — in the presence of phosphates and oxalates. E. Schmidt. Ber. deuts. Pharm. Ges., 1920, 30, 217—218.

ZINC and manganese are precipitated as sulphides by ammonium sulphide in the presence of phosphoric or oxalic acid, and not as phosphates or oxalates, as stated by Wester (cf. ante), and their separation from one another may then be effected by the difference in solubility of the respective hydroxides in ammonia and ammonium chloride solution. (Cf. J.C.S., ii., 289.)—C. A. M.

Radium; Practical methods for the determination of —. III. Alpha-ray method, gamma-ray method, miscellaneous. S. C. Lind. J. Ind. Eng. Chem., 1920, 12, 469—472. (Cf. J., 1915, 610; 1916, 113).

IMPROVEMENTS in the construction of the interchangeable electroscope (*loc. cit.*) are described, and consist of the substitution of amber or amberoid insulation instead of sealing-wax for both insulators, the use of metal stopcocks brazed into the chamber, and adjustable fittings for the microscope holder. Whilst the alpha-ray method is trustworthy for qualitative and very rough quantitative purposes, it is not sufficiently accurate for scientific control or when a mineral is sold on the result obtained by the method. The three chief sources of error are the variation in the amount of loss of radium emanation by gaseous diffusion from the ore, the variability of the radium-uranium ratio in the ore, and the position of the radioactive material in the individual grains. In the gamma-ray method, the radium preparation must be confined in a closed vessel to prevent escape of gas; the measurement may be made after the vessel has been closed for a month or more, the gamma-radiation having then reached a constant maximum which is directly proportional to the quantity of radium present.—W. P. S.

Molybdenum; Application of rotating zinc "reductor" to determination of —. W. Scott. J. Ind. Eng. Chem., 1920, 12, 578—580.

MOLYBDIC acid in dilute sulphuric acid solution may be reduced at 20°—30° C. by a rotating zinc cylinder, the containing beaker being kept covered during the reduction by a split cover-glass which serves to retain enough hydrogen to act as a protective covering for the zinc. After reduction the solution may be titrated in the same beaker with permanganate, or it may be transferred to another beaker containing ferric alum solution and syrupy phosphoric acid.—W. J. W.

Nitric nitrogen; Apparatus for the determination of — by Devarda's method. J. Erlich. Ann. Chim. Analyt., 1920, 2, 143—144.

THE apparatus consists of a reaction flask, a condenser, and a receiver; an anti-spray bulb is placed between the flask and the condenser, the bulb being partly filled with glass beads. A central tapped tube extends downwards through the bulb to the bottom of the flask, so that a current of air may be drawn through the apparatus to carry over the last traces of ammonia.—W. P. S.

Diphenylamine reaction [for nitrates]; Colour changes of the —. E. M. Harvey. J. Amer. Chem. Soc., 1920, 42, 1245—1247.

A MODIFIED diphenylamine reagent for use in microchemical tests for nitrates in plant tissues consists of 0.5 g. of diphenylamine, 7.5 c.c. of sulphuric acid (95—96%), and 2.5 c.c. of 10% aqueous potassium chloride solution; or, if it is particularly de-

sirable to avoid darkening of plant tissues, 5 c.c. of sulphuric acid, 3 c.c. of glacial acetic acid, and 2 c.c. of 12% aqueous potassium chloride solution may be used at some sacrifice of colour intensity. A diagram is given showing the variation of colour, shade, and intensity with strength of sulphuric acid. The proportion of diphenylamine is variable between fairly wide limits, but in excess it interferes with the reaction; variations of temperature between 20° and 50° C. have little effect; potassium chloride causes not only an intensification of the blue colour, but an extension in both directions of the concentrations of sulphuric acid which produce it, and is more suitable for this purpose than sodium chloride owing to the greater solubility of its acid sulphate. The stability of the blue colour once produced, even in concentrations of acid in which normally it would not be produced, renders the order of mixing of some importance. (*Cf.* J.C.S., Aug.) — J. K.

Benzidine sulphate; Solubility of — in water. C. S. Bisson and A. W. Christie. J. Ind. Eng. Chem., 1920, 12, 485—486.

The solubility of benzidine sulphate in water at various temperatures was as follows:—At 0° C., 0.049; at 25° C., 0.098; at 50° C., 0.141; and at 80° C., 0.290 (by evaporation), and 0.252 (by titration) g. per l. Hence in washing benzidine sulphate in the quantitative determination of sulphate the minimum amount of cold water should be used. (*Cf.* J.C.S., ii., 385.)—C. A. M.

Gas analysis; Combustion apparatus for use in —. E. R. Weaver and P. G. Ledig. J. Ind. Eng. Chem., 1920, 12, 368—370.

A combustion pipette having a capacity of about 150 c.c. has two short side tubes between which a platinum spiral is strung; the ends of the spiral extend down the side tubes and connect with platinum leads sealed through glass caps closing the ends of the tubes; the caps are cemented on to the tubes and are readily removed when necessary. A combustion capillary may be constructed on the same principle; the capped side tubes are fused on to opposite sides of the capillary, one below the other, and a platinum spiral is strung between them. This portion of the capillary is surrounded by a small water jacket.—W. P. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Acton and McKean. Separation of solids from liquids. 19,131. July 7.

American Drying Processes, Inc. Desiccation. 19,982. July 9. (U.S., 27.3.19.)

Balthasar. Jets for evaporating liquids. 20,008. July 9. (Belg., 11.6.18.)

Bennett. Separation of solids of different specific gravity etc. 19,830. July 9.

Bloomfield. Still. 18,108. July 2.

Bowrey, and Duckham and Co. Centrifugal separators. 18,739. July 5.

Chem. Fabr. vorm. Weiler-ter Meer. Centrifugal pumps for acids. 18,203 and 18,396. July 2. (Ger., 28.9.16 and 19.11.17.)

Clark. Pulverising, mixing, etc. apparatus. 19,455. July 8.

Continuous Reaction Co., Skelley, and Smith. Means for mixing granular etc. substances. 18,321. July 2.

Dobblestein. Production of briquettes. 20,011. July 9. (Ger., 21.3.14.)

Dorr Co. Selective recovery of organic materials from liquids. 19,267. July 7. (U.S., 1.7.19.)

Dow. Drying apparatus. 20,100. July 9.

Elektro-Osmose A.-G. Process for extracting materials. 18,521. July 3. (Ger., 3.7.19.)

Fairlie. Filling material for reaction spaces. 19,919. July 9. (U.S., 23.3.18.)

Freytag. Washing gases and vapours. 18,319. July 2. (Ger., 19.8.18.)

Granichstädten and Sittig. Hydration and production of catalysts. 19,511. July 8. (Austria, 7.7.17.)

Hutchins. Drying apparatus. 18,495. July 3.

Juer and Smeu. Apparatus for dissolving materials with acids etc. 20,025. July 9. (Austria, 20.12.15.)

Krupp A.-G. Acid-resisting pipes, boilers, etc. 18,030. July 2. (Ger., 17.6.18.)

Martini u. Humeke A.-G. Producing inert gases for fire-prevention. 19,579. July 8. (Ger., 23.9.16.)

Mazza. Separating elements of gaseous mixtures. 19,236. July 7. (Ital., 7.9.15.)

Müller. Devices for separating constituent parts of heterogeneous mixtures. 17,561. June 28. (Ger., 10.2.19.)

Norma Comp., and Schweickardt. Grinding-machines. 19,890-1. July 8. (Ger., 26.2 and 1.3.18.)

Norton Co. Grinding machines. 19,659—19,661. July 8. (U.S., 21.7.14 and 28.6.15.)

Petzel. Separation of gas mixtures. 20,214. July 9. (Ger., 9.1.14.)

Schmidt. Reaction towers. 19,290. July 7. (Ger., 11.4.19.)

Soc. l'Oxylythe. Washing and drying gases. 18,379. July 2. (Fr., 22.1.19.)

Soc. Anon. Entreprises Simon-Carves. Rotary furnaces. 20,273. July 9. (Fr., 4.6.18.)

Teichner. 18,394. See X.

United Filters Corp. Rotary suction filters. 17,538. June 28. (U.S., 24.5.17.)

Vivies. Apparatus for washing or extracting liquids. 19,745. July 8. (Fr., 26.3.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

13,032 (1919). Brinjes and Goodwin, and Harris. Mixing and/or agitating machines. (115,230.) July 7.

4032 (1920). Fabry. Continuous stills for dissociating chemical solutions by heat. (146,058.) July 14.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Akt.-Ges. f. Brennstoffvergasung. Treatment of coking coals for extraction of nitrogen. 20,164. July 9. (Ger., 17.11.16.)

Avray. Gasoline etc. producing apparatus. 19,631. July 8. (Ger., 11.12.13.)

Bale and Perkin. Apparatus for destructive distillation of carbonaceous material. 18,145. July 2.

Bates. Fuel. 18,914. July 6.

Berzlit Ges. Distillation of low-grade fuels. 20,317. July 9. (Ger., 26.10.18.)

Bronn., and Rombacher Hüttenwerke. Treatment of coke-oven gases. 18,709 and 19,015. July 5 and 6. (Ger., 24.10 and 21.11.14.)

Brown and Oswald. Apparatus for extracting oil from sandstone, shale, etc. 19,202. July 7.

Brownlee. Apparatus for treating hydrocarbon oils. 17,578. June 28. (U.S., 11.7.17.)

Burnell. Conversion of liquid hydrocarbons into motor spirit. 19,073. July 7.

Cannon. Carbonising. 19,262. July 7.

Collin A.-G. Sealing retorts and oven chambers. 18,166. July 2. (Ger., 28.4.19.)

Collin A.-G. Recovering by-products from fuel gases. 19,592. July 8. (Ger., 3.3.19.)

Coppée and Co. Regenerating furnaces. 19,741. July 8. (Belg., 20.1.19.)

Coppée and Co. Coking ovens. 19,742. July 8. (Belg., 28.4.19.)

Cordes. Converting heavy hydrocarbons into lower-boiling lighter products. 19,616. July 8. (Ger., 28.7.14.)

Cummins. Vertical gas-retort settings. 18,825. July 6.

Dempster, Knight, and Siddall. Combined coal carbonising and gas-making plant. 18,076. July 2.

Deuts. Erdöl A.-G., Koettwitz, and Seidenschmur. Obtaining lubricating oils from bituminous or asphaltic materials. 18,874-5. July 6. (Ger., 6.11 and 3.3.16.)

Evans, Hollings, Stanier, and South Metropolitan Gas Co. Removing sulphur from gases. 20,332. July 9.

Ges. f. Maschinelle Druckentwässerung. Drying raw peat. 17,612. June 28. (Ger., 2.1.14.)

Ges. f. Maschinelle Druckentwässerung. Utilising coal slimes. 17,613. June 28. (Ger., 2.1.14.)

Goldschmidt A.-G. Separate recovery of constituents of distillation gas from fuel. 18,266. July 2. (Ger., 26.10.17.)

Haersolte van Haerst. Coke-ovens. 19,308-10, 19,743-4. July 7 and 8. (Ger., 14.7, 15.8, 1.3.16, 31.3.17, 1.10.18.)

Hollings, and South Metropolitan Gas Co. Removing sulphur from gases. 20,333. July 9.

Hunt. 17,940-1 and 18,855-6. See XX.

Hyde. Steaming horizontal gas retorts. 18,102. July 2.

Klönne. Gas-producer furnaces. 17,781. June 29. (Ger., 12.4.20.)

Linck. Gas-producers. 20,166. July 9. (Ger., 2.2.18.)

Nelson. Cracking hydrocarbon oils etc. 18,524. July 3.

Pintsch A.-G. Gas-producers. 18,863 and 19,478. July 6 and 8. (Ger., 26.3.14 and 30.4.18.)

Standard Oil Co. Obtaining products from petroleum. 18,574. July 5. (U.S., 20.10.13.)

Standard Oil Co. Distilling hydrocarbons. 19,709. July 8. (U.S., 26.6.14.)

Still. Purifying coal gas. 19,518. July 8. (Ger., 10.12.17.)

Still. Separating constituents from coke-oven etc. gases. 19,740. July 8. (Ger., 1.11.18.)

Still. Recovery of ammonia from products of distillation of coal etc. 19,739. July 8. (Ger., 3.12.18.)

Still. 19,126. See VII.

Strache. Preparation of acids from petroleum etc. 19,958. July 9. (Austria, 20.1.17.)

Teichner. Oxidising hydrocarbons. 20,277. July 9. (Austria, 15.5.19.)

Verity. Gas-producers. 18,457. July 3.

Welford. Treatment of oil shale etc. 17,814. June 30.

COMPLETE SPECIFICATIONS ACCEPTED.

21,389 (1918). Colman and Yeoman. Extraction and recovery of carbon bisulphide. (145,099.) July 7.

1425-6 (1919). Perry. Apparatus for distilling carbonaceous material. (145,101-2.) July 7.

4576 (1919). Hood. Purification of petroleum oils. (145,818.) July 14.

7182 (1919). Harger. Gas-producers. (145,136.) July 7.

7898 (1919). Antrobus. Gas-producers. (145,164.) July 7.

7986 (1919). Brockway. Apparatus for washing and scrubbing coal gas. (145,856.) July 14.

8193 (1919). Spicer (Wells). Gas-producers. (145,873.) July 14.

8627 (1919). Forward. Process of refining oil by distillation. (145,894.) July 14.

9686 (1919). Rock. Extracting hydrocarbons from coal etc. (145,906.) July 14.

9722 and 16,961 (1919). Forwood and Taplay. Treatment of hydrocarbons. (145,198.) July 7.

13,733 (1919). Gibson and Wyman. Production of enriched water-gas. (145,947.) July 14.

15,124 (1919). U.S. Industrial Alcohol Co. Motor fuel for aeroplane and other motors. (128,915.) July 14.

728 (1920). Crowther. Furnace or kiln for burning spent iron oxide. (145,366.) July 7.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

British Dyestuffs Corporation, Green, Napier, and Porter. Manufacture of phthalic acid and phthalic anhydride, and catalyst for use therein. 19,210. July 7.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of pyridine bases. 18,758, 18,943, 19,128. July 5, 6, 7. (Ger., 22.6.17, 30.8 and 23.12.18.)

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of anthraquinone derivatives. 18,944 and 19,519. July 6 and 8. (Ger., 11.7.18, 11.3.20.)

Friederich. Manufacture of trinitroresorcin. 18,362. July 2.

Juer and Smeu. Machine for nitrating etc. 20,026. July 9. (Hungary, 18.11.16.)

Melamid. Converting tar oils into neutral oils for lubricating. 18,833. July 6. (Ger., 11.3.19.)

Phillipson. 19,913. See XIX.

Schroeter. Hydrogenation of naphthalene. 19,394, 19,409, 19,449. July 8. (Ger., 24.2.15, 7.12.15, 13.5.16.)

Schroeter, and Tetralin Ges. Hydrogenation of naphthalene. 19,514 and 19,750. July 8. (Ger., 1.8.16.)

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

A.-G. f. Anilinfabr. Manufacture of dyestuffs of the acridine series. 18,202. July 2. (Ger., 22.4.15.)

British Dyestuffs Corp., Levinstein, and Imbert. Manufacture of phenylglycine or compounds thereof. 18,278. July 2.

Cassella und Co. Manufacture of vat dyestuffs. 19,693-4. July 8. (Ger., 4.7.18 and 24.3.19.)

Cassella und Co. Manufacture of a colour of the anthraquinone series. 20,256. July 9. (Ger., 15.3.15.)

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of azo dyestuffs. 18,760-1. July 5. (Ger., 30.6 and 23.4.14.)

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

- Carmuel (Bayer u. Co.). Protecting wool etc. from moth. 17,607. June 28.
 Cellon-Werke. Production of moulded articles from cellulose acetate. 19,957 and 20,278. July 9. (Ger., 25.1.19.)
 Deutsch-Koloniale Gerb- u. Farbstoff-A.-G. 19,154. See XV.
 Enge. Manufacture of fibrous material from wood etc. 18,503. July 3.
 Ges. f. Verwertung Chem. Produkte. Obtaining balloon materials etc. 17,638. June 29. (Ger., 21.8.17.)
 Hottenroth and others. Treatment of artificial threads etc. 19,315. July 7. (Ger., 7.10.18.)
 Hottenroth and others. 19,314. See XVII.
 Humphrys. Treating flax straw. 17,616. June 28.
 Jeroch and others. Utilising spent sulphite cellulose lyes. 18,477. July 3. (Ger., 24.1.17.)
 Johnston and Sutherland. Degumming and cleansing vegetable matter from fibres. 19,412. July 8.
 Moeller. Treatment of cellulose. 17,776-7. June 29. (Ger., 22.8.18 and 24.2.19.)
 Müller. Manufacture of artificial threads, sheets, etc. from viscose. 17,806. June 28. (Ger., 6.9.18.)
 Soc. Suisse des Ferments. Degumming textile materials. 17,721. June 29. (Fr., 30.6.19.)
 Verwertung Inlandischer Produkte Ges. Treating water reeds etc. for textile purposes. 19,460. July 8. (Ger., 20.12.16.)
 Wohl. 18,528 and 18,744. See XVII.
 Wolkinson. Treatment of vegetable fibre. 19,072. July 7. (Fr., 17.4.19.)
 Zellkoll Ges. Sizing paper pulp. 18,495. July 6. (Ger., 11.8.16.)
 Zellkoll Ges. Sizing paper, pasteboard, etc. 18,949. July 6. (Ger., 7.12.15.)
 Zellstoff-fabrik Waldhof. Treatment of wood etc. 19,313. July 7. (Ger., 19.10.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 8559 (1914). Govaerts and Dryepont. Treatment of ramie, flax, hemp, etc. plants. July 7.
 29,043 (1919). Watremez. Securing vegetable fibres to accelerate and facilitate subsequent bleaching. (135,516.) July 7.

VI—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

- Bennert. Preparation of dye-vats. 17,945. June 30. (Ger., 21.12.15.)
 Boardman and Petrie. Dyeing apparatus. 17,823. June 30.
 Carl, and Jager Ges. Producing marbled effects on textiles. 20,097. July 9. (Ger., 13.5.19.)
 Farb. vorm. Meister, Lucius, u. Brüning. Printing with insoluble dyestuffs. 19,129. July 7. (Ger., 15.1.19.)
 Freiburger. Treatment of fabrics. 17,503. June 28. (Ger., 13.2.17.)
 Kaufmann. Apparatus for dyeing linen etc. 20,056. July 9. (Fr., 18.10.13.)
 Mohr and others. Bleaching-device. 20,250. July 9. (Ger., 14.9.16.)
 Ornstein. Bleaching vegetable substances. 19,042. July 6. (U.S., 2.12.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 6817 (1919). Hunt. Apparatus for bleaching treatment of open fabrics. (145,113.) July 7.
 14,232 (1919). Calico Printers' Assoc., Rouse, and Nelson. Printing cotton fabrics and yarns. (145,240.) July 7.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

- Aragay and Bonneau. Simultaneous production of caustic soda and hydrochloric acid. 18,267. July 2. (Spain, 30.1.19.)
 Bea. Manufacture of copper sulphate. 19,675. July 8. (Fr., 3.8.17.)
 Bea. 20,316. See X.
 Bengough. Opening up water-insoluble compounds of the alkalis, alkaline-earths, metals, etc. 18,311. July 2. (Ger., 23.2.18.)
 Chem. Fabr. Rhénania, Grob, and Stuer. Manufacture of nitrogen-containing products from acetylene and ammonia. 19,039. July 6. (Ger., 20.11.13.)
 Clerc and Nihoul. 18,398. See X411.
 Collin A.-G. Producing ammonium sulphate from cyanogen compounds. 17,974. June 30. (Ger., 17.5.19.)
 Coppet. 19,630. See XIII.
 Dempster, Knight, and Siddall. Plant for making hydrogen. 18,438. July 3.
 Dumont. Lime kilns etc. 17,855. June 30.
 Forster und Co. Manufacture of sulphuric acid. 19,121. July 7. (Ger., 24.6.18.)
 Frischer. Obtaining oxides of nitrogen from ammonia. 17,522. June 28. (Ger., 23.11.16.)
 Heibronner. 20,269. See XIII.
 Howorth (Akt. Høyangsfaldene Norsk Aluminium Co.). Preparation of aluminium oxide. 17,765. June 29.
 Jaubert. Manufacture of hydrogen. 19,483. July 8. (Fr., 9.3.18.)
 Kersten. Decomposition of alkali chlorides. 19,459. July 8. (Ger., 10.5.16.)
 Mitsubishi Kogyo Kabushiki Kaisha. Synthetic production of cyanides. 18,674. July 5. (Japan, 7.7.19.)
 Mond (Metallbank u. Metallurg. Ges.). Production of zinc oxide. 19,959. July 9.
 Robertson. Obtaining volatilisable metal oxides. 19,388. July 8. (U.S., 16.12.18.)
 Sonneck, and Unione Italiana fra. Consum. o Fabric. di Concimi e Prod. Chimici. Manufacture of sulphuric acid. 18,746. July 5.
 Still. Treating crude gas liquor to obtain ammonia solution. 19,126. July 7. (Ger., 6.12.15.)
 Still. 19,739. See II.
 Verein Chem. Fabr. Mannheim. Manufacture of hydrofluoric acid. 19,704. July 8. (Ger., 27.12.18.)
 Verein Chem. Fabr. Mannheim. Manufacture of sulphur dioxide. 19,705. July 8. (Ger., 8.8.19.)
 Westling. Production of manganese dioxide. 18,979. July 6. (U.S., 14.3.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

- 7403 (1919). Gould (Balfour-Guthrie Investment Co.). Producing cyanogen and ammonia. (145,824.) July 14.
 20,042 (1919). Thorssell and Lunden. Apparatus for making nitrogen products. (145,299.) July 7.
 26,253 (1919). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. Production of alumina. (134,531.) July 14.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- Feldenheimer, Plowman, and Schidrowitz. Treatment of clay. 20,339. July 9.
 Frink. Glass-melting furnaces. 18,118 and 18,136. July 2.
 Frink. Glass-annealing furnaces. 18,163. July 2.
 Grimwade, and Grimwades, Ltd. Composition and process for forming pottery moulds. 19,059. July 6.
 Kern. 18,755. See XI.
 King, King, and King and Son. Enamels. 17,519. June 28.

Moorshead. Glass furnaces. 19,427. July 8.
Pollak (Werke Gantenbach). Production of a substitute for black glass and insulating material. 17,750. June 29.

Rhodin. Preparation of sands for bleaching. 19,246. July 7.

Rosenthal. Colouring glass. 18,577. July 5. (U.S., 21.1.14.)

Schott u. Gen. Reducing size of bubbles in glass. 19,445. July 8. (Ger., 7.12.14.)

IX.—BUILDING MATERIALS.

APPLICATIONS.

Blériot. 19,749. *See* XI.
Bub. Preserving wood. 19,553 and 20,039. July 8 and 9. (Ger., 7.2.14 and 19.12.13.)

Crozier. Manufacture of cementitious articles. 17,566 and 17,730. June 28 and 29.

Dossetter. Wood substitutes etc. 19,725. July 8.

Link. Production of artificial trass. 17,693. June 29. (Ger., 5.11.18.)

Marcusson. Oil-proof concrete bodies. 17,944. June 30. (Ger., 1.7.18.)

Wade (Bombrini Parodi-Delfino). Manufacture of cements. 18,736-8. July 5.

COMPLETE SPECIFICATION ACCEPTED.

6004 (1916). Sanders and Sanders. Coating or impregnating cement, stone, bricks, etc. (145,806.) July 14.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Ampère Ges. Production of ferro-tungsten. 19,363. July 7. (Ger., 6.5.18.)

Ampère Ges. Production of ferro-chromium poor in carbon. 19,364. July 7. (Ger., 6.5.18.)

Avestaran é Irazusta. Conglomerating pulverulent mineral residues. 17,690. June 29.

Bea. Treatment of old brass to obtain copper and oxide of zinc. 20,316. July 9. (Fr., 3.8.17.)

Bensa. Medium for preventing oxidation of iron etc. 19,841. July 9. (Ital., 5.11.18.)

Bonnard. Refining tin and antimony. 18,179. July 2. (U.S., 15.3.20.)

Boorne. Electrode for depositing molten metal. 17,901. June 30.

British Thomson-Houston Co. Production of metal films. 20,032. July 9. (U.S., 6.6.14.)

Dagory. Removing copper deposits from bores of guns. 20,181 and 20,200. July 9. (Fr., 19.6 and 11.10.17.)

Difenthaler. Production of grey cast iron. 19,988. July 9. (Ger., 9.5.16.)

Elmore. Extraction of lead and zinc from ores. 19,295. July 7.

Gauschemann. Smelting - furnaces. 20,007. July 9. (Ger., 9.9.15.)

Goldberg. Electrolytically working concentrated ores or alloys containing copper and nickel. 17,760. June 29. (Ger., 9.7.18.)

Grinlinton. Coating metals. 18,692. July 5. (Australia, 4.7.19.)

Hackspill and Staehling. Manufacture of alkali metals. 20,023. July 9. (Fr., 5.11.13.)

Lancaster. Removing iron etc. from residues or waste. 18,531. July 5.

Lance. Extraction of metal in the form of oxide from pyritic ores. 18,380. July 2. (Fr., 16.5.16.)

Maddick and Williams. Manufacture of zine powder. 19,260. July 7.

Manuf. de Prod. Chimiques du Nord. Removal of dust from gases from ore-roasting. 18,964. July 6. (Ger., 6.5.14.)

Marks (Ore Roasting Development Co.). Treating ores. 18,967. July 6.

Maschinenfabr. Esslingen. Protecting iron alloys against burning when smelted. 17,525. June 28. (Ger., 19.11.17.)

Metallbank u. Metallurg. Ges. Lithium-aluminium alloy. 19,956. July 9. (Ger., 15.2.19.)

Metallbank u. Metallurg. Ges. Furnace for annealing metals. 20,156. July 9. (Ger., 14.3.19.)

Metallind. Schiele u. Bruchsal. Production of aluminium castings. 18,712 and 19,720. July 5 and 8. (Ger., 16.12.18, and 19.3.19.)

Milliken. Alloys. 19,013-4. July 6.

Otsuka. Apparatus for concentrating ores by flotation. 18,378. July 2. (Ger., 30.12.17.)

Schaufelberg. Compound for hardening iron and steel. 18,300. July 2.

Schlotter. Electrolytic production of tin deposits. 20,248. July 9. (Ger., 15.3.17.)

Tashero. Process for carburising steel and iron. 18,628. July 5. (Japan, 13.8.18.)

Teichner. Manufacture of nickel catalyst. 18,394. July 2. (Ger., 10.11.16.)

Zilewski. Zinc-extracting furnaces. 20,131. July 9. (Ger., 28.3.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

7111 (1919). Bloxam (Soc. Anon. des Usines Guilini). Increasing hardness and tenacity of metals. (145,129.) July 7.

7956 (1919). Wood, and Minerals Separation, Ltd. Concentration of ores. (145,852.) July 14.

8165 (1919). Minerals Separation, Ltd. (Emerson). Concentration of ores. (145,870.) July 14.

11,688 (1919). Sulman and Ballantine. Production of ferro-alloys. (145,925.) July 14.

14,094 (1919). Farmer. Alloy. (145,956.) July 14.

21,697 (1919). Gaskill. Crucible and like furnaces. (132,266.) July 14.

24,731 (1919). Stenquist. Metal alloy for armouring electric cables. (136,143.) July 7.

24,851 (1919). McLain and Carter. Open-hearth furnaces. (146,020.) July 14.

1829 (1920). Honhorst and Sofge. Steel alloys. (138,327.) July 14.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Blériot, Ltd. Manufacture of electrical insulating cement. 19,749. July 8. (Fr., 8.11.17.)

Boorne. 17,901. *See* X.

Brown. Electrostatic separation of finely divided discrete material. 19,159. July 7.

Champion Ignition Co. Insulating material. 18,843. July 6. (U.S., 22.8.17.)

Fery. Primary batteries. 19,942. July 9. (Fr., 1.12.14.)

Gef. f. Torfisolation. Manufacture of insulating bodies from peat. 20,103. July 9. (Ger., 31.8.15.)

Goldberg. 17,760. *See* X.

Kern. Manufacture of fireproof insulating material from clay etc. 18,755. July 5.

Miles. Electric furnaces. 18,958-9. July 6. (U.S., 25.1.18.)

Mond (Internat. Precipitation Co.). Apparatus for electrical treatment of gases. 17,744. June 29.

North. Electrically separating dust from gases and vapours. 17,723. June 29. (Ger., 27.8.17.)

Pollak. 17,750. *See* VIII.

Rickets. Electrically inducing chemical action. 18,627 and 19,549. July 5 and 8.

Schlotter. 20,248. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

8795 (1919). Steiger. Electric furnaces. (125,391.) July 14.

18,004 (1919). Piquerez. Electric furnace. (132,232.) July 14.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Blichfeldt. 17,784. *See* XIX.

Dorr Co. Treatment of soapy liquors. 19,251. July 7. (U.S., 1.7.19.)

Eisenstein, and Schlicht A.-G. Oxidation of oils. 19,634 and 20,202. July 8 and 9. (Czecho-Slov., 3 and 16.4.19.)

Elektro-Osmose A.-G. Purifying glycerin etc. 18,752. July 5. (Ger., 17.1.19.)

Faitelowitz. 20,070. *See* XV.

Imhausen. Production of soap powder. 18,879. July 6.

Imhausen. Washing medium. 20,213. July 9. (Ger., 10.12.15.)

Miles. Manufacture of emulsified products. 17,762. June 29. (U.S., 10.1.19.)

Reichsausschuss f. Pflanzliche u. Tierische Oele u. Fette Ges. Production of fat. 18,478. July 3. (Ger., 10.5.15.)

Rogers. Extraction of oils from fatty substances. 19,883. July 9. (U.S., 7.3.19.)

Soc. Rocca, Tassy, et de Roux. Neutralising oils and fats. 17,539 and 17,540. June 28. (Fr., 13.11.19 and 3.5.20.)

Soc. Gén. d'Evaporation. Treating residual waters containing fatty and soapy matters. 19,002. July 6. (Fr., 9.3.14.)

Soc. Gén. d'Evaporation. Decomposition of soapy waters. 19,003. July 6. (Fr., 9.3.14.)

Tseng. Manufacture of transparent soap 18,050. July 2.

Wado (Ordbrown). Treatment of oils and fats. 18,399. July 2.

Watkins (Egestorff). 18,461. *See* XIX.

Wilbuschewitsch. Continuous extraction of oil etc. 19,748. July 8. (Gr., 12.6.19.)

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Badische Anilin u. Sodafabr. Manufacture of artificial resins. 18,617. July 5. (Ger., 13. 6.19.)

Bucherer. Production of derivatives of condensation products of formaldehyde and phenols. 20,041 and 20,286. July 9. (Ger., 10.6.18 and 22.3.19.)

Clere and Nichoul. Manufacture of zinc sulphide. 18,398. July 2. (Fr., 20.5.19.)

Coppet. Manufacture of anhydrous zinc sulphide. 19,630. July 8. (Fr., 11.9.16.)

Dahl. Apparatus for manufacture of white lead. 18,079. July 2.

Filhol. Manufacture of varnishes etc. 19,238. July 7. (Fr., 26.6.19.)

Helbronner. Manufacture of zinc sulphide. 20,269. July 9. (Fr., 16.10.16.)

Jerome. Rendering painted materials impervious to moisture. 18,900. July 6. (Ital., 13.6.19.)

Lance. Manufacture of ultramarine blue and lacquered colours. 18,389. July 2. (Fr., 15.3.19.)

Miles. Manufacture of products from resins. 17,762. June 29. (U.S., 10.1.19.)

Mond. 19,959. *See* VII.

Nishizawa and Shibata. Drying Japanese lacquer. 18,370. July 2. (Japan, 29.4.19.)

Plöniss u. Co. Preparation of fireproof and waterproof paint. 19,828. July 9. (Ger., 16.9.16.)

Thompson. Making white lead. 19,755. July 8. (Ger., 13.10.14.)

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Goodyear Tire and Rubber Co. Manufacture of rubber products. 18,915 and 18,919. July 6. (U.S., 29.5.17 and 25.10.18.)

Haddan (Waitz). Recovering caoutchouc and textile from rubber fabric. 20,050. July 9.

Kendall and Thomson. Preparation and manipulation of rubber prior to vulcanisation. 18,421. July 3.

Tilche. Vulcanisation of rubber. 20,267-8. July 9. (Fr., 18 and 11.7.19.)

Wade (Goodyear Tire and Rubber Co.). Manufacture of rubber products. 18,916 and 18,920. July 6.

Wade (Goodyear Tire and Rubber Co.). Process of vulcanising caoutchouc. 18,917-8. July 6.

Waitz. Recovering rubber and textile material from rubber fabric. 19,585. July 8. (Ger., 5.7.17.)

COMPLETE SPECIFICATION ACCEPTED.

15,121 (1919). Marks (Acushnet Process Co.). Reclaiming rubber etc. from fabrics coated therewith. (145,251.) July 7.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Badische Anilin u. Sodafabr. Manufacture of tanning preparations. 18,467. July 3. (Ger., 19.2.19.)

Breuer. Manufacture of leather. 18,083. July 3. (Ger., 14.12.17.)

Carmichael and Ockleston. Unhairing hides. 18,006. July 2.

Chem. Fabr. Worms. Manufacture of tanning agents. 20,027. July 9. (Ger., 20.7.16.)

Czechon. 19,477. *See* XIX.

Deutsch-Koloniale Gerb- u. Farbstoff A.-G., and Römer. Obtaining tanning materials from cellulose waste sulphite lyes. 19,154. July 7.

Faitelowitz. Extracting albumen and fat from bones. 20,070. July 9. (Ger., 13.2.19.)

Knorr. Glues. 20,139 and 20,140. July 9. (Ger., 13.8.17 and 20.9.18.)

Korn. Leather substitute. 19,964. July 9. (Fr., 9.5.19.)

Tatham. Manufacture of tanned and rubberised leather. 18,763. July 5.

Vos. 19,827. *See* XVI.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Akt.-Ges. f. Anilinfabr. Manufacture of artificial fertilisers. 17,608 and 17,720. June 28 and 29. (Ger., 29.1 and 16.3.18.)

Chem. Fabr. Rhenania, and Voerkelius. Manufacture of manures. 20,170. July 9. (Ger., 31.5.18.)

Chem. Fabr. Rhenania, and Voerkelius. Nitric acid superphosphate. 20,171. July 9. (Ger., 12.4.19.)

Lidholm and others. Producing cyanamide from calcium cyanamide. 17,983. June 30. (Sweden, 19.9.19.)

Vos. Manufacture of manures from waste leather. 19,827. July 9. (Belg., 17.12.13.)

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Betavit Ges. Preparation of sugar beets etc. 19,707. July 8. (Ger., 13.12.17.)

Hottenroth and others. Obtaining sugar etc. from wood etc. 19,314. July 7. (Ger., 18.4.17.)

Wohl. Converting cellulose materials into soluble carbohydrates. 18,526. July 3. (Ger., 14.3.17.)

Wohl. Saccharifying cellulose-containing materials. 18,741. July 5. (Ger., 7.4.17.)

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Dubourg. Brewing beer. 18,333. July 2. (Fr., 18.1.19.)

Fleischmann Co. Production of yeast. 20,293. July 9. (U.S., 7.1.19.)

Fleischmann Co., and Harrison. Production of yeast. 20,294. July 9.

Scherdel and Wohl. Production of yeast. 17,797. June 29. (Ger., 15.1.15.)

Vasseux. Production of yeast from peat. 19,515. July 8. (Fr., 19.1.18.)

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Beaumont, Goudie, and Harkness. Making of jams, jellies, etc. 18,890. July 6.

Bielmann and Bielmann. Manufacture of jellies from fruits etc. 19,887 and 20,352. July 9. (Ger., 24.11.16 and 14.3.19.)

Blichfeldt. Manufacture of margarine. 17,781. June 29.

Czochron. Obtention of albumen from leguminous seeds. 19,477. July 8. (Ger., 30.5.19.)

Elektro-Osmose A.-G. (Graf Schwerin Ges.). 17,609. See XX.

Elektro-Osmose A.-G. (Graf Schwerin Ges.). Process for obtaining the yellow and white constituents of eggs in a dry state. 18,947. July 6. (Ger., 9.1.18.)

Matzka. Utilisation of fruit etc. refuse. 19,881. July 9. (Ger., 8.6.18.)

Philpison. Coal tar disinfectants. 19,913. July 9. (U.S., 15.3.18.)

Ricciardi. Drying-kilns for alimentary pastes etc. 17,876. June 30.

Sykes. Apparatus for dehydrating food products. 18,852. July 6. (U.S., 4.2.18.)

Townsend. Manufacture of food. 19,605. July 8.

Vollbrot Patent Verwertungs-Ges. Process for manufacture of baked articles direct from corn. 18,344. July 2. (Ger., 3.10.14.)

Vollbrot Patent Verwertungs-Ges. Manufacture of food. 18,345. July 2. (Ger., 8.9.17.)

Vollbrot Patent Verwertungs-Ges. Apparatus for manufacture of baked articles direct from corn. 19,041. July 6. (Ger., 9.11.15.)

Watkins (Egestorff). Process for manufacture and preservation of cattle food, fish-livers, and oil therefrom. 18,461. July 3.

Wolff. Production of germ-free air. 19,499. July 8. (Ger., 12.9.17.)

COMPLETE SPECIFICATION ACCEPTED.

19,049 (1919). Adams. Separation of sludge and scum from sewage and other liquids. (145,291.) July 7.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Akt.-Ges. f. Anilin-Fabr. Manufacture of oxyarylaldehydes. 17,719. June 29. (Ger., 6.2.18.)

Bader, British Cellulose and Chemical Manufacturing Co., and Nightingale. Manufacture of aromatic derivatives. 18,114. July 2.

Bader, British Cellulose and Chemical Manufacturing Co., and Nightingale. Manufacture of alkyl derivatives. 18,115. July 2.

Bergius, and Goldschmidt A.-G. Production of ethylene chloride. 19,963. July 9. (Ger., 29.2.16.)

Boehringer Sohn. Process for obtaining effective ingredients of lobelia. 17,795-6. June 29. (Ger., 4.4 and 2.9.14.)

British Dyestuffs Corporation, and others. 19,210. See III.

Du Pont de Nemours and Co. Process for production of alkyl anilines. 18,085. July 2. (U.S., 7.7.17.)

Elektro-Osmose A.-G. (Graf Schwerin Ges.). Process for preparing proteins charged with immune substances. 17,609. June 28. (Ger., 11.7.18.)

Elektro-Osmose A.-G. (Graf Schwerin Ges.). Process for purifying glycerin etc. 18,752. July 5. (Ger., 17.1.19.)

Ellis (Soc. Chim. Usines du Rhône, anc. Gilliard, Monnet et Cartier). Manufacture of oxalaldehydes etc. 19,208. July 7.

Faitelowitz. 20,070. See XV.

Farbw. vorm. Meister, Lucius, n. Brüning. Manufacture of arseno compounds of the pyrazolone series. 18,759. July 5. (Ger., 15.12.17.)

Goldschmidt A.-G., and Matter. Production of ethylene chloride. 19,962. July 9. (Ger., 22.5.15.)

Grunstein. Manufacture of butyric aldehyde and butyl alcohol from erotonic aldehyde. 19,152. July 7. (Switz., 4.1.19.)

Grunstein. Manufacture of aldol from acetaldehyde. 19,153. July 7. (Switz., 18.3.19.)

Hunt. Production of reactive acid liquor, alcohols, esters, etc. from gaseous hydrocarbons. 17,940. June 30.

Hunt. Production of esters etc. from olefines. 17,941. June 30.

Hunt. Conversion of secondary alcohols into ketones. 17,942. June 30.

Hunt. Production of alcohols, esters, etc. from still gases of petroleum. 18,855. July 6. (U.S., 20.3.17.)

Hunt. Production of alcohols, esters, etc. from gaseous hydrocarbons. 18,856. July 6. (U.S., 11.3.19.)

Imray (Soc. of Chem. Ind. in Basle). Manufacture of aralkyl esters of 2-phenylquinoline-4-carboxylic acid. 18,756. July 5.

Kolshorn. Process for manufacture of salts of compounds of tannic or gallic acids and lactic acid. 17,554. June 28. (Ger., 13.6.19.)

Kolshorn. Manufacture of derivatives of *p*-aminophenol and of its *O*-alkyl ethers. 17,780. June 29. (Ger., 13.6.19.)

Matter. Production of polyvalent alcohols. 19,960-1. July 9. (Ger., 8.12.13 and 21.4.15.)

Tweedale and Tweedale. Manufacture of perfume and flavouring essences etc. 17,860. June 30.

Welmer. Manufacture of fumaric acid. 18,400. July 2. (Ger., 28.9.15.)

White (U.S. Sanitary Specialties Corp.). Decolorising materials. 18,351. July 2.

COMPLETE SPECIFICATION ACCEPTED.

8173 (1919). Confectionery Ingredients, Ltd., Matthews, King, and Kane. Manufacture of proto-catechuic aldehyde. (145,871.) July 14.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Shepherd. Method of obtaining a yellow separation print in colour photography. 17,892. June 30.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Buck. Liquid air for use as an explosive. 20,118. July 9.

Dubrisay. Manufacture of damp-proof matches. 18,195. July 2. (Fr., 3.7.19.)

Pinder and Semple. Manufacture of explosive. 19,115. July 7.

Von Herz. Explosives. 18,183. July 2. (Austria, 25.1.19.)

Wohl. Explosives. 17,605, June 28. 17,749, June 29. 18,711, July 5. (Ger., 14.1. and 1.3.19, and 9.1.20.)

APPLICATIONS.

Siemens u. Halske A.-G. Photometric apparatus. 19,191. July 7. (Ger., 8.7.19.)

Simmance. Calorimetric apparatus. 18,762. July 5.

I.—GENERAL; PLANT; MACHINERY.

Treating volatile liquids with other liquids; Process for —. [Refining petroleum with sulphuric acid.] P. Mallet. Chim. et Ind., 1920, 3, 608.

To avoid loss of the volatile liquid when treated with another liquid with air agitation, and to prevent formation of explosive vapours, the process is carried out in a closed vessel. The air-vapour mixture may be utilised again for agitation, any corrosive effect of the vapours being overcome by passing the mixture through suitable absorbers before re-introducing it into the reaction apparatus.—W. J. W.

PATENTS.

Absorption, reaction, distillation, rectification, and like columns. L. Gay. E.P. 141,371, 7.3.19.

The plates of the column are traversed by two sets of vertical tubes, for passage of liquid and gas or vapour respectively, so distributed that on one and the same straight line there are alternately two gas tubes and one liquid tube, the former being located at the angles and the latter at the centres of regular hexagons. The gas tubes project from the upper surface of the plate; each is covered with a hood provided with openings in contact with the plates, while the liquid tubes project from the two surfaces of the plate, the portion projecting from the upper surface being slightly shorter than the gas tubes, while the portion projecting from the lower surface extends almost to the next lower plate. A common sleeve surrounds the lower part of a liquid tube of an upper plate and the upper part of a liquid tube of a lower plate, the sleeves being open at their upper ends and provided towards the top with long narrow vertical slots, and in their lower part with openings where they join the lower plates. The space between the plates is provided with filling material up to the level of the upper ends of the slots in the sleeves surrounding the liquid tubes.—J. S. G. T.

Filter. D. A. Corey. U.S.P. 1,295,006, 18.2.19. Appl., 7.5.17.

The filter is built up of a number of superposed sections each having a central tubular collar. A screen fits over the collar and extends radially outwards, the outer edge having an upright portion. A dished plate is also supported by the collar and extends outwards and upwards away from the screen; it is bent downwards at the circumference forming a perforated flange outside the screen. A filtering element is placed below each screen. Liquid enters from the interior of the collar, passes through perforations in the collar and upwards through the filter, into the chamber next above, and thence outwards through the perforated rim of the dished plate. The sections are easily separated for cleaning.—W. F. F.

Filter-press. H. T. Shriver. U.S.P. 1,342,829, 8.6.20. Appl., 22.9.19.

Is a plate and frame filter press in which each alternate plate is connected with a wash channel, automatic non-return valves are provided in the plates to prevent liquor flowing into the wash channel in the direction opposite to the wash water.—B. M. V.

Filter [press]. E. F. Atkins, Assr. to H. T. Shriver. U.S.P. 1,342,839, 8.6.20. Appl., 23.6.19.

Each plate of a plate and frame filter-press is provided with an outlet leading to the exterior, and a closed conduit extends along the plates and frames. By means of a multiple-way valve on each plate, the outlet to the exterior of the plate may be

opened and communication prevented between the outlet and the conduit; the outlet to the exterior of the plate may be closed, and the outlet connected with the conduit; or the outlet may be closed and communication between it and the conduit prevented.—J. S. G. T.

Filter. E. J. Sweetland, Assr. to United Filters Corp. U.S.P. 1,343,182, 8.6.20. Appl., 15.3.15. Renewed 6.6.19.

The filter itself is supported independently of its casing, which is formed in sections, and means are provided for moving the sections towards and away from the filter.—B. M. V.

Tunnel kiln. G. H. Benjamin. U.S.P. 1,294,756, 18.2.19. Appl., 21.5.17. Renewed 10.7.18.

The kiln combines the features of the "direct fire" and the "muffle" types, and means are provided for regulating the temperature at various points along its length. Two pairs of hot blast stoves are arranged one on either side of the kiln at the middle of its length, and hot air is delivered from them into longitudinal flues and thence through ports into the kiln. Combustion chambers are arranged on the inner side of the kiln walls, near the middle, and means may be provided for directing the combustion products through one of each of the opposed pairs of hot blast stoves to produce a still higher temperature at the middle zone of the kiln. Any desired variation in temperature along the length of the kiln may be produced by providing electrical heaters in the air supply flues and bringing one or more into operation. The passage of current through the heating coils may be controlled automatically by the movement of a truck through the kiln.—W. F. F.

Liquids [oil-water emulsions]; Separation of —. C. W. McKibben. U.S.P. 1,296,988, 11.3.19. Appl., 17.8.18.

An apparatus for separating the constituents of an emulsion, such as oil and water, comprises a tall, vertical cylinder provided with a fixed electrode composed of a series of wires forming an inverted cone, and a similar inner rotating electrode mounted on a concentric vertical shaft. The outer electrode and the casing are connected to one of the terminals of a high potential transformer of constant current type, and the inner electrode to the other terminal. The emulsion is passed continuously through the apparatus from top to bottom, and the separated liquids are drawn off through an outlet at the side, near the bottom. If a series of such separators be employed in parallel with a single transformer, the current, which is of predetermined value, is automatically divided between the separators as required by the condition of the liquid in each separator.

—W. F. F.

Pulverising frangible substances. G. A. Overstrom. U.S.P. 1,300,192, 8.4.19. Appl., 21.8.16.

MATERIAL to be pulverised is fed continuously into a rapidly rotating receptacle mounted on the upper end of a vertical shaft. Under the action of centrifugal force the material accumulates against the sides of the receptacle, leaving an inverted conical space in the centre, and any further material received then rides over the surface of the accumulated material, and is discharged over the rim of the receptacle. Wear of the rotating receptacle, except the rim, is thus avoided, and the rim is renewable when required. The material is thrown against an outer ring, having internal teeth, and is thereby pulverised, and, to prevent unequal wear of the ring, it may be partly rotated at intervals. The ring is built up of several superposed similar sections, so that when the central section becomes

worn the sections may be rearranged. Rotation of the material accumulated in the receptacle relatively to the latter is prevented by radial ribs below the normal surface of the material.—W. F. F.

Mixing and grinding apparatus. R. D. Maddox. U.S.P. 1,301,070, 15.4.19. Appl., 26.11.18.

A GRINDING receptacle is constructed of a distorted cylindrical shape. The two ends are elliptical, with the major axes of the two ellipses at right angles to one another, and the side walls of the cylinder form a continuous surface between the two ellipses. A number of such cylinders rest with their peripheral surfaces on a pair of long, horizontal supporting-rollers, so that when the rollers are rotated the receptacles are also rotated and simultaneously rocked from end to end so as to mix and grind the material which is placed within them.

—W. F. F.

Centrifugal dryer. G. H. Elmore. U.S.P. 1,342,743, 8.6.20. Appl., 8.8.18.

THE basket of the rotor is double-walled, the inner wall being solid and the outer perforated. The material passes from an axial feed inlet through passages to the annular space, being assisted by plungers working across the outer ends of the passages.—B. M. V.

Pump [for corrosive liquors]. D. Farrand. U.S.P. 1,342,798, 8.6.20. Appl., 23.10.17.

A U-SHAPED pipe is filled in the bend and some distance up each limb with a liquid of greater sp. gr. than the liquid to be pumped. At the top of one limb is a trunk piston with a layer of oil under it, and at the top of the other limb are inlet and outlet valves and connexions for the liquid to be pumped.—B. M. V.

Separating suspended matter from gases; Means for —. W. A. Schmidt, Assr. to International Precipitation Co. U.S.P. 1,343,285, 15.6.20. Appl., 5.3.13.

THE apparatus comprises a longitudinal ionising portion, a charging electrode, and a collecting field-surface member, the field surface being substantially parallel to the ionising chamber.

—J. S. G. T.

Separating suspended particles from gases; Apparatus for —. W. A. Schmidt and G. C. Roberts, Assrs. to International Precipitation Co. U.S.P. 1,343,482, 15.6.20. Appl., 23.3.14.

A COLLECTING electrode presenting a relatively extended surface is arranged within a precipitation chamber parallel to the direction of the gas current therein. The collecting electrode may consist of a perforated screen or a number of screens arranged in parallel planes, discharge electrodes of relatively small surface being interposed. The collecting electrode may be provided with flanges to act as baffles to the gas current.—J. S. G. T.

Refrigerating apparatus. C. Delaygue. E.P. 29,635, 23.12.13.

Condensing apparatus [for refrigerating machines]. J. McOustra. E.P. 144,413, 26.3.19.

Corrosive fluid valves. Chemical Equipment Co., Asses. of H. E. La Bour and G. A. Grassby, jun. E.P. 124,445, 13.3.19. Conv., 13.3.18.

Rotary furnaces, retorts, and the like [; Driving mechanism for —]. E. H. Summers and E. S. Whittard. E.P. 144,815, 21.3.19.

Froth or scum; Method and apparatus for suppressing the formation of — when boiling liquids. E. Wirth-Frey and E. Jenny-Henz. E.P. 121,293, 5.12.18.

II.A.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Oxidation of —. M. Godchot. Comptes rend., 1920, 171, 32-34.

THE coal used contained 37.40% of volatile matter, 58.60% of fixed carbon, and 4% of ash. The ash-free material contained 83.59% C, 5.78% H, 10.67% O+N. The coal gave 22.63% of pyridine extract, which contained 83.45% C, 5.84% H, 10.51% O+N. When heated in the air at 100° C. for one month the original coal gained 3.15%, the extract 1.22%, the residue 1.99%, and a mixture of the residue and extract gained 3.20%. These results do not appear to be consistent with bacterial action being the cause of the slow oxidation of coal.—W. G.

Coal analysis; Notes on —. F. S. Sinnatt. Bull. 4, Lancs. and Cheshire Coal Res. Assoc., 1920. 38 pp.

APART from methods for the sampling, and proximate and ultimate analysis of coal, the bulletin contains information on the subject of the inorganic partings which occur in most bituminous coals, and on the fusibility of coal ash (*cf.* Cobb, J., 1904, 11). Carbonates in coal may be determined by a modification of the Pettenkofer method, described previously (Analyst, Apr., 1913). The agglutinating power (Grounds and Sinnatt, J., 1920, 83 r) and the increase in volatile matter due to the addition of inert matter, such as stone-dust (following abstract) should also be determined. A summary is given of eight results obtained by carrying out the standard volatile matter test in crucibles of different materials, showing the figures to vary between 28.4% and 36.1% for one coal and 31.9% and 37.8% for a second coal. A method of calculating the oxygen content of the coal substance is given.—A. G.

Coal; Influence of the addition of inert matter upon the volatile matter evolved when — is heated. F. S. Sinnatt and A. Grounds. Bull. 3, Lancs. and Cheshire Coal Res. Assoc., 1920. 14 pp.

THE effect of the degree of fineness of the coal, the addition of inert matter in varying proportions, and the fineness of the inert matter added upon the percentage of volatile matter evolved when coal is heated has been studied. Contrary to Somermeier (J. Amer. Chem. Soc., 1916, 26, 1002), the authors found that fine coal evolves rather more volatile organic matter than coarse coal. The inert matter added to the coal was gas-carbon, graded to varying degrees of fineness. With a mixture of 1 pt. of coal to 4 pts. of gas-carbon, carbonised under standard conditions, varying the size of the gas-

carbon produced very little change in the percentage of volatile matter evolved. On adding the gas-carbon to the coal in varying proportions, however, and carbonising under the same conditions, the percentage of volatile matter increased with the addition of gas-carbon up to a point at which there were 20 pts. of gas-carbon to 1 pt. of coal. The results are published for eight typical Lancashire coals, the volatile matter evolved having increased from 31.2 to 41.0% (Arley), from 38.0 to 50.0 (Bacon Mine), from 35.3 to 46.4 (Garswood 9ft.), from 33.9 to 43.2 (Hall Hole), from 27.3 to 32.3 (Mountain Mine), from 31.8 to 43.0% (Pemberton 2 ft.), from 31.7 to 45.3 (Ravine Mine), and from 28.0 to 30.0 (Hoo Cannel). The bearing of these results on the subject of stonedusting in mines and on the "sandwich" system of utilising coal and coke for steam-raising is discussed.—A. G.

Fuels; Practical value of —. E. Damour, *Comptes rend.*, 1920, 170, 1578–1581.

IN determining the practical value of a fuel it is necessary to take into account several factors in addition to the calorific value. The relative practical value of two fuels is the inverse of the weights of the two fuels which will just replace one another and give the same effect in a given furnace. A close approximation to the practical value is given by $V = Pf(0 - t)[1 + a(0 - t)] \pm M$, where P is the calorific value of the fuel used, 0 is the temperature of combustion, t the temperature of the material heated, and M represents all such factors as the cost of working the fuel, gasification, pulverisation, crushing, management of the fires, etc.—W. G.

Heavy oil fuel; Industrial use of —. E. Chabanier, *Chim. et Ind.*, 1920, 3, 566–575.

THE requirements as to viscosity, ignition temperature, and the amount distilled between certain temperatures are discussed. The author compares various types of solid fuel and gas furnaces, and describes their conversion into oil furnaces. In long-flame furnaces the consumption of oil is about one-third of the fuel consumption in a gas furnace. The oxidising effects of the flame can be reduced as desired.—W. J. W.

Gasoline; Methods of removing — from natural gas. R. P. Anderson, *J. Ind. Eng. Chem.*, 1920, 12, 547–549.

LEAN natural gas, yielding less than 0.5 gall. of gasoline per million cub. ft., is usually compressed for transport. The absorption method of removing gasoline has been used with gas containing less than 0.1 gall. per million cub. ft. Compression of moderately rich gas (0.5–3 galls. per million cub. ft.) will remove part of the gasoline, and the remainder may be recovered by refrigeration or absorption methods. Rich gas (more than 3 galls. per million cub. ft.) yields a larger proportion of its gasoline on compression, owing to the higher initial partial pressure of gasoline constituents, and but little more will be recovered by either refrigeration or absorption methods.—C. A. M.

Natural gas; Partial condensation of — at liquid air temperatures. J. Satterly, *Trans. Roy. Soc. Canada*, 1913, 13, [iii.], 109–121.

IN the preliminary analysis of natural gas for helium it is passed into a tube cooled with liquid air in which hydrocarbons condense. The condensed product is usually solid with Western Canadian gases and Texas gas, but liquid with most of the Ontario gases. The liquidity is due to dissolved ethane. The pressures during treatment show that some nitrogen probably dissolves in liquid methane or in the condensed solid. When the

liquid air cooling is removed and the condensed product allowed to warm up, instead of the pressure increasing regularly it sometimes rises to a certain point, halts for a time, and then suddenly diminishes for several cm., keeps steady for a time, and then gradually descends. It is thought that as the pressure rises some nitrogen is suddenly forced into solution. The reverse effects are often noticed on putting the tube again in liquid air. In some ways the sudden evolution or solution of nitrogen by liquid methane resembles the occlusion and spitting of oxygen by molten silver, and the effect must be kept in mind in the design of liquefaction plants, as a sudden evolution of gas may upset the balance in the rectifying column.

—J. R. P.

Methane-nitrogen; Composition of the vapour and liquid phases of the system —. H. A. McTaggart and E. Edwards, *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 57–66.

IN connexion with the extraction of helium from natural gas (cf. preceding abstract), the temperature-composition diagram for the system methane-nitrogen at atmospheric pressure was obtained, and the constants in the formula $\log r' = a + b \log r$, where r = ratio methane/nitrogen in the liquid, and r' the corresponding ratio in the vapour, determined as $a = -0.47$, $b = +0.85$.—J. R. P.

Methane and ethane; Latent heats of vaporisation of —. J. Satterly and J. Patterson, *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 123–127.

APPROXIMATE values of the latent heats of vaporisation of methane and ethane have been determined: methane 130 cal. per g.; ethane 260 cal. per g. (See J.C.S., Aug.)—J. R. P.

PATENTS.

Motor fuel for aeroplane and other motors. U.S. Industrial Alcohol Co., Assees. of W. T. Schreiber. E.P. 128,916, 16.6.19. Conv., 25.6.18.

THE fuel consists of 35–50% of an alcohol, e.g., ethyl alcohol, 25–35% of an aromatic hydrocarbon, e.g., benzol, and 20–40% of an ether, e.g., ethyl or butyl ether.—A. E. D.

Extracting oils and hydrocarbon material from shale and similar bituminous rocks [in situ]; Process for —. D. T. Day. U.S.P. 1,312,741, 8.6.20. Appl., 17.1.18.

THE volatile hydrocarbon material is volatilised from shale etc. *in situ* by pumping hot gases of combustion, substantially free from oxygen, down a borehole, the combined gases and vapour being led out of the borehole and afterwards separated.

—B. M. V.

Oil-still. W. M. Duncan. U.S.P. 1,342,947, 8.6.20. Appl., 10.9.17.

THE still contains intake and discharge manifolds near the bottom and top respectively. The manifolds are connected through a centrifugal pump within the still, whereby oil may be pumped from the bottom and discharged on to the surface of the oil in the still.—A. E. D.

Motor fuels and light paraffin oils from shale; Method of obtaining — and benzene, toluene, and solvent naphtha from coal. E. W. Thurlow. U.S.P. 1,343,100, 8.6.20. Appl., 28.8.17.

SHALE or coal is mixed with finely divided metal and with a substance which evolves carbon dioxide when heated, and then subjected to destructive distillation.—A. E. D.

Firing furnaces with powdered fuel; Apparatus for —. J. J. C. Brand. E.P. 144,763, 11.3.19.

Coke or the like withdrawing or extracting apparatus as applied to inclined and vertical carbonising and the like retorts and the like; Mechanically operated —. J. Mitchell. E.P. 144,952, 5.11.19.

Sulphonated products of mineral oils and process of producing same. Sulphonic acids of mineral oils and process of producing same. Alkali metal sulphate and process of producing same. W. J. Mellersh-Jackson. From Twitchell Process Co. E.P. 143,681—3, 5.4.19.

SEE U.S.P. 1,301,662, 1,303,779, and 1,301,663; J., 1919, 471 A, 545 A.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Adsorbing materials [charcoal and carbonised lignite]; Density of —. S. McLean. Trans. Roy. Soc. Canada, 1919, 13, [iii.], 197—199.

THE density was determined by the volumometer method, using helium as the filling gas, since it is not adsorbed at ordinary temperature. The following mean results were found:—Coconut charcoal (heated to 400° C.), 1.53; lignite carbonised at 350°, 1.33; lignite carbonised at 450°, 1.46; lignite carbonised at 550° C., 1.44.—J. R. P.

Inverted incandescence gas burner; A study of the —. C. Killing. Gas World, 1920, 72, 586—589.

By inserting very fine platinum wires at various points in the flames of an upright and an inverted Bunsen burner respectively, it was found that in each case the highest temperature of the flame occurs just at the tip of the small inner green cone of the flame. The heat produced in the primary combustion is proportional to the proportion of air in the primary mixture. These results have been applied in the design of a burner in which the primary air-gas mixture flows downwards out of the nozzle, and the mantle is brought very close to the small green inner cone of the flame. The lower end of the burner nozzle is provided with wire gauze or a perforated grid of metal, steatite, or magnesia. The mantle is small, hemispherical, and "spiderless," and retains its shape in use. The efficiency of the burner in the vertical direction is 0.69 l. per Hefner. Burners employing a magnesia grid at the bottom of the burner nozzle give 148.3 Hefners vertically, 123.5 Hefners at an angle of 45°, and 82.5 Hefners horizontally for an hourly consumption of 82.2 l. measured at 0° C. and 760 mm.

—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Paracoumarone resin. King and others. See XIII.

PATENTS.

Phenols and "other aromatic hydrocarbons"; Process of removing — from water or other liquids. R. M. Leggett, Assr. to Ozone Co. of America. U.S.P. 1,341,913, 1.6.20. Appl., 23.12.18.

THE liquid containing phenol is "coagulated," and after settling and removal of the deposit is treated with ozone.—W. H. C.

Sulphonating benzene. Barrett Co., Assees. of C. R. Downs. E.P. 122,169, 28.11.18. Conv., 5.1.18.

SEE U.S.P. 1,279,295—6 of 1918; J., 1918, 763 A.

Benzene etc. from coal. U.S.P. 1,343,100. See IIA.

IV.—COLOURING MATTERS AND DYES.

Cyanine dyes. I. Constitution of the isocyanines. W. H. Mills and R. S. Wishart. Chem. Soc. Trans., 1920, 117, 579—587.

THE oxidation of 1,1-dimethylisocyanine acetate with cold aqueous permanganate gave 1-methyl-2-quinolone and cinchonic acid methochloride in accordance with the equation:

$C_{21}H_{19}N_2X + 3O = C_{10}H_7ON + C_{11}H_{10}O_2NX$, and it is concluded that the constitution of the dye is expressed by the formula:

The possibility that the isocyanines are virtually tautomeric compounds is, however, admitted, and a reversal of the normal order of basicity of the nitrogen atoms obtaining in the case of the simpler isocyanines is probably brought about by negative substitution in the quinoline half of the molecule, e.g., in 1'-methyl-2'-phenyl-1-ethylisocyanine iodide.

—G. F. M.

Morinda citrifolia; Constituents of —. J. L. Simonsen. Chem. Soc. Trans., 1920, 117, 561—564.

THE material investigated was obtained by acidification of the cold-water extract of the sparingly soluble barium salt of morindin (cf. J., 1918, 685 A). The yellow precipitate thus obtained was a complex mixture containing much resinous matter, but rubiadin monomethyl ether and alizarin α -methyl ether were isolated from it. The former substance is the methyl ether of 1,3-dihydroxy-4-methyl-anthraquinone, and is identical with the substance obtained by Barrowcliff and Tutin from *M. longiflora*, and erroneously described by them as a 1,3-hydroxymethoxy-2-methylantraquinone. Alizarin α -methyl ether was also obtained from *M. longiflora*.

—G. F. M.

PATENT.

Water-soluble dyes; Production of —. A. M. Hart. E.P. 144,336, 13.12.18.

WATER-SOLUBLE dyes are obtained from animal or vegetable dye-yielding materials, e.g., cochineal, turmeric, madder, etc., by extracting with a solvent, concentrating the solution, and heating this with a water-soluble metallic salt, e.g., alum, copper sulphate, potassium ferrieyanide, etc.

—A. J. H.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cotton; Prolonged action of a moderate heat on bleached — and some other substances. E. Knecht. J. Soc. Dyers and Col., 1920, 36, 195—198.

ALL the materials tested were exposed at 93° C. Bleached cotton yarn and bleached calico, on clock glasses, remained unchanged for the first few days and then turned greyish brown, with formation of oxycellulose. At the end of 336 hrs. the cotton yarn had decreased in strength 33%. When exposed in sealed tubes, yarn decomposed slightly and lost 50% of its strength, and had a remarkable shrivelled appearance. Other cellulose materials, as bleached linen and viscose silk, wood and filter paper, gave similar results. With scoured flannel and spun silk browning occurred after 24 hrs.—A. J. H.

Korean hemp and ramie; Proximate compositions of —. Y. Uyeda. J. Ind. Eng. Chem., 1920, 12, 573—576.

KOREAN hemp and ramie respectively gave the following results:—Loss on drying, 8.83, 10.50; benzene extract, 1.92, 0.86; alcohol extract, 1.20, 0.75; water-soluble substances, 4.50, 3.79; sol. in 1% NaOH, 18.53, 17.27; cellulose, 62.42, 65.88; and lignin, 3.32, 0.66%. Determination of lignin in hemp and ramie affords an indication of the completeness of the retting process. Lignin is partly attacked by alkali digestion. In the case of these fibres the lignin was thus reduced to 1.99 and 0.18% respectively.—C. A. M.

Balloon fabrics; Permeability of — to hydrogen and to helium. R. T. Elworthy and V. F. Murray. Trans. Roy. Soc. Canada, 1919, 13, [iii.], 37—45.

WITH rubbered fabrics the permeability to helium is less than to hydrogen, the ratio of helium to hydrogen being 0.66 by the interferometer method and 0.72 by the catharometer method. With skin-lined fabrics the ratio of helium to hydrogen permeability was found to be almost unity.—J. R. P.

Cellulose; Viscosity of solutions of —. W. H. Gibson, L. Spencer, and R. McCall. Chem. Soc. Trans., 1920, 117, 479—493.

THE viscosity of cuprammonium solutions of purified cotton can be controlled by controlling the conditions of the boiling process with sodium hydroxide. Using 2% caustic soda solution, the viscosity is approximately 50% higher than with 4% solution, but temperature is by far the most important factor in reducing the viscosity. Further, products of different viscosity are obtained from different classes of cotton waste under similar conditions of purification; for example, eastern cottons give products the viscosity of which is about half that of American cotton of similar grade. A close relationship exists between the viscosity of cellulose solutions and solutions of the nitrocellulose derived therefrom. The viscosity determinations were made with a hydrogen capillary viscosimeter and with the falling-sphere viscosimeter (see page 558 A), special precautions being taken in dissolving the cotton and filling the viscosimeter tube to prevent exposure to air or light, which causes progressive changes in the viscosity of the solutions. Variations in copper and ammonia content of the cuprammonium solution prepared by Ost's method (J., 1911, 1247) considerably influenced the viscosity of the cellulose solution. Copper hydroxide prepared by Dawson's method (Chem. Soc. Trans., 1909, 95, 370) showed a fairly definite solubility in ammonia, and an unsaturated solution of this form of the substance, containing 11 g. Cu and 200—210 g. NH_3 per l., was chosen as the standard cuprammonium solution.—G. F. M.

Pyroxylin solutions; Measurement of viscosity of —. E. F. Higgins and E. C. Pitman. J. Ind. Eng. Chem., 1920, 12, 587—591.

EFFLUX viscosimeters with small orifices are suitable for determining the viscosity of pyroxylin solutions of low viscosity, but the steel ball viscosimeter is only suitable for solutions of very high viscosity. The Stormer viscosimeter (in which the viscosity is determined by the speed of a revolving cylinder) is the most generally applicable, since it is unaffected by the density of the solution. (Cf. J.C.S., Aug.).—C. A. M.

PATENTS.

Textile fibrous material; Production of —. M. Hofsté. E.P. 136,804, 5.11.19. Conv., 17.12.18.

FIBROUS material (e.g., ramie) is treated with a concentrated alkaline solution (20—40%), boiled in

a saturated solution of an ammonium salt until the ammonia is completely expelled, washed, and dried. The liberation of gaseous ammonia effects the separation of the fibres.—A. J. H.

Vegetable fibres; Treatment of —. Gillet et Fils, Assees. of C. Schwartz. E.P. 144,563, 12.12.19. Conv., 12.6.19. Addn. to 136,568 (J., 1920, 513 A).

TEXTILE materials coated with a nitrated cellulose solution are washed with dilute solutions of acids, bases, or salts, instead of with pure water, in order to obtain a more rapid and complete precipitation of the nitrocellulose.—A. J. H.

Cellulose esters; Manufacture of dissolved or gelatinised —. G. Bonwitt. E.P. 138,078, 17.1.20. Conv., 6.6.17.

CELLULOSE esters, e.g., acetyl-, nitro-, nitroacetyl-cellulose, are dissolved or gelatinised by furfural or a homologue.—A. J. H.

Cellulose ester [acetate] composition, and method of making the same. Cellulose-nitrate composition. Cellulose-acetate composition. P. C. Seel, Assr. to Eastman Kodak Co. U.S.P. (A) 1,342,601, (B) 1,342,602, and (C) 1,342,603, 8.6.20. Appl., (A) (B) 7.2.18; (C) 26.4.19.

(A) A composition comprising cellulose acetate and a chloro substitution product of naphthalene. (B) A transparent flexible film consists of cellulose nitrate, camphor, and an amount of the chlorine derivatives of the cyclic hydrocarbons $\text{C}_{2n}\text{H}_{n+2}$ and their homologues, greater than half the weight of camphor. (C) A composition comprising cellulose acetate and ethyl propionate.—A. J. H.

Acetylcellulose composition, and method of making same. J. G. Jarvis. U.S.P. 1,313,135, 8.6.20. Appl., 13.3.19.

THE composition consists of 75 pts. of cellulose acetate, 25 pts. of naphthalene, and 60 pts. of acetone.—A. J. H.

Sulphite and like digesters; Methods of heating —. J. K. Ruths, and Aktiebolaget Vapora-kumulator. E.P. 144,084, 29.5.19. (Cf. U.S.P. 1,292,080; J., 1919, 283 A.)

THE period of digestion is shortened without affecting the quality of the product if steam of low pressure, obtained from an accumulator connected with the sulphite-boiler, be used for the steaming operation, and also for starting the digestion which is then completed with steam of a higher pressure.—A. J. H.

Soda-cellulose manufacture; Elimination of malodorous substances from the waste gases from —. C. G. Schwalbe. G.P. 319,594, 31.7.17.

THE gases are brought into contact with finely-divided wood, sawdust, or other vegetable waste product. Mercaptans etc. may be destroyed before this treatment by mixing the gases with an oxidising gas, such as chlorine, ozone, etc., or the wood or the like may be subsequently treated with an oxidising gas or liquid.—C. A. M.

Paper-making machines. Great Northern Paper Co., Assees. of C. E. Pope. E.P. 137,061, 24.12.19. Conv., 31.1.17.

Paper-making machine. A. J. Haug, Assr. to Improved Paper Machinery Co. U.S.P. 1,313,505, 15.6.20. Appl., 5.2.17.

Pulp digestion; Manufacture of caustic soda, more particularly from residues recovered from the alkali used in — and containing sodium carbonate. Dorr Co., Assees. of D. S. McAfee. E.P. 131,272, 31.3.19. Conv., 16.8.18.

See U.S.P. 1,308,184 of 1919; J., 1919, 630 A.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Dyeing machine. H. M. Dudley. U.S.P. 1,342,711, 8.6.20. Appl., 21.9.17.

A RECEPTACLE contains a series of fibre chambers having non-perforated sides and perforated top and bottom plates, the top plates being movable relatively to the bottom plates. The fibre chambers are arranged between two perforated plates spaced from the top and bottom plates respectively, and means are provided for forcing a liquid in either direction through the device.—A. J. H.

Dyeing machine. W. J. Going, Assr. to The Klaunder-Weldon Dyeing Machine Co. U.S.P. 1,343,260, 15.6.20. Appl., 8.5.16.

THE machine consists of a vat containing a removable framework which supports a number of removable yarn sticks and dye liquor deflectors.—A. J. H.

Hosiery dyeing machine. H. M. Dudley. U.S.P. (A) 1,344,120 and (B) 1,344,121, 22.6.20. Appl., 5.6.18.

THE fibre chambers are formed by perforated plates fixed lengthwise between two end plates attached to a perforated, hollow, rotary cylinder so as to form a reel. In (A) means are provided for continuously forcing a liquid through the machine.—A. J. H.

Fibre-treating machine. H. M. Dudley. U.S.P. 1,344,122, 22.6.20. Appl., 3.12.18.

A DYEING machine contains a series of fibre chambers each comprising two perforated plates, between which are a series of hollow cylinders. Means are provided for forcing a liquid through the fibres compressed between the plates.—A. J. H.

Cotton yarn or cloth; Process for treating [improving the lustre and texture of] — S. Kashitani. E.P. 144,083, 28.5.19.

COTTON yarn or fabric is treated for 1–50 min. in sulphuric acid of 52°–60° B. (sp. gr. 1.56–1.71), washed in water under vibration to remove loose fibres, immersed for 10–15 min. in a solution of caustic soda of 8°–15° B. (sp. gr. 1.06–1.12) to improve the lustre, neutralise the free acid, and maintain the colour, then treated with a 3% solution of borax to render it non-combustible and neutral. The fabric may be further softened by treatment with a 5% solution of glycerin, or with calcium chloride, glucose, or soap solution.—A. J. H.

Vegetable fibres; Process for the treatment of — Gillet et Fils., Asses. of C. Schwartz. E.P. 144,204, 12.12.19. Conv., 23.7.19. (Of. E.P. 136,568; J., 1920, 513 A).

CELLULOSE fibres coated with nitrated starch compounds have wool-like properties, are strong and soft, and dye directly with basic dyes. The fabric is treated for several minutes at –5° to 20° C. with a solution of starch in 65% nitric acid, then preferably treated with a solution of any suitable salt to aid the precipitation of the nitrated amylaceous substance, and afterwards washed. Alternatively the fabric may be first dressed with a starch paste, dried, treated with 65% nitric acid, the excess acid expressed, and washed. Print effects may be produced with the nitrated starch.—A. J. H.

Mercerisation [of cotton and artificial silk union fabrics]. S. M. Jones, Assr. to Arnold Print Works. U.S.P. (A) 1,343,138 and (B) 1,343,139, 8.6.20. Appl., 28.11.19.

COTTON union fabrics containing viscose silk are

mercerised without injury to the latter by a solution of caustic soda containing (A) formaldehyde or (B) phenol.—A. J. H.

Skein-mercerising machines; Means for electrically controlling — J. E. Wild and W. W. Caldwell, Assrs. to American Thread Co. U.S.P. 1,343,804, 15.6.20. Appl., 17.10.18.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Arsenic-free sulphuric acid. K. Scheringa. Pharm. Weekblad, 1920, 57, 421–422.

THE acid is heated to fuming with the addition of a small quantity of a sulphite. After dilution with an equal bulk of water, it is electrolysed for at least one day, and may then be used for analytical purposes after concentration.—W. S. M.

Reactions started by a primer. E. Berger. Comptes rend., 1920, 170, 1492–1494.

A NEW priming mixture consisting of 60% of sodium or potassium nitrate and 40% of commercial calcium silicide is suggested for starting such reactions as those of the thermit type. The mixture may even be mixed with gum arabic and applied to paper, such paper after drying being a useful form in which to light the mixture. This primer may be lit with a match and burns with a very high-temperature flame. It has been used successfully to start such reactions as the reduction of boron phosphate and arsenate by aluminium, the reduction of calcium and barium sulphates by red phosphorus, the preparation of silicon and boron fluorides from lead fluoride, and the reduction of sulphates by calcium silicide.—W. G.

Chlorides; Production of — by primed reactions. E. Berger. Comptes rend., 1920, 171, 29–32. (Of. ante.)

ALUMINIUM reacts spontaneously or by preliminary priming on a number of chlorides of metals and metalloids; in some cases magnesium is still more active. In a similar manner a considerable number of metals will act on organic chlorides such as carbon tetrachloride, tetra- and hexachloro-ethane, etc., to give the corresponding metallic chlorides which may be vaporised owing to the heat generated by the reaction when once started. Liquid organic chlorides may be first absorbed in kieselguhr or sawdust. Such mixtures, zinc being the metal used, found application in the war for the production of smoke clouds. Later, owing to the lack of organic chlorides, zinc chloride alone was used, being vaporised by means of a mixture of sodium nitrate and calcium silicide.—W. G.

Double salts; Application of a new physico-chemical method of analysis to the study of — R. Dubrisay. Comptes rend., 1920, 170, 1582–1584.

IF a mixture of solutions of sodium and potassium sulphates is mixed with phenol, the temperature of mixing observed agrees closely with that calculated additively from the temperature of mixing of the individual solutions with phenol. Where a mixture of solutions of potassium and zinc sulphates is mixed with phenol there is a difference between the observed and calculated temperatures of mixing varying with the proportions of the two salts present. It is a maximum when the salts are present in equimolecular proportions and indicates the presence, in solution, of a double salt.—W. G.

Chromium sulphate; Constitution of the lilac grey complex — A. Recoura. Comptes rend., 1920, 170, 1494–1497.

THE lilac grey chromium sulphate previously

described (*cf.* J., 1920, 107 A) is shown to consist when freshly prepared of 1 mol. of the green sulphate in its depolymerised state and 2 mols. of the violet sulphate. On standing the green sulphate rapidly and spontaneously polymerises and then masks the sulphate ions of the violet salt. (*Cf.* J.C.S., Aug.)—W. G.

Mercuric salts; Precipitation of — by hydrogen sulphide. P. Jolibois and P. Bouvier. *Comptes rend.*, 1920, 170, 1497—1498.

THE black precipitate obtained with excess of hydrogen sulphide and a dilute solution of mercuric chloride has the composition HgS , the white precipitate obtained when there is excess of mercuric chloride having the composition $2\text{HgS}, \text{HgCl}_2$. There is no indication of the existence of any other intermediate compound.—W. G.

Fluorite; Colouring matters of red and blue —. C. S. Garnett. *Chem. Soc. Trans.*, 1920, 117, 620—622. (*Cf.* J., 1919, 628 A.)

THE colour of "Blue John" appears to be due to films of organic colouring matter lying parallel to and in the plane of the faces of the otherwise colourless crystal and also at the crystalline junctions, and probably deposited on the surfaces of the crystals at intervals during their growth. A very intensely coloured specimen contained 0.27% of carbon, and on distillation gave off inflammable vapours, and a yellowish-brown oil collected in the condenser. The residual fluorite was colourless. The colour of red fluorite, on the other hand, is not destroyed by heat, but is readily extracted from the powdered material by boiling hydrochloric or nitric acid. The solution contained rare earths, and nothing but insignificant quantities of other elements.—G. F. M.

Tartaric acid compounds of antimony. A. Blanchetière. *Bull. Soc. Chim.*, 1920, 27, 477—490.

A STUDY of the solution of antimony hydroxide in a solution of tartaric acid confirms Jungfleisch's view that the process is one of esterification. The monostibiotartaric acid is best obtained by extraction of complexes, richer in tartaric acid, with acetone. (*Cf.* J.C.S., Aug.)—W. G.

Hydrogen peroxide; Catalytic decomposition of — by colloidal platinum. A. de G. Rocasolano. *Comptes rend.*, 1920, 170, 1502—1504.

USING electrosols of platinum, it is shown that the decomposition of hydrogen peroxide by colloidal platinum is not a unimolecular reaction. During the reaction the catalyst itself apparently undergoes some change. The altered catalyst can decompose further amounts of the peroxide, and the reaction is then unimolecular.—W. G.

Gas adsorption [by charcoal]; Effect of pressure on —. A. Pickles. *Chem. News*, 1920, 121, 1—2.

SIX kinds of charcoal, previously heated, were saturated with dry ammonia, and placed successively in a vessel, immersed in cold water, and connected with a manometer and water pump. In all cases the pressure at first increased and ultimately decreased. The denser charcoals, notably those from palm nut, coconut, and fruit stones, were the most efficient gas adsorbents. Iodine liberated by chlorine water from iodine residues was removed by warming the solution with charcoal dust, but only 17% I could be adsorbed from a solution of iodine in benzene. About 80% of benzoic acid was adsorbed from a solution in benzene. The most efficient decoloriser was birch charcoal dust.

—C. A. M.

Adsorption of gases by carbonised lignite. S. McLean. *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 187—199.

THE adsorption of air, carbon dioxide, oxygen,

hydrogen, and nitrogen by carbonised lignite was studied. Oxygen is adsorbed much more readily than nitrogen. The presence of water vapour decreases the amount of gas adsorbed. No adsorption is permanent, since there are but few cases where the last weight is greater than the first, and these may be due to experimental errors. The fact that with oxygen in most cases the last weight is less than the first indicates that the oxygen combines with the lignite forming carbon dioxide, which is given off when the lignite is heated.—J. R. P.

Helium and hydrogen in air; Use of the Jamin interferometer for the estimation of small amounts of —. J. C. McLennan and R. T. Elworthy. *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 19—25.

TWO methods of calibrating the Jamin interferometer for the determination of small amounts of helium and hydrogen in air are outlined, one based on the relation between the difference of path caused by the displacement of air in one tube by the mixture and the resulting shift of bands, and the second based on the change of refractive index of air in one tube caused by lowering the pressure of the air. The accuracy was $\pm 0.5\%$. With longer tubes a greater accuracy could be obtained.—J. R. P.

Helium content of mixtures of gases; Estimation of the — by the use of a catharometer. V. F. Murray. *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 27—35.

THE Shakespear "hydrogen purity meter," high and low percentage "hydrogen explorers," and a Shakespear "permeameter explorer" have been calibrated for use with helium.—J. R. P.

Helium mixtures; Continuous flow apparatus for the purification of impure —. E. Edwards and R. T. Elworthy. *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 47—52.

HELIUM containing at least 12% of impurity can readily be purified by passing in a continuous stream over charcoal at the temperature of liquid air or oxygen. The helium is not absorbed. The rate of flow can be increased to at least 10 l. per hr. without decreasing the efficiency of the absorption. The maximum possible rate of flow was not determined. By the use of two or more sets of charcoal tubes in parallel the process may be made continuous, as the charcoal may be revived without disturbing the flow.—J. R. P.

Hydrogen and helium; Combustibility of mixtures of —. J. Satterly and E. F. Burton. *Trans. Roy. Soc. Canada*, 1919, 13, [iii.], 211—215.

THE combustibility was tested by a lighted match and by a white-hot platinum spiral. Under the conditions of experiment the percentage of hydrogen could be raised to 26 before the mixture became inflammable; if the percentage exceeded 28 the mixture would burn.—J. R. P.

Carbonic oxide; Process and apparatus for treating gases containing — [in connexion with synthesis of ammonia]. General Chemical Co., Assees. of F. W. de Jahn. E. P. 124,760, 28.2.18. Conv., 3.11.17.

GASES consisting of 1 vol. of nitrogen and 3 vols. of a mixture of carbon monoxide and hydrogen, produced by passing the requisite quantities of

steam and nitrogen over red-hot carbonaceous material, are mixed with regulated quantities of steam, and the mixture is passed through a layer of iron oxide maintained at 550° C., whereby the carbon monoxide is catalytically oxidised to carbon dioxide with the liberation of an equal volume of hydrogen. After absorbing the carbon dioxide, the resulting mixture of nitrogen and hydrogen is used for the production of ammonia. The oxidation of the carbon monoxide is carried out in a specially constructed cast-iron chamber supported on three legs, which are so arranged on supports that they are capable of movement to allow for expansion when the chamber is heated. The gases are preheated before entering the reaction chamber by means of the flame from a producer-gas burner, and the heat of the issuing gases is used to preheat a further quantity of the original mixture.—A. R. P.

Alkali alumino-silicates; Decomposition of —. E. Bergve. E.P. 127,586, 9.5.19. Conv., 27.5.18.

NATURAL alkali alumino-silicates are heated to 800°–1200° C., without melting, and sulphur vapour is passed through the mass to produce "oxy-sulphosilicates" of the alkalis and aluminium. The mass is extracted with water in an autoclave, whereby hydrogen sulphide is evolved and soluble alkali sulpho-aluminate is formed, from which aluminium hydroxide may be recovered.—A. R. P.

Copper sulphate; Obtainment of — from ores containing copper. J. S. Ross. E.P. 143,973, 6.3.19.

COPPER carbonate ores are leached with an excess of 5% sulphuric acid, air, with or without superheated steam, being forced through the charge until the copper is dissolved. The liquor is drained off on to a fresh charge of ore and allowed to remain in contact therewith until it becomes basic, when it is again drawn off and concentrated to 52° Tw. (sp. gr. 1.26) after the addition of copper oxide or other basic substance. Air, with or without superheated steam, is forced through the liquid in minute jets, and the whole allowed to cool. After filtration the clear solution is used for the production of pure copper or copper sulphate crystals. The second charge of ore is used as the first charge in the next cycle of operations.—A. R. P.

Rock salt; Purifying —. L. W. Damman. E.P. 144,022, 16.9.19.

Rock salt is ground to grains of about 1 mm. size, and the finer, less pure material separated by sifting. The coarser material is further purified by a suitable grading operation, e.g., by a jiggling process in saturated brine, whereby the heavier impurities fall to the bottom, whilst the lighter particles of purified salt are collected separately, and, after drying, are suitable for table use.

—A. R. P.

Evaporating plant for the manufacture of salt from brine or other like purposes. M. Allen. E.P. 144,023, 9.4.19.

THE brine circulation in a series of open pans is accelerated by forcing the liquid by means of a steam pump, or the like, into a system of flow and return pipes arranged to pass through the flues or furnaces of each of the pans. The brine is discharged into a settling tank, which it enters and leaves at the top, thus allowing any solid impurities to settle. A by-pass is provided to the tank and to each of the evaporating pans, so as to cut any desired unit out of the circuit when required.

—A. R. P.

Salt; Method of, and apparatus for producing purified —. F. G. Wheeler, Assr. to Bleach Process Co. U.S.P. 1,342,519, 8.6.20. Appl., 16.11.18.

A SALT is separated from a solution containing other salts by passing the solution through an open

atmospheric cooler, whereby crystals of the required salt are deposited on the cool surface. Means are provided for removing the crystals from the cooler, and a centrifugal machine for separating them from the solution.—A. R. P.

Ammonium sulphate; Manufacture of —. S. M. Shadbolt and J. E. Grainger. E.P. 144,030, 16.4.19.

THE crystals of ammonium sulphate and mother liquor in the liquor pit are lifted by means of ammonia vapours mixed with steam to a neutralising chamber fitted with baffle plates over which the liquid flows while ammonia vapours are passed through the chamber, the excess of ammonia being returned to the saturator.—A. R. P.

Purifying [burner] gases and producing briquetting material. T. L. Briggs, Assr. to General Chemical Co. U.S.P. 1,301,372 and 1,301,373, 22.4.19. Appl., 1.6.16 and 15.5.17.

GASES derived from the burning of sulphur ore and containing sulphur dioxide, oxygen, nitrogen, and small quantities of sulphur trioxide and iron oxide dust, are filtered through a layer of the burnt ore, which is pulverised to such a size that it will pass through a sieve of 1 in. mesh, but not through a sieve of 0.25 in. mesh. The gases are passed horizontally through a vertical layer of the ore at a temperature of 900° F. (480° C.). The filtering layer is preferably about 18 in. thick, and the lower layer is periodically removed by vibration through a grate and the upper layer simultaneously replenished with fresh material. The material is contained between a pair of vertical screens, one of which is adjustable to and from the other to vary the thickness of the filtering layer.—W. F. F.

Fixing nitrogen; Process for —. C. T. Thorssell and H. L. R. Lundén, Assrs. to Aktiebolaget Kvaefveindustri. U.S.P. 1,342,834, 8.6.20. Appl., 9.7.19.

IN the production of cyanides by the interaction of nitrogen with a heated mixture of carbonaceous material and alkaline compounds in the presence of finely-divided metal, the latter is prepared by reducing compounds containing no other elements than the metal, hydrogen, oxygen, carbon, and nitrogen at a temperature below 550° C., and is immediately introduced into the reaction zone.

—J. S. G. T.

Ammonium perchlorate; Manufacture of — from sodium perchlorate and ammonium sulphate. G. C. Given, H. G. Quaid, and R. A. Long, Assrs. to Atlas Powder Co. U.S.P. 1,342,956, 8.6.20. Appl., 23.10.18.

TO a nucleus solution of sodium sulphate and ammonium and sodium perchlorates are added sodium perchlorate and ammonium sulphate. Anhydrous sodium sulphate separates and is removed, and ammonium perchlorate is then separated below 22° C.—A. E. D.

Manganese peroxide; Process of forming —. H. C. Chapman, Assr. to National Carbon Co. U.S.P. 1,343,390, 15.6.20. Appl., 29.6.17.

MANGANESE peroxide for use as a battery depolariser is prepared by mixing manganese carbonate with a salt containing chlorine and roasting the mixture.—W. J. W.

Brines; Process for separation of constituents of —. Process for separating compounds from brines. H. W. Morse, Assr. to American Trona Corp. U.S.P. (A) 1,343,400 and (B) 1,343,401, 15.6.20. Appl., 7.11 and 26.11.18.

(A) BRINE is evaporated to such a degree that on further heating the precipitated salts with the

liquor to 90°–100° C., potassium chloride and borax will redissolve, after which these salts are separated from solution by crystallisation. (u) The solution of potassium chloride and borax may be subjected to a rapid cooling in order to separate potassium chloride alone.—W. J. W.

Potassium salts; Process for recovery or purification of —. W. Hirschkind, Assr. to California Alkali Co. U.S.P. 1,313,508, 15.6.20. Appl., 8.4.18.

POTASSIUM salts are recovered from mixtures containing boric acid by extracting the latter with alcohol.—W. J. W.

Aluminium chloride; Process for producing anhydrous —. P. Danckwardt. U.S.P. 1,343,662, 15.6.20. Appl., 23.6.19.

A METAL chloride is electrolysed under such conditions that the nascent chlorine formed at the anode reacts with an aluminium compound, thereby producing aluminium chloride which volatilises and is condensed in suitable chambers.—A. R. P.

Chrome alum; Process for manufacturing —. G. H. Hultman. U.S.P. 1,343,725, 15.6.20. Appl., 11.11.19.

FERROCHROME is dissolved in sulphuric acid, and a soluble potassium salt is added to the solution. —W. J. W.

VIII.—GLASS ; CERAMICS.

Glass furnace refractories; Preservation of — by water-cooling. E. B. Christmas. J. Soc. Glass Tech., 1920, 4, 128—138.

By adapting water-cooling devices to glass-furnaces, the durability of the refractory materials and the efficiency of the workmen may be greatly increased without introducing any radical changes into works practice. The water-cooling devices should be made of thin, welded steel plates (castings are unsuitable), and the effluent water should have a temperature of 180° F. (82° C.) or 5°–10° C. below the temperature at which precipitation of any saline matter in the water can occur.—A. B. S.

Glass; Development of various types of —. C. J. Peddle. J. Soc. Glass Tech., 1920, 4, 3—107.

LIME-SODA glasses of the types $100\text{SiO}_2, 40\text{Na}_2\text{O}, x\text{CaO}$ and $100\text{SiO}_2, 20\text{Na}_2\text{O}, x\text{CaO}$, in which x lies between 5 and 40, can be made at temperatures above 1300° C. They all attack the melting pot in proportion to the soda or lime, or both, present. The density, refractive index, and total dispersion rise on increasing either the lime or soda present, the lime having the greater effect. Lime-soda glasses containing more than 72% SiO_2 tend to devitrify, silica being separated. Glasses containing more than 10% CaO and more than 20% Na_2O devitrify readily, but with less than 15% Na_2O , up to 15% CaO may be present without devitrification. With more than 15% Na_2O the glasses become dim on exposure. All the lime-soda glasses in the first series weather too badly to be used as optical glasses, and all in the second series, except $100\text{SiO}_2, 20\text{Na}_2\text{O}, 20\text{CaO}$, are useless, as they devitrify too readily. Glasses of the latter type are not sufficiently durable for first-class optical glass, but are useful for jars, bottles, etc. In modern glass manufacture the tendency is to use mixtures too high in silica and soda and too low in lime. After continued use of cullet from which some alkali has been volatilised the glass works badly. Instead of the customary addition of soda—which gives a glass lacking durability—it is better to add lime so as to bring the composition of the glass up to $100\text{SiO}_2, 20\text{Na}_2\text{O}, 20\text{CaO}$. Lime-potash glasses corresponding to the formulae $100\text{SiO}_2, 40\text{K}_2\text{O}, x\text{CaO}$ and $100\text{SiO}_2, 20\text{K}_2\text{O}, x\text{CaO}$, where x lies between 5 and 40, are more brilliant, more brittle, and less coloured than the corresponding lime-soda glasses. They had to be founded above 1300° C., and attacked the melting pot. Their total dispersion, refractive index, and density increase irregularly with the lime and potash content, the lime having the greater effect on density, and the potash on the refractive index and total dispersion. Lime-potash glasses containing more than 34% K_2O devitrify readily. The solubility decreases as the lime and silica content rises and increases rapidly as the potash increases. The durability is increased by high lime and silica, and diminished by high potash. Soda-lime glasses devitrify more easily than potash-lime glasses, but a high lime content reduces devitrification. Soda-lime glasses are more soluble than the corresponding potash-lime glasses, and glasses containing equal weights of soda and potash are less soluble than either the corresponding soda-lime or soda-potash glasses. Weight for weight soda is a better flux than potash, and a soda glass is more fusible than the corresponding potash glass. Molecule for molecule, soda is more powerful than potash in inducing devitrification. The lime-potash glasses are not sufficiently durable for optical purposes. Lime-soda-potash glasses corresponding to $100\text{SiO}_2, 20\text{Na}_2\text{O}, 20\text{K}_2\text{O}, x\text{CaO}$ and $100\text{SiO}_2, 10\text{Na}_2\text{O}, 10\text{K}_2\text{O}, x\text{CaO}$ are not of first-class durability for optical instruments, though glasses corresponding to $100\text{SiO}_2, 10\text{Na}_2\text{O}, 10\text{K}_2\text{O}, 20\text{CaO}$ have a durability equivalent to Schott and Genossen's No. 0337 silicate crown glass. The refractive index and density of these glasses increase irregularly with an increase in either lime or alkali, and in these and other properties the glasses are intermediate between the lime-soda and lime-potash glasses. The best glasses in all the foregoing series can be represented by the simple formula $5\text{SiO}_2, 1\text{R}_2\text{O}, 1\text{CaO}$; glasses corresponding to the usual Benrath formula $6\text{SiO}_2, \text{R}'_2\text{O}, \text{R}''\text{O}$ are rather more difficult to melt, more durable, but devitrify more easily.—A. B. S.

Weathering of glass; Mechanics of —. F. R. von Richowsky, J. Amer. Ceram. Soc., 1920, 3, 309—312.

THE mechanism of weathering consists in the ad-

sorption or absorption of water in the following successive stages: true surface adsorption; solution of the adsorbed molecules in the glass; reaction of the dissolved water with the glass, forming a surface film; absorption of water by this film, and further reactions; extraction of soluble salts from the film; and solution of the silica skeleton film.—A. B. S.

Optical glass; Practical test for resistance of — to weathering. F. R. von Biehowsky. J. Amer. Ceram. Soc., 1920, 3, 296—308.

THE sample, in the form of half-inch cubes, is heated with a 5% solution of sodium hydroxide in a steel bomb at 225° C. for 2 hrs., or with hydrochloric acid (1: 1) in a sealed tube of Jena combustion glass at 175° C. for 6 hrs. The appearance of the glass and the loss in weight are noted. The results obtained by the two tests do not always place a series of glasses in the same order of stability.

—A. B. S.

Lead glass for table ware; Comparative effects of soda and potash on —. F. W. Hodkin and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 120—125.

ON comparing lead-soda, lead-potash, and lead-soda-potash glasses, it was found that lead-soda glasses are the most fusible and lead-potash glasses the least fusible, but the most viscous, and that a lead-soda-potash glass containing soda and potash in equivalent proportions fuses more readily and is more durable than either a lead-soda or a lead-potash glass. The presence of 2 pts. of borax per 100 pts. of sand increases the durability of these glasses.—A. B. S.

Lime-soda glasses; Optical properties of some —. J. R. Clarke and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 111—115.

THE refractive indices and dispersions for the C, D, F, and G lines, the value of v , and the limit of transmission of ultra-violet light in a series of glasses corresponding to $2\text{Na}_2\text{O} \cdot 0.6\text{SiO}_2$ to $\text{Na}_2\text{O} \cdot \text{CaO} \cdot 0.6\text{SiO}_2$ were determined. The refractive index for the D line is an additive property, the relation between refractive index and composition being linear, and all the refractive indices increase regularly as soda is replaced by lime. The total and partial dispersions and values of v were practically constant (about 59) in the glasses examined. The ultra-violet absorption band remains fairly constant at 2950 Å.U., the glasses being very transparent to ultra-violet light.—A. B. S.

Soda-lime glasses; Density of —. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 126—128.

THE substitution of lime for soda increases the density of a glass, this property being additive. Winkelmann and Schott's factors of 2.3 for the density of SiO_2 , 2.6 for Na_2O , and 3.3 for CaO in a glass give low results and require revision.

—A. B. S.

Magnesia-containing glasses; Thermal expansion of —. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 115—120.

WHEN magnesia replaces soda in a soda-magnesia glass, there is a great reduction in the thermal expansion. The thermal expansion appears to be an additive property relative to the composition of a glass. Assuming that the coefficient of linear expansion of fused silica is the same as that of silica in combination in glass, the linear expansion factors of various oxides in glasses are calculated as: SiO_2 0.05, Na_2O 4.32, CaO 1.63, MgO 0.45. Tabulated results for a series of lime glasses and magnesia glasses show that the observed expansions agree better with the expansions calculated with

the aid of the authors' factors than with those calculated by means of Schott's factors.—A. B. S.

Casting slip; Effect of the method of preparation on the viscosity of a —. V. S. Schory. J. Amer. Ceram. Soc., 1920, 3, 286—295.

THE viscosity of a casting slip may be varied by altering the percentage of alkaline reagent and of water and also by varying the mode of preparation of the slip. Slips with high viscosity were obtained by first adding the water to the blunger, then the sodium carbonate and silicate together, and then the clay. Slips of low viscosity were obtained by adding the sodium carbonate before the clay, and the sodium silicate last. When filter-press cakes are ground with water and alkaline reagents, slips of low viscosity are produced by the use of wet cakes, or if the sodium carbonate is added prior to the sodium silicate. Grinding produces slips of a higher viscosity than blunging. The firmest products were obtained by blunging, using the lowest practicable proportion of alkaline reagents.

—A. B. S.

Terra cotta; Satisfactory method of using barium hydroxide in —. M. E. Gates. J. Amer. Ceram. Soc., 1920, 3, 313—315.

A SOLUTION of barium hydroxide is preferable to barium carbonate as an anti-scum reagent on terra cotta bodies. The solution is supplied from a tank provided with a mechanical stirrer, through a siphon, the end of the shorter arm of which is attached to a float. The rate of delivery is varied by altering the length of the longer leg of the siphon.—A. B. S.

Titanium enamels. R. D. Landrum and L. J. Frost. J. Amer. Ceram. Soc., 1920, 3, 316—321.

TITANIUM oxide (rutile) is an opacifying agent, but an excess prevents the enamel remaining properly in suspension. Boric oxide appears to be a desirable constituent of titanium enamels. Titanium oxide is harmful in a ground coat, destroying the cobalt blue, and lowering the melting point and the adhesion of the enamel. Three good titanium enamels had the following formulae: (0.742 Na_2O , 0.078 K_2O , 0.180 CaO) 0.3 Al_2O_3 , (2.444 SiO_2 , 0.371 TiO_2 , 0.768 F_2); (0.672 Na_2O , 0.142 K_2O , 0.186 CaO) 0.31 Al_2O_3 , (2.521 SiO_2 , 0.398 TiO_2 , 0.794 F_2); (0.536 Na_2O , 0.146 K_2O , 0.318 CaO) 0.332 Al_2O_3 , (2.710 SiO_2 , 0.152 B_2O_3 , 0.270 TiO_2 , 1.067 F_2).—A. B. S.

PATENTS.

Printing surfaces. D. Motta, E. Rugiu, and A. Villain. E.P. 143,943, 2.1.19.

PLATES for printing are made of sheets of paper covered with a composition consisting of equal parts of calcium carbonate and magnesium silicate, with an organic agglutinant such as gum. The surface may be provided with a network or grain in relief to facilitate engraving and may afterwards be rendered insoluble by means of formalin.—A. B. S.

Porous refractory materials; Manufacture of —. L. Denis. E.P. 144,359, 5.3.19.

A POROUS refractory material suitable for surface combustion is obtained by calcining a mixture of 30 pts. of "rich refractory earth" containing 70—80% of sand with 30 pts. of magnesia, 25 pts. of "poor light earth" containing more than 80% of sand, and 5 pts. of sawdust. The mixture is heated to at least the temperature at which it will be used.

—A. B. S.

Kiln. C. H. Zwerman. U.S.P. 1,308,973, 8.7.19. Appl., 27.3.19.

Two tunnel kilns are arranged side by side with a common dividing wall, and each comprises a "water-smoking" zone, preheating zone, firing

zone, and cooling zone. The cooling and firing zones of one kiln are opposite the "water-smoking" and preheating zones of the other respectively. A number of burners supplied with producer gas deliver hot gas into the top of the firing zone, and the gases are discharged at the bottom into flues from which they pass into flues around the preheating zone of the kiln. The air in the "water-smoking" zone of one kiln is heated by passing it through flues adjacent to the cooling zone of the other kiln. Overheating of the materials treated and the roof of the tunnel is prevented by providing passages in the roof through which air is passed to preheat it on its way to the burners. This air enters horizontal flues below the kilns at their mid-points and passes in both directions to vertical flues at both ends of the kiln, through which it passes upwards to the flues in the roof. —W. F. F.

Glass; Apparatus for feeding or delivering molten material, such as —, in separate lumps or charges. W. L. Pratt. From C. H. Rankin, C. H. Blumenauer, and C. J. P. Pratt. E.P. 144,552, 6.11.19.

IX.—BUILDING MATERIALS.

Cement; Effect of storage on —. D. A. Abrams. Structural Materials Research Lab., Lewis Institute, Chicago. Bull. 6, June, 1920. 28 pp.

PORTLAND cement was stored for periods up to two years under varying conditions. Compression tests of concrete and mortar showed that the cement deteriorated on storage in cloth sacks, in paper bags, and in sacks covered with Portland cement or hydrated lime. The greater part of the deterioration occurred during the first three months, after which period the cement showed 80% of its original strength, after 6 months 71%, after 1 year 61%, and after 2 years 40%. The 7-day tests showed a greater deterioration than the 28-day and later tests. The strength of concrete is not permanently reduced to that shown by the 7-day and 28-day tests. The storage period is of more importance than the conditions of storage provided direct access of moisture is prevented. Storage of cement prolongs the time of initial and final setting; it affects the normal consistency only slightly. The deterioration appears to be due to the absorption of atmospheric moisture. Cement in temporary storage should be kept not less than 1 ft. above the ground and 1 ft. away from exterior walls. A bibliography on the storage of cement is included. —A. B. S.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast iron; Growth of grey —. M. Okôchi and N. Satô. J. Coll. Eng., Tokyo Imp. Univ., 1920, 10, 53-71.

THERE are two cases of growth in grey cast iron, one occurring at temperatures higher than that of transformation, the other during transformation.

The first case is explained as permanent expansion due to the pressure of occluded gases. The flakes of graphite in the iron absorb a large amount of gas, and the spaces round them are also filled with gas. When the iron is heated to a high temperature the pressure of the occluded gases is greatly increased, and if the high temperature is maintained plastic deformation takes place with corresponding increase in volume. A state of equilibrium is set up between the pressure of the gases and the resistance of the material. Raising the temperature disturbs this equilibrium and causes further deformation, while cooling reduces the gas pressure and causes penetration of gases along the flakes of graphite from the surface of the iron. The second case is also considered to be due to the pressure of occluded gases. The transformation from alpha to gamma iron is accompanied by contraction, which the pressure of the gases resists, so that the time for transformation must be extended. This requires repeated heatings, whereby the quantity of occluded gas is increased and the pressure of the gas gradually overcomes the contraction and produces increase in volume. Prevention of growth may be brought about by decarbonising the surface in order to prevent penetration of gases along the flakes of graphite. —J. W. D.

Carbide carbon in steel; Estimation of —. K. Inouye. J. Coll. Eng., Tokyo Imp. Univ., 1920, 10, 145-151.

Two methods of estimating carbide carbon in steel were investigated, viz., those of Ledebur and of Arnold and Read, and the amount of carbon in this form in steels having various microstructures was determined. The amount of carbide carbon increases with the rate of cooling, and the slower a steel is cooled below the A_1 the greater is the amount. This is indicated in the structure, steels having a sorbitic, pearlitic, and spheroidic structure respectively containing 0.51, 0.71, and 0.80% of carbide carbon. In carefully annealed steels only about 90-92% of the total carbon is recovered in the form of carbide, indicating that a certain amount of hardening carbon remains in solid solution. —J. W. D.

[Steel] guns; Erosion of —. M. Okôchi. J. Coll. Eng., Tokyo Imp. Univ., 1919, 9, 239-265.

THE causes of the erosion of guns are discussed, and additional reasons are given for the lower resistance to erosion of high-carbon steel compared with low-carbon steel and of nickel or nickel-molybdenum steel compared with ordinary gun steel (cf. J., 1919, 143 A). —J. W. D.

Nickel steels; Thermal change of the elastic properties of —. P. Chevenard. Comptes rend., 1920, 170, 1499-1502.

IN reversible nickel steels the coefficient of variation of the modulus of torsion is characterised by a rapid increase to a maximum, which corresponds to the minimum of dilatability, and then a gradual diminution. For irreversible alloys the results do not indicate any anomaly. Tempering and hammer hardening diminish the value of the modulus of torsion, which increases, however, with the temperature of annealing, there being a maximum of rapidity between 450° and 550° C. The thermoelastic coefficient is affected by the treatment which the alloy undergoes, but, contrary to what happens in the case of the dilatability, hammer hardening diminishes the amplitude of the anomaly, whilst tempering increases it. —W. G.

Iron; Corrosion of —. R. Kattwinkel. Z. angew. Chem., 1920, 33, 156.

AN incrustation found in a steam pipe was strongly magnetic and contained 99.1% Fe_3O_4 . —W. P. S.

Phosphorus; Determination of — in tin bronzes. L. Bertiaux. *Ann. Chim. Analyt.*, 1920, 2, 167—168.

FIVE g. of the alloy is dissolved in a mixture of nitric acid (36° B., sp. gr. 1.332), 15 c.c., hydrochloric acid (21.5° B., sp. gr. 1.175), 20 c.c., and water, 35 c.c., the solution boiled to expel nitrous vapours, treated with 25% ammonium chloride solution, 35 c.c., and 10% ammonium acetate solution, 20 c.c., again boiled, and the phosphoric acid precipitated by the addition of 10% molybdate solution. The precipitate is collected on a filter, washed with a hot solution containing 5% each of hydrochloric acid (21.5° B.) and ammonium chloride, and then with hot water until free from acidity. The precipitate may be weighed directly or its quantity determined by titration with sodium hydroxide solution or permanganate solution (after reduction with zinc), or it may be converted into ammonium magnesium phosphate and weighed as magnesium pyrophosphate.—W. P. S.

Cadmium and zinc; Experimental determination of the vapour pressure curves of molten — and the calculation of the chemical constants of cadmium, zinc, and monatomic bromine. H. Braune. *Z. anorg. Chem.*, 1920, 111, 109—147.

THE vapour pressure of molten cadmium up to 2 atm. is represented by $\log p = -5763/T - 1.28 \log T + 12.282$, whilst that of zinc is given by $\log p = -6655/T - 1.147 \log T + 12.046$. Both zinc and cadmium have a constant atomic heat over the range of temperature from the melting point to the boiling point. The values are 7.50 (cadmium), 7.24 (zinc). (Cf. J.C.S., Aug.)—J. F. S.

PATENTS.

Steel, particularly adapted for the manufacture of ball and roller bearings. Comp. d'Applications Mécaniques. E.P. 126,289, 23.4.19. Conv., 2.5.18.

THE steel contains C 0.85—1.5, Cr 0.5—2, and V 0.1 to 0.5%, a suitable composition being C 0.950, Mn 0.300, Si 0.150, Cr 1.200, V 0.250%, with sulphur and phosphorus as low as possible. To increase the tenacity and flexibility of the steel, and to facilitate certain forging operations, drawing, and annealing, one or more other metals, such as Ni, Co, Mo, Ta, or the like, may be added in a proportion not exceeding 0.25%.—T. St.

Steels; Alloy —. The British Thomson-Houston Co. From General Electric Co. E.P. 144,185, 4.11.19.

AN alloy containing about 16% B is produced by reducing a mixture of iron oxide and boric acid by aluminium, and this alloy is then added to molten steel to yield a product containing B 0.75—5%. By thus incorporating a relatively small amount of boron with chromium, tungsten, vanadium, etc., comparatively easily fusible special steels are produced which can be cast readily even into intricate forms substantially free from blow holes and other defects, and which still preserve the properties given by the alloying element exclusive of the boron.—T. St.

Iron ores; Treatment of —. C. R. Hayward, F. O. Stillman, and H. M. Schleicher, Assrs. to Moa Iron and Development Corp. U.S.P. 1,341,901, 1.6.20. Appl., 24.7.18.

IRON ore containing aluminium and one or more of the metals nickel, manganese, and chromium is subjected to a sulphating roast whereby a small proportion of the iron and a large proportion of the other metals are rendered soluble. On leaching, a richer iron ore residue is obtained and a liquor which on evaporation yields sulphates of iron and

the other metals. These salts are roasted, and from the resulting oxides alumina is recovered.

—J. W. D.

Iron and steel plates; Process for finishing —. C. Williams, Assr. to N. Nelson. U.S.P. 1,342,484, 8.6.20. Appl., 9.6.19.

THE plates, after pickling, are successively washed in a soapy solution, rinsed, annealed in the presence of sulphurous fumes, and subjected to the action of dry air. Finally, to give them a high polish, the plates are cold-rolled.—T. St.

Iron; Puddling —. T. F. Payne. U.S.P. 1,342,694, 8.6.20. Appl., 30.4.19.

THE metal is agitated in the furnace on horizontal longitudinal parallel lines whereby a combing or stratifying action is produced.—T. St.

Iron or steel articles; Process of colouring —. H. F. Jermain, Assr. to Winchester Repeating Arms Co. U.S.P. 1,342,910, 8.6.20. Appl., 7.1.20.

IRON or steel articles are made the anode and cathode alternately in an electrolytic bath consisting of a solution of an oxidising agent in an alkaline liquid, the opposing electrode being incorrodible. The articles are afterwards washed with hot water, dried, and rubbed with oil.—T. St.

Steel alloy. C. M. Johnson. U.S.P. 1,342,911, 8.6.20. Appl., 7.8.19.

THE alloy steel consists of iron with C 0.30—0.60, Mn not more than 0.80, Si 1.00—2.50, Cr 0.30—0.80, V 0.10—0.30, and Ni 1.50—3.50%.—T. St.

Ferrochrome; Production of low-carbon —. H. C. Sicard, Assr. to United States Ferro-Alloys Corp. U.S.P. 1,341,939, 1.6.20. Appl., 26.9.19.

A HIGH-CARBON ferro-chromium alloy is decarbonised by means of titanic oxide.—J. W. D.

Electric smelting furnace. I. Hole. E.P. 125,363, 6.3.19. Conv., 11.4.18.

CHARGING openings are arranged in the roof of the furnace on both sides of a central longitudinal row of electrodes, so that the sloping sides of the charge form a longitudinal groove at the bottom of which is the slag bath in which the electrodes dip without passing through the charge. A discharge outlet is provided so that the slag in the furnace is kept at a constant level.—A. R. P.

Furnace; Electro-metallurgical —. F. Louvrier. U.S.P. 1,342,636, 8.6.20. Appl., 5.4.19.

AN annular chamber surrounding the feeding column of the furnace leads into the reduction chamber, and means are provided for feeding coal dust on to shelves in this annular chamber.

—J. S. G. T.

Kilns for pyrites. J. L. Fairrie. E.P. 144,142, 14.8.19.

A NUMBER of kilns with fire-grates and working doors are arranged in a circle round a common flue into which the gases are drawn. The burnt ore falls on to sloping floors below the fire-grates and passes through swing doors to a common discharge pit at the base of the central flue, whence it is removed either continuously or intermittently by means of a conveyor, preferably of the drag har type. The conveyor can be withdrawn bodily for repairs. Additional air may be admitted through a port between the pit and the flue, which can be closed by an adjustable tile.—B. M. V.

Furnaces; Port construction for metallurgical —. G. F. Downs and H. F. Miller, jun. U.S.P. (A) 1,343,314 and (B) 1,343,315, 15.6.20. Appl., 30.3.18 and 15.5.19.

(A) Gas and air uptakes communicate with the in-

terior of the furnace, the air uptake by means of an air port, and the gas uptake by means of a water-cooled tubular metal flue opening into the air port. Adjustable means, operated from outside the furnace at a point above the air port, are provided for supporting the flue, so that its orifice is entirely surrounded by the air port. (u) The gas flue connecting the gas uptake with the interior of the air port is arranged to discharge across and at an angle to the upward path of the air coming through the air uptake.—T. St.

Electrolytic recovery of metals from their solutions. H. Wade. From The Central Mining and Investment Corp. E.P. 143,620, 21.2.19.

Is the electrolytic recovery of metals by passing the pregnant solution through a permeable cathode of fine porosity, oxygen is removed from the solution, e.g., by a vacuum pump or by a reducing agent, before passing it into the electrolytic cell.—J. W. D.

Metal alloy. C. B. Backer. U.S.P. 1,311,771, 1.6.20. Appl., 30.12.18.

As alloy consisting of Mg 85—98%, Al 15—14.0, and Zn 0.75—6.0%.—J. W. D.

Copper; Recovering — from its ores. C. J. A. Dalziel. U.S.P. 1,311,786, 1.6.20. Appl., 24.9.18.

Suitable proportions of finely crushed ore and an acid solution are converted into a pulp by aeration-agitation, and the pulp is caused to flow through a series of electrolytic cells, sedimentation in the cells being prevented by a blast of air introduced at the lower part of each cell. The barren pulp is discharged from the last cell.—J. W. D.

Copper; Process of extracting —. A. A. Ossa. U.S.P. 1,313,153, 8.6.20. Appl., 20.12.18.

Oxidised copper ores are leached with a solution containing sulphuric acid and the copper precipitated as iodide by hydriodic acid in presence of sulphur dioxide. The sulphuric acid formed in the latter reaction is used for the extraction of fresh ore, and hydriodic acid is regenerated from the iodide precipitate for addition to fresh copper sulphate solutions.—T. St.

Metallurgical process. [Treatment of copper ores.] W. E. Greenawalt. U.S.P. 1,344,127, 22.6.20. Appl., 28.11.17.

Mixed sulphide and oxide ores of copper are treated with a solvent for the oxides, a flotation agent is added, and the pulp electrolysed, using a current density high enough to give a loose deposit of copper which with the copper sulphide is floated by means of the gases liberated.—A. J. H.

Metallurgical process. W. E. Greenawalt. U.S.P. 1,342,804, 8.6.20. Appl., 21.12.16. Renewed 2.9.19.

As electrolyte containing ferric iron is agitated with a (copper) sulphide reducing agent practically free from iron. A portion of the mixture is continuously withdrawn, the sulphide separated and returned to the agitator, and the reduced electrolyte returned to the electrolytic bath.—J. S. G. T.

Chilian mill; Multiple-process —. C. C. Lane. U.S.P. 1,342,917, 8.6.20. Appl., 12.12.16.

In a Chilian mill the framework that drives the grinding rollers is provided with a heavy and evenly balanced monolith and above that a tank, which may be used for cyanide treatment of the ore pulp, the weight of both being supported by the grinding rollers and assisting grinding.—B. M. V.

[Crucible] furnace. A. C. Osborn, jun. U.S.P. 1,343,470, 15.6.20. Appl., 26.1.20.

A CRUCIBLE furnace comprises an upper section hinged to a lower section carrying a removable sup-

porting member for the crucible, and means for moving one section relatively to the other, gas jets forming a part of the upper section and connected to and fed by a supply pipe and a main supply pipe, and means for automatically providing an air-tight connexion between the two pipes when the upper section is moved to its operative position.—A. de W.

Ores; Treating —. G. L. Collord. U.S.P. (a) 1,343,249 and (n) 1,344,250, 15.6.20. Appl., 9.5.19.

(a) THE moist ore is treated with a liquid, less volatile than water, which will spread throughout the mass and form a thin film round the particles. The ore is then partially dried. (n) The moist ore is partially dried and then mixed with an oleaginous material to agglomerate the fine particles.—A. R. P.

Ores or other materials; Process and apparatus for concentrating —. S. H. Dolbear, Assr. to Minerals Separation North American Corp. U.S.P. 1,343,313, 15.6.20. Appl., 14.11.18.

A COLUMN of liquid containing a mixture of floatable and unfloatable materials in a suitably divided condition is treated with a gas in such a manner that gas in the form of bubbles rises in the liquid and becomes attached to the floatable material. These bubbles are then diverted into a gaseous medium at a point where the pressure in the column is greater than in the gaseous medium.—T. St.

Zinc, copper, cadmium; Process of treating residues containing —. J. O. Elton and R. B. Caples, Assrs. to Anaconda Copper Mining Co. U.S.P. 1,343,619, 15.6.20. Appl., 5.1.20.

Zinc sulphate solutions containing copper and cadmium are treated with zinc to precipitate the latter two metals. The precipitate is treated with just sufficient sulphuric acid to dissolve the zinc and cadmium, and the filtered solution is again treated with zinc to precipitate the cadmium.—A. R. P.

Lead and like ores and products; Smelting —. T. W. Cavers, Assr. to Garred-Cavers Corp. U.S.P. 1,343,656, 15.6.20. Appl., 9.8.18.

Oxidised lead ores or the like are mixed with a carbonaceous reducing agent and smelted in a blast furnace by means of powdered coal fed into the blast.—A. R. P.

Metal-plating; Process and apparatus for —. R. J. Piersol. U.S.P. 1,343,842, 15.6.20. Appl., 3.1.20.

THE metal to be plated is treated with the plating metal *in vacuo* at a temperature between the melting points of the two metals.—T. St.

Furnace; Galvanising —. C. A. Porath. U.S.P. 1,343,843, 15.6.20. Appl., 7.7.19.

THE galvanising material is contained in a tank above a layer of a substance of higher specific gravity, and means are provided for heating the bottom of the tank.—T. St.

Melting furnaces; Lids for —. A.-G. Brown, Boveri & Co. E.P. 132,785, 2.9.19. Conv., 14.9.18. Addn. to 131,887.

Furnace for hardening high-speed steel and the like. S. H. Gush. E.P. 144,486, 23.6.19.

Electric arc welding operations; Metallic electrodes for use in —. C. J. Holslag. E.P. 144,333, 11.12.18.

Steel alloy. Stahlwerke R. Lindenburg A.-G. E.P. 144,326, 16.8.16. Addn. to 103,810.

XII.—FATS; OILS; WAXES.

Catalysis. XIII. Contact potentials and dielectric capacities of metals in relation to the occlusion of hydrogen and hydrogenation. W. C. McC. Lewis. Chem. Soc. Trans., 1920, 117, 623—638.

FROM a consideration of the solubility of hydrogen in certain metals it is inferred that metals in general possess finite dielectric capacities, and values for a number of metals have been obtained from the critical increments of dissociation of hydrogen dissolved therein. The insolubility of hydrogen in certain metals is regarded as being due to the inability of these metals to dissociate the gas, and such metals may be expected to function as negative catalysts when deposited on the surface of active metals in hydrogenation. The dissociating power of a metal for hydrogen depends on both the dielectric capacity and the existence in the metal of radiation of a sufficiently short wave length. As this is related to the magnitude of the atomic latent heat of fusion of the metal, a measure of the dissociating power is given by the product of the dielectric capacity and the latent heat of fusion. The mechanism of hydrogenation of olein by nickel or other metals is regarded as consisting primarily of the dissociation and solution or adsorption of hydrogen by the particles of metal with which the olein molecules already activated by virtue of their temperature collide. A simple collision formula reproduces in so far as order of magnitude is concerned the observed unimolecular velocity constants obtained by Thomas (J., 1920, 10 τ). It is concluded that in the hydrogenation of olein and of similar substances adsorption of the unsaturated compound on the metal does not take place, the adsorption being restricted to the metal-hydrogen compounds.—G. F. M.

Cod-liver oil; The sulphuric acid test for —. P. J. de Kadt. Pharm. Weekblad, 1920, 57, 756—758.

COD-LIVER oil which has been bleached by means of bleaching agents such as fuller's earth, animal charcoal, etc. fails to give a violet coloration with sulphuric acid, the impurities in the oil which give this reaction having been absorbed by the bleaching agent. When the sulphuric acid test is made on a porcelain slab, the best results are obtained with acid of sp. gr. 1.72. It is, however, preferable to employ a 5% solution of the oil in carbon bisulphide and then to test it with sulphuric acid of sp. gr. 1.84.—W. J. W.

Soya bean oil. W. H. Low. J. Ind. Eng. Chem., 1920, 12, 572—573.

A SAMPLE of filtered soya bean oil had iodine value (Wijs) 138.45, and contained 94.96% fatty acids, 1.16% unsaponifiable matter, and 10.37% glycerol (calculated from the saponification value, after making allowance for free fatty acids).—C. A. M.

Soap solutions and gels; Direct experimental determination of the concentration of potassium and sodium ions in —. C. S. Salmon. Chem. Soc. Trans., 1920, 117, 530—542.

THE theory of colloidal electrolytes (J., 1918, 249 τ) is supported by the results of E.M.F. determinations, both from direction and magnitude of the diffusion potential between soap and potassium chloride and by comparison with known concentra-

tions of potassium and sodium chlorides. The concentrations of sodium and potassium ions already deduced from a comparison of conductivity data and osmotic activity are confirmed by direct measurements for a selection of typical cases at 18° and 90° C., the solutions studied being potassium laurate, potassium oleate, and sodium oleate. Gelation of sodium oleate does not influence the results obtained.—G. F. M.

Emulsions. 1. New method of determining the inversion of phases. S. S. Bhatnagar. Chem. Soc. Trans., 1920, 117, 512—552.

A METHOD for determining the inversion of phases and the identification of the two types of emulsion is based on the greater electrical conductivity of the oil-in-water type and the sudden rapid rise in the resistance of the emulsion at the point of inversion into the water-in-oil type, a sensitive milliammeter being used to obtain the indications. Both types of emulsion are formed by sodium or potassium hydroxide with olive oil and with paraffin oil, and the inversion points were determined in each case with different concentrations of alkali. At concentrations below $N/500$ the divalent alkalis gave results practically identical with the univalent alkalis, but at greater concentrations the electrolytic effect predominates over the volume-ratio effect and the formation of the water-in-oil type is favoured. Homogeneous emulsions of particles of uniform size were prepared. Using weak alkalis the volume ratio was constant at 7.4:26, and the equation for closest packing appears to hold in them. A preliminary study was made of the effect of different fatty acids and of a few electrolytes on the emulsion equilibrium.—G. F. M.

Oil-cake. Sabalitsebka. See XIXa.

PATENTS.

Oils or fats; Process for neutralising —. A. G. Bloxam. From M. Arbini. E.P. 144,176, 17.10.19.

OILS or fats are neutralised with dry caustic alkali or calcined alkali carbonate, or with alkali peroxide or percarbonate, with the exclusion of water, the water formed in the reaction being removed, e.g., by a vacuum pump. The neutralised oil is then separated from the dry soap (which is ready for use) by means of an anhydrous solvent (methylal or acetone).—C. A. M.

Hydrogenising oils and fats; Apparatus for —. Blair, Campbell and McLean, Ltd., D. A. Blair, and J. L. Ferguson. E.P. (a) 144,478, 23.8.19. (b) 144,479, 19.6.19.

(A) THE mixture of oil or fat and catalyst is placed in a circular steel high-pressure vessel fitted with a vacuum pipe and means for introducing hydrogen, heated externally by a steam, gas, or flue jacket. A pump raises the mixture from the bottom to the top of the vessel, wherein it falls on to the uppermost of a number of horizontal, preferably annular, dish-shaped plates or partitions, each having a central opening through which the liquid falls into the interior of one of a number of buckets or reservoirs fitted to and adapted to be rapidly rotated in unison on a central shaft. The walls of the buckets are provided with brushes having short flaring bristles fitted through and connected to the insides of the buckets, whereby the centrifugal force of rotation distributes the liquid against the brushes and then forces it outwards in a fine spray against the inner sides of the reaction vessel. The next lower annular partition then collects the sprayed oil, and its central opening in its turn directs it to the underlying bucket. The lower part of the rotating shaft carries a stirring device, which is in combination with angle iron or similar device attached to the reaction vessel to prevent the liquid attaining circular motion, and an agitator to pre-

vent settlement of the catalyst in the bottom of the vessel. (B) The apparatus described in (A) comprises in addition an inner vertical cylinder or sectional cylinders with inwardly projecting perforated baffles, perforated sectional division plates, and bevel division plates, arranged concentrically about the shaft which carries the distributing reservoirs, and geared to rotate in a similar or opposite direction to the central shaft. The outside of the cylinder has openings which act as gas suckers and force gas against the flow of spray of liquid directed by the central rotating reservoirs.—A. de W.

Fatty oils; Process of treating [hydrogenising] —. C. Ellis. U.S.P. 1,313,255, 15.6.20. Appl., 17.12.15.

FATTY oils containing unsaturated components are brought into contact with a stationary catalytic agent containing active catalyst materially over 1% of the weight of oil which would be in contact with the catalyst at any given time, in the presence of a counter-current of hydrogen at such pressure that no material amount of the metal of the catalyst can remain in combination with the fatty acid of the oil whilst the oily material is cooled to the temperature below which objectionable side reactions occur.—A. de W.

Hydrogen-circulation process [for hydrogenating oils]. C. Ellis. U.S.P. 1,342,668, 8.6.20. Appl., 14.10.16.

THE current of gas containing hydrogen which has circulated through the unsaturated material and catalyst is passed into a larger volume of gas suitable for hydrogenation, and at least the greater part of it left in contact with water for a longer period than it was in contact with the organic material.—C. A. M.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Varnishes; Wearing quality of — compared with their physical and chemical analyses. W. T. Pearce. J. Ind. Eng. Chem., 1920, 12, 552—555.

GOOD grades of exterior and interior varnishes were applied to outside doors exposed to different aspects, and after 9 and 12 months the lustre and condition of the coatings were noted, and compared with viscosity, sp. gr., elasticity, time of drying, etc., and with the composition (total resins, rosin, oils, turpentine, turpentine substitutes, and ash) of the original varnishes. The varnished panels were also tested by placing a moist felt sponge at one end, and if the varnish failed to whiten, the panel was placed in water for definite periods, and allowed to dry. There appear to be definite relationships between the values for viscosity, surface, elasticity, and the sponge test and the results of the service tests. Details of the methods of analysis are given.—C. A. M.

Paracoumarone resin; Use of — in varnishes. W. W. King, F. W. Bayard, and F. H. Rhodes. J. Ind. Eng. Chem., 1920, 12, 549—552.

PARACOUMARONE resins prepared by the polymerisation of the coumarone and indene in aromatic naphthas are now obtainable for commercial purposes of a lighter colour than formerly. Grades suitable for varnish melt between 125° and 145° C.; they retard the polymerisation of tung oil, and satisfactory varnishes may be made by heating a mixture of linseed and tung oils (5 to 40 galls.) with the coumarone resin (100 lb.) at about 2.5° C. per min. to 290°—320° C., then cooling the mixture, adding a suitable quantity of thinner (coal tar solvent), continuing the cooling to below 100° C., and finally adding drier solution (100 pts. of cobalt linoleate

and 84.2 pts. of raw linseed oil heated for 2 hrs. at 200° C., treated with 42.1 pts. of tung oil, again heated, and poured into 600 pts. of coal tar solvent). The resulting varnishes are clear, free from sediment, set in 3 hrs., and dry hard within 20 hrs. The films are brilliant, of a light colour, and resist the action of hot and cold water, ammonia, soap, vinegar, fruit acids, etc. Cobalt linoleate may be replaced by a manganese drier (acetate or linoleate) but a larger proportion is required.—C. A. M.

PATENTS.

Pigments and method of making same. V. M. Goldschmidt, Assr. to Titan Co. A./S. U.S.P. 1,343,446, 15.6.20. Appl., 27.9.18.

TITANIUM compounds are treated with liquids containing a foreign colouring substance in solution or suspension.—A. de W.

Pigment containing titanium-oxygen compound. V. M. Goldschmidt, Assr. to Titan Co. A./S. U.S.P. 1,343,447, 15.6.20. Appl., 10.5.17.

A SOLUTION containing titanium compounds and amorphous silica is evaporated to dryness and the residue heated to expel water and sulphuric acid, and to convert the titanium dioxide into crystalline form.—A. de W.

[Titanic oxide] pigments; Process of producing —. R. Nielsen and V. M. Goldschmidt, Assrs. to Titan Co. A./S. U.S.P. 1,343,468, 15.6.20. Appl., 16.5.17.

A MATERIAL suitable for use as or in the manufacture of a pigment comprising iron oxide with smaller amounts of titanium oxide and calcium sulphate, titanate, and ferrite, is obtained by evaporating a solution containing iron and titanium sulphates from which titanium hydroxides have been precipitated, heating the residue to drive off sulphuric anhydride, adding calcium carbonate to the residue, and so heating the resultant mixture that the SO₂ radicle present is combined to form calcium sulphate, and calcium titanate and ferrite are formed.—A. de W.

Titanium products and the process of producing same from precipitated titanium hydrates. R. Nielsen and V. M. Goldschmidt, Assrs. to Titan Co. A./S. U.S.P. 1,343,469, 15.6.20. Appl., 12.10.17.

THE undesired acid substance contained in titanium hydroxides is eliminated by treating them with a compound of a metal which reacts with the former to produce a number of compounds, one being a neutral and relatively insoluble salt and another a gas.—A. de W.

Turpentine substitute and process of making same. R. C. Bone, Assr. to Esteva-Ruiz and Co. U.S.P. 1,343,387, 15.6.20. Appl., 14.3.18.

KEROSENE is treated with calcium carbide and water simultaneously, the mixture allowed to settle, bleaching powder and hydrochloric acid are added to the liquid which separates, the resultant mixture is allowed to stand, and the supernatant liquid decanted and mixed with calcium oxide.—A. de W.

Phenolic condensation products; Manufacture of —. C. A. Nash. U.S.P. 1,343,575, 15.6.20. Appl., 10.3.19.

A MIXTURE of a fibrous filler and a relatively small quantity of a slowly-volatile solvent for a fusible phenolic condensation product is mixed with a binder consisting of a substantially anhydrous phenolic condensation product containing at least two phenolic groups to each methylene group and a non-volatile methylene body in sufficient quantity

to give to the moulding mixture approximately one phenolic group to each methylene group; the product is subjected to a quick-moulding operation to form a body, and the moulded article after removal from the mould is then hardened by prolonged heat treatment to a hard and substantially infusible form.—A. de W.

Linoleum, liverusta and the like; Preparation of a substitute for —. F. Eckl. G.P. 319,473, 20.6.18.

PLASTIC masses of glycerin and glue hardened with tannin are mixed while hot with a product obtained by boiling wood tar with lime. The resulting plastic material does not dry to a hard mass, but becomes coated with a resistant elastic skin.—C. A. M.

Linoleum substitute; Preparation of —. Deutsche Konservierungsges. m.b.H. G.P. 319,782, 29.11.16.

JUTE or other fabric is coated with cork meal, wood meal, etc., and a binding agent composed of highly chlorinated products of naphthalene, which is mixed in the usual way, while hot, with basic substances, and applied to the fabric with the aid of hot highly-chlorinated naphthalene.—C. A. M.

Printers' roller composition; Apparatus for reclaiming used —. T. H. Grozier. U.S.P. 1,344,270, 22.6.20. Appl., 10.11.19.

SEE E.P. 121,941 of 1918; J., 1919, 378A.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

PATENTS.

Latex; Method of coagulating —. T. Burney. From E. Nixon-Westwood. E.P. 144,133, 30.7.19.

LATEX is coagulated in a rectangular tank coated or enamelled with acid-resisting material and provided with removable vertical partitions which are introduced after the mixing of the latex and the coagulant; the partitions cause the formation of the coagulum in sheets of convenient size.—D. F. T.

Rubber; Process for vulcanising — and product obtained thereby. I. Ostromislensky, Assr. to New York Belting and Packing Co. U.S.P. (A) 1,342,457 and (B) 1,342,458, 8.6.20. Appl., 29.7 and 24.11.16.

(A) THE harmful effect of the vulcanising agent on an organic dye mixed with rubber is avoided by the additional presence of a substance capable of inducing vulcanisation and of preventing injury to the colouring matter. (B) Rubber is subjected to the action of sulphur and an organic vulcanising agent containing oxygen.—D. F. T.

Rubber vulcanisation and the product thereof. S. B. Molony, Assr. to Michigan Chemical Co. U.S.P. 1,343,224, 15.6.20. Appl., 17.6.19.

THE vulcanisation of rubber is accelerated by the presence of a compound of carbon bisulphide with amines derived from beet sugar residue.—D. F. T.

Dimethylbutadiene. G.P. 319,505. See XX.

XV.—LEATHER; BONE; HORN; GLUE.

Chamoising. IV. W. Moeller. Collegium, 1920, 69—79. Chem. Zentr., 1920, 91, 11., 786. (Cf. J., 1919, 782 A.)

THE author has prepared ozonides from oleic acid and marine animal oil by the Harries method, and investigated their tanning properties alone and in mixture with phenol, the composition of the leather thus produced and of the substances taken

up by the hide. He concludes that the tannage is effected by the undecomposed ozonides, and that only a portion of the oxygen is split off with the formation of peroxides, anhydrides, and lactones which constitute the peptised substance in the tannage.—D. W.

PATENTS.

Iron-tanned leather; Preparation of tough, durable — M., E., and R. Stecher. G.P. (A) 319,705 and (u) 319,859, 11.1.16 and 11.10.17. Addus. to G.P. 314,487 and 314,885 (J., 1920, 121 A, 199 A).

(A) SOLUTIONS of ferrous salts are oxidised with excess of chlorine compounds, preferably chlorates or chloric acid, free from iron. (u) The oxidised iron solution is mixed with solutions of vegetable tanning materials or synthetic tannins, and used for tanning purposes. This process gives a smoother grain than that of the original patent.—D. W.

Condensation products of N-aryl-sulpho derivatives of aromatic aminosulphonic acids [tanning agents]; Preparation of — Ges. für Chem. Ind. in Basel. G.P. 319,713, 12.2.15.

CONDENSATION products of formaldehyde with N-aryl-sulpho derivatives of aminosulphonic acids of the benzene or naphthalene series are readily soluble in water, precipitate albumin from its solutions, and tan animal hides.—C. A. M.

XVI.—SOILS; FERTILISERS.

Soils; The absorbent power of — with respect to manganese. P. Nottin. Comptes rend., 1920, 171, 44—47.

CALCITE is not acted on by a 1% solution of manganoous chloride, whereas aragonite and ktypeite are readily attacked, the calcium going into solution and the manganese being precipitated. The different absorbent powers of soils for manganese salts are to be attributed to a different crystallographic state of the calcium carbonate present in the soils.—W. G.

Soil bacteria; The potential biochemical activity of the spores of — J. R. Neller. Soil Sci., 1920, 9, 329—340.

THE accumulation of ammonia and the production of carbon dioxide resulting from inoculating a sterile soil with soil infusions which have been heated to 85° C. for 10 mins. indicate that the bacterial spores of the soil are capable of energetic activity when supplied with sufficient food and moisture. Evidence is not available as to how they would withstand competition from actinomycetes, non-sporulating bacteria, and fungi in a normal soil flora.—W. G.

Alkali content of soils as related to crop growth. F. T. Shutt and E. A. Smith. Trans. Roy. Soc. Canada, 1919, 13, [iii.], 233—242.

A CONTINUATION of work on the relation of alkali content of Canadian soils to crop growth (see J., 1919, 84 A).—J. R. P.

Nitrogen fixation; Symbiotic — as influenced by the nitrogen in soil. W. A. Albrecht. Soil Sci., 1920, 9, 275—327.

EXPERIMENTS with soya beans and cowpeas indicated that nitrogen fixation will take place in a soil containing large amounts of nitrogen either in the form of nitrates or as organic matter. No injurious effects on nitrogen fixation were observed following on applications of nitrates such as are used in practice. Nodules were produced when large amounts of organic nitrogen were present, and good growth of the leguminous plants was obtained even when sufficient organic matter was present to give large

losses of volatile nitrogen from the soil. Varying the amount of total nitrogen in a soil failed to exert any varying influence on the amount of nitrogen fixed.—W. G.

Nitrogenous fertilisers; Field experiments on the availability of —, 1908—1917. J. G. Lipman and A. W. Blair. Soil Sci., 1920, 9, 371—392.

EQUIVALENT amounts of nitrogen were applied to plots in the form of sodium nitrate, calcium nitrate, ammonium sulphate, calcium cyanamide, dried blood, dried fish, and concentrated liquid manure. One half of each plot was limed and the other half left unlimed. The average yields of dry matter and the percentage of nitrogen recovered were greater with the mineral nitrogenous fertilisers than with the organic manures. Of the four mineral fertilisers sodium nitrate gave the largest yields of dry matter and highest percentage recovery of nitrogen on the unlimed section, and ammonium sulphate the highest on the limed section. Similarly dried fish and dried blood gave respectively the highest returns of the organic manures on the two sections. In all cases there was an average loss of at least two-thirds of the applied nitrogen.—W. G.

Calcium cyanamide; Determination of cyanamide and dicyanodiamide in —. Marqueyrol, P. Lorient, and L. Desvergues. Ann. Chim. Analyt., 1920, 2, 164—167.

VOLUMETRIC methods for the determination of cyanamide and dicyanodiamide depending on the precipitation of the silver compounds in ammoniacal and nitric acid solution, respectively, are untrustworthy owing to the variable silver content of the precipitates. The silver precipitates, however, contain the whole of the cyanamide nitrogen, or the dicyanodiamide nitrogen, and determination of the nitrogen in the precipitates by the Kjeldahl method, as recommended by Caro, gives an accurate measure of the two forms of nitrogen. (Cf. J., 1911, 23, 1129.)

—W. P. S.

Plant juices; The reaction of —. A. R. C. Haas. Soil Sci., 1920, 9, 341—369.

THE reaction of the juice of a plant appears to be affected by changes in illumination, soil solution, age of the plant, and other conditions. The degree of maturity of the plant seems to be an important factor in the degree of actual acidity attained. It is shown that the actual reaction of the juice of many agricultural plants is distinctly acid. The juice of the younger portions of a plant usually has a lower actual acidity than that of the older portions.—W. G.

PATENT.

Sandy soils; Improvement of —. H. Stoltzenberg. G.P. 319,634, 13.5.19.

AMMONIUM fluoride is distributed over the soil, which is then harrowed. The treatment is repeated until the particles of sand have been sufficiently corroded, when they will have an increased absorptive power. The fluoride can be removed by irrigation, prolonged exposure, or chemical treatment.

—D. W.

XVII.—SUGARS; STARCHES; GUMS.

Raw sugars; Deterioration of Cuban — in storage. N. Kopeloff and H. Z. E. Perkins. J. Ind. Eng. Chem., 1920, 12, 555—558.

A NUMBER of bags of Cuban raw sugar were examined chemically and bacteriologically at intervals during 5½ months, at the end of which period it was found that loss of sugar had occurred in all owing

to the action of micro-organisms. In those samples in which initially the number of micro-organisms had been high, deterioration had subsequently been rapid, and some of the highest counts occurred with sugars having factors of safety (moisture/[100—polarisation]) less than 0.30 (cf. J., 1919, 592 A). It is suggested that it may be possible to predict the keeping qualities of a sugar from the number of micro-organisms present; when more than 100 per grm. are counted, and when the factor of safety is greater than 0.2, subsequent deterioration may be expected.—J. P. O.

Carbonatation of beet juices; Microscopical investigation of the —. H. Claassen. Z. Ver. deuts. Zuckerind., 1920, 203—223.

On carbonating a pure solution of calcium saccharate, it is possible to obtain the calcium carbonate in a crystalline or partly crystalline state; but in the case of raw beet juice treated with milk of lime under ordinary factory conditions the precipitate is almost entirely amorphous. During the second carbonatation, however, that is, after filtering off the scum and passing in carbon dioxide to remove the lime still in solution, the precipitate obtained is largely composed of well-formed crystals, mostly rhombohedral. From the point of view of ready filtration of beet carbonatation scums, it is of secondary importance whether the calcium carbonate be in the form of crystals or amorphous grain, the essential condition being the even admixture with the adsorbed colloids of a sufficient amount of calcium carbonate to render the mass porous.—J. P. O.

Beet syrup; Production of [edible] — in beet sugar factories. H. Claassen. Ver. Deuts. Zuckertech., May, 1920. Chem.-Zeit., 1920, 44, 443.

WHILST in beet syrup factories proper, the juice is extracted from the steamed beets by pressure, it is possible to employ the much less costly diffusion process, with certain modifications. The juice is generally acidified with sulphuric acid, but a finer flavour is produced by spontaneous acidification during the diffusion process, for which purpose diffusion may be conducted very slowly or the freshly charged slices may be steamed. The filtered acid juice may be concentrated without excessive frothing by employing a high vacuum and maintaining brisk ebullition. A further heating, e.g., at 104°—108° C., is necessary to effect sufficient inversion to prevent subsequent crystallisation. When the proportion of sucrose has been reduced to not more than 1.5—1.6 times the moisture-content, the syrup should be cooled rapidly to prevent further inversion. Syrups suitable for human consumption may also be similarly produced from beet factory syrups.—J. H. L.

Cane juice; Hot sulphitation of limed —. W. H. T. Harloff. La. Planter, 1920, 64, No. 1, 14.

In order to avoid the formation of calcium sulphite scale on the tubes of heaters in which limed juice which has been sulphited in the cold is raised to 50°—60° C., the following procedure is advised: After heating to 80°—85° C., the raw juice is limed and sulphited simultaneously, conditions being so adjusted that the inflowing gas thoroughly mixes the contents of the tank, while the rate of flow of the milk of lime is such that the liquid is substantially neutral or only very slightly acid to phenolphthalein paper. On completing saturation, the juice is passed through the heaters, and finally is allowed to settle as usual. In this way scale formation in the heater tubes is very much less, settling is more rapid, and the juice is lighter in colour than when the ordinary method is used.

—J. P. O.

Invert sugar; Determination of — in presence of sucrose, by Bruhns' method. P. Beyersdorfer. Z. Ver. Deuts. Zuckerind., 1920, 259—271.

A CRITIQUE of Bruhns' method (Zentr. Zuckerind., 1919, 34, 621) in which, under prescribed conditions, 20 c.c. of sugar solution is boiled with 20 c.c. of Fehling solution (Soxhlet's formula) and the un-reduced copper is determined by treating the cooled solution first with potassium thiocyanate and potassium iodide and then with acid and finally titrating with thiosulphate solution, the results being interpreted by means of tables according to the amount of sucrose present. With fairly pure beet products, containing from 0.05 to 1.3% of invert sugar, it gave results in close agreement with Herzfeld's method. The precise determination of the end point of the titration required considerable practice, and duplicate determinations differed in some cases by 0.2 c.c. in the volume of thiosulphate required. Comparative determinations of reducing sugar in beet molasses by Bruhns', Beyersdorfer's, Schrefeld's, and Hiller's methods, showed occasional small differences between all, which are attributed to the presence of reducing substances other than invert sugar in molasses.

—J. H. L.

Sucrose; Alteration in volume during the inversion of —. N. Schoorl. Z. Unters. Nahr. Genussm., 1920, 39, 113—121.

WHEN 1 mol. of sucrose is hydrolysed, the 18 g. of water required undergoes a contraction of 6.9 c.c., which corresponds with a contraction of 0.5 c.c. for 26 g. of sucrose per 100 c.c. of solution. The extent of the contraction varies slightly with the catalyst used; it is greatest with oxalic acid and invertase and least with hydrochloric acid. The relation of the contraction to the determination of sugars by means of the sp. gr. is discussed.—W. P. S.

Maple products; Analysis of —. II. Composition of maple syrup and of maple sugar sand and the detection of adulteration of the syrup. J. F. Snell. Trans. Roy. Soc. Canada, 1919, 13, [iii.], 221—231.

THE average content of calcium malate in washed maple sugar sand was found to be 70%, corresponding with 55% of malic acid (cf. J., 1911, 980). In samples received in 1914 an average of 47.4% of malic acid was found. The recovery in laboratory experiments was 75% of the acid as shown by analysis. Adulteration of maple sugar with refined sugar leaves the sucrose content unchanged, but reduces the percentages of non-sugar constituents. Detection of adulteration is based on the content of one or more non-sugar constituents. The salts are most abundant, and the conductivity method of estimating these is preferred to others except the volumetric lead method (J., 1916, 482). Tables of standard values are given.—J. R. P.

Sucrose; Biochemical preparation of — from gentianose. E. Bourquelot and M. Bridel. Comptes rend., 1920, 171, 11—15.

EMULSIN freed from invertase decomposes gentianose, giving dextrose and sucrose. The sucrose can be isolated in a pure crystalline state after converting the dextrose into β -methylglucoside.—W. G.

Radium radiation; Action of — on sucrose and agar. A. Fernau. Biochem. Zeits., 1920, 102, 246—251.

SUCROSE is inverted by the action of radium radiation. Agar submitted to the same influence liquefies with the production of sugars—most probably galactose and arabinose—which strongly reduce Fehling's solution. The chemical change in both cases is due to the primary action of the radium.

—S. S. Z.

PATENT.

[Steffens' process.] Method of recovering by-products from waste liquors [from —]. G. M. Bradford and J. E. Broadhead. U.S.P. 1,312,737, 8.6.20. Appl., 16.9.18.

THE waste liquor, concentrated to about 30° B. (sp. gr. 1.26), is subjected to the action of an electric current of sufficient intensity to produce an arc in the liquid, whereby evaporation and electrolysis are produced, followed by complete combustion. The volatile products are recovered as well as the residue, which contains potash.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Mucors; Action of different acids on the growth of —. Bettinger and Delaval. Bull. Assoc. Chim. Suer., 1920, 37, 254—261.

IN employing mucors for the saccharification of distillery mash the starch is first liquefied either by diastase or by acids (cf. J., 1920, 244A). In rice mash liquefied by diastase without any addition of acid, growth of the mucus is less than in mash treated with a small quantity of hydrochloric, sulphuric, oxalic, tartaric, phosphoric, succinic, or acetic acid, equivalent to about 5 l. of commercial hydrochloric acid per 1000 kg. of grain. The optimum amount varies with different acids, and is in general greater the lower the degree of ionisation of the acid; if the optimum is exceeded growth is more or less inhibited. Acetic and succinic acids, which are excretion products, act favourably on growth at very low concentrations, but with increasing concentration they exert an inhibitive action much greater than can be accounted for by their degree of ionisation.—J. H. L.

Yeast (Saccharomyces thermantitonus). H. von Euler and I. Laurin. Biochem. Zeits., 1920, 102, 258—268.

A STRAIN of *Saccharomyces thermantitonus* emanating from the Institut für Gärungsgewerbe, in Berlin, was examined by the authors for its growth, fermentation, and inversion capacities. They found that the limits of temperature characteristic for this species have altered after 15 years' cultivation in the laboratory on thin beer wort. A similar observation has been previously made by the authors on a strain of *Saccharomyces thermantitonus* which came from Jørgensen's laboratory. It is, therefore, concluded that the yeast during the years of cultivation in the laboratory adapted itself to a lower temperature.—S. S. Z.

Catalase; Chemical kinetics of —. E. Yamazaki. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 59—95.

THE enzymes from *Glycin hispida*, Maxim, and from the blood of cattle catalyse hydrogen peroxide according to the same laws as that from *Phyllostachys mitis*, Riv. (cf. J. 1920, 463 A), but the temperature coefficients are different. The rate of decomposition of hydrogen peroxide by catalase is reduced to zero by the addition of $N/1200$ mercuric chloride, potassium cyanide, hydroxylamine, and phenylhydrazine; strong oxidising agents like potassium chlorate, potassium nitrate, and potassium bichromate retard the reaction very much, whilst manganous sulphate, soluble starch, glycocoll, and sucrose accelerate it. (Cf. J.C.S., Aug.)—J. F. S.

Urease; Chemical kinetics of —. E. Yamazaki. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 97—136.

UREASE from soya beans decomposes urea in two stages thus: $CO(NH_2)_2 + NH_4CO_2NH_2 \rightarrow (NH_4)_2CO_3$. The reaction is retarded by the addition of electrolytes such as hydrochloric acid, silver sulphate, and mercuric chloride. (Cf. J. C. S., Aug.)—J. F. S.

Enzyme action; Mechanism of —. E. Yamazaki. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 137—142. A NUMBER of hypotheses of the mechanism of enzyme action are discussed.—J. F. S.

Wine analysis. W. Fresenius and L. Grünhut. Z. anal. Chem., 1920, 59, 49—79.

DIRECTIONS are given for determining the sp. gr., alcohol content, and total solids in the same sample of wine. A table is given for correcting the sp. gr. to 15°/4° C., when the determination has been made at 17.5°/4° C.—W. P. S.

Acetone and butyl alcohol; Seed-culture methods in the production of — by a fermentation process. H. B. Speakman. J. Ind. Eng. Chem., 1920, 12, 581—587.

IN the production of acetone and butyl alcohol by fermentation (J., 1919, 155 r) the acidity of the mash rises for 15 hrs. and then falls for the same period, except in the presence of certain organisms which cause abnormal rise in the acidity. The seed cultures should be transferred when the acidity begins to fall. The seed-culture plant is made of copper; this soon becomes coated with a black deposit, which reduces the formation of toxic metallic salts. Laboratory cultures are started from the products of a fermentation containing maize residues and spores of the bacillus in a tube which has been kept for 3 months in a dry place. Mash contained in tubes constricted in the middle is inoculated from this first tube, and the tubes sealed at the constriction. After 24 hrs. the tubes are opened and incubated at 37° C., the gas developed forming an anaerobic atmosphere. From these tubes flasks of 300 c.c. of 5% mash are inoculated next day, and larger quantities from these. The period of the final fermentation is reduced by keeping the number of generations between the spore culture and fermentation as few as possible. After inoculation of the main mash (24,000 galls.) from a seed tank (500 galls.), the valves of the vessel are closed until the fermentation begins, and a slight pressure is then maintained by regulating the flow of gas through the air-valve.—C. A. M.

PATENTS.

Alcohol; Manufacture of — [from rice straw]. A. B. C. Rogers and C. H. Bedford. E.P. 144,079, 27.5.19.

RICE straw, with or without rice husk, is steamed, preferably with superheated steam, then converted into pulp and digested with dilute acid, and the liquid obtained is neutralised and fermented. The steaming process may be effected in two stages, the uncondensed steam from the second stage being utilised for the preliminary steaming; and during the steaming process the material may be subjected to the action of hydrochloric acid vapour or atomised calcium hypochlorite and chlorine with or without hydrochloric acid. An arrangement of plant is also claimed.—J. H. L.

Alcohol-reduced beer; Manufacture of —. H. Heuser. Reissue 11,889, 22.6.20, of U.S.P. 1,302,551, 6.5.19. Appl., 3.7.19.

SEE J., 1919, 551 A.

XIXA.—FOODS.

Milk; Pasteurisation of —. Orla-Jensen. Milchw. Zentr., 1920, 49, 45—53. Chem. Zentr., 1920, 91, ii., 780.

THE low pasteurisation method (heating at 60°—70° C. for 30 mins.) is the best for milk intended for infants' food and for cheese making, since the enzymes are not destroyed. Cream for butter making should be heated at 95° C. for 1 min. and then

cooled rapidly, whilst milk used as a medium for the culture of lactic acid bacteria should be pasteurised by heating at 85° C. for 1 hr. (Cf. Ayers, J., 1916, 323.)—W. P. S.

Milk serum obtained by spontaneous curdling. J. Grossfeld. Z. Unters. Nahr. Genussm., 1920, 39, 140—145.

The serum obtained by allowing milk to curdle spontaneously in a closed vessel may be used for all the usual serum determinations which serve to detect the presence of added water in the original milk. The only correction necessary is that for the effect of the acidity on the sp. gr.; for each c.c. of N/10 alkali solution required to neutralise 10 c.c. of the serum, 0.00011 is added to the sp. gr. found.—W. P. S.

Milk; Influence of various carbohydrates on the curdling of —. E. Aschenheim and G. Stern. Biochem. Zeits., 1920, 102, 98—124.

MIXTURES of milk with water, oat jellies, or oatmeal extracts were curdled with rennet under conditions resembling those prevailing in the stomach. The mixture with water showed more consistent conditions of coagulation than the oat jelly and oatmeal extract mixtures. The oat jelly mixture produced, however, a curd resembling more the curd formed on curdling human milk than the oatmeal extract mixture. The addition of sugar reduced these differences in coagulation. Lactose influenced this condition in a more pronounced manner than "nutritive" sugar (Nährzucker) and sucrose.—S. S. Z.

Hydrocyanic acid produced by beans; Determination of —. A. Czapski. Z. anal. Chem., 1920, 59, 80.

Less than one-half of the free hydrocyanic acid actually produced is found in the distillate when paraffin wax is added to the distillation flask to prevent excessive frothing of the contents during distillation.—W. P. S.

Proteins; Chemistry of the —. E. Herzfeld and R. Klinger. Biochem. Zeits., 1920, 102, 89—98.

To obtain protein free from adhering impurities, such as the products of protein degradation, fats, lipoids, etc., the clear extract from the tissues is precipitated with 5—6 vols. of 90% alcohol and heated on a boiling-water bath. It is then filtered or centrifuged and the residue is treated with boiling absolute alcohol and again with boiling ether. The protein powder thus obtained is further extracted with boiling water to remove albumoses, peptones, and salts. For the detection and estimation of the higher polypeptides in protein solutions, the protein and the higher polypeptides are precipitated with boiling 90% alcohol, the precipitated fraction is extracted with boiling water; and the nitrogen is estimated in the aqueous extract. Using this method, it was found that all colloidal protein solutions contain appreciable quantities of albumoses. 100 c.c. of human serum contains a quantity of albumoses and peptones equivalent to 0.4 g. of Witte's peptone.—S. S. Z.

Beckmann's process; Nutritive value of straw and chaff hydrolysed by —. Replacement of protein by urea in the diet of growing animals. W. Völtz. Biochem. Zeits., 1920, 102, 151—228.

EXPERIMENTS on a full-grown sheep and three lambs showed that urea could replace the protein in the metabolism of ruminants. The urea is converted in the digestive tract of the animals into bacterial protein, of which 80—90% is eventually absorbed by the system. The requisite carbohydrate for the synthesis of the protein can be supplied by sugar or starch or even to some extent by cellulose. Straw

hydrolysed by Beckmann's process (J., 1919, 384 A) produces a food of higher nutritive value than that obtained by the Lehmann and Colsmann process.—S. S. Z.

Oil-cake; Importance of — as a fodder and, in particular, the value, utilisation, and toxicity of beech nuts. T. Sabalitschka. Ber. deuts. Pharm. Ges., 1920, 30, 259—277.

THE toxic action of beechnut meal is due to the presence of soluble oxalic acid to the extent of 0.51%, probably in the form of potassium hydrogen oxalate, a conclusion which is in full harmony with the physiological symptoms. The poison may be removed by extracting the cake with about five times its weight of cold water during several hours; the residue is still a valuable fodder, but should not be preserved, as it is particularly liable to attack by fungi.—H. W.

Rhubarb juice. J. Angerhausen. Z. Unters. Nahr. Genussm., 1920, 39, 122—130.

ANALYSIS of four samples of rhubarb (stalk) juice are recorded:—Sp. gr., 1.0187—1.0237; total solids, 3.69—4.96; total sugar (as invert sugar), 1.21—2.08; ash, 0.62—0.77; oxalic acid, 0.23—0.32; citric acid, 0.08—0.24; malic acid, 2.0%; free acidity (c.c. N/1 acid), 26.5—29.6. Free oxalic acid is not present in the juice. The free acidity decreases when the juice is fermented, and the whole of the combined oxalic acid may be removed by suitable treatment with calcium carbonate.—W. P. S.

Agar and radium radiation. Fernau. See XVII.

PATENT.

Yeast; Manufacture of foods or stimulants for promoting the growth of — after the yeast has been mixed with other ingredients into the form of dough. W. A. and E. W. Geere. E. P. 143,938, 4.8.17.

A YEAST food consists of a dry mixture of cereal germs which have not previously been heated, cereal meal, starch, ammonium carbonate, and a phosphate.—J. H. L.

XIXB.—WATER PURIFICATION; SANITATION.

Carbon dioxide; Determination of — in moorland waters. V. Rodt. Chem.-Zeit., 1920, 44, 469.

THE presence of free weak organic acids and of their salts in moorland waters interferes with the determination of the free and bicarbonate carbon dioxide. In many cases where the solvent action of the water on limestone is required Heyer's method (Gesundheitsing., 1912, 35, 669) is applicable. The water is shaken at intervals for 3 days in a closed flask with powdered marble, and an aliquot portion then titrated with N/10 acid, with methyl orange as indicator. The results are expressed in mg. CaO per l. The difference between the results of titration of the water before and after the treatment with marble gives the amount of CaCO₃ dissolved. (Cf. J.C.S., Aug.)—C. A. M.

Sewage; Purification of — by activated sludges. R. Cambier. Comptes rend., 1920, 171, 57—60.

THE ferrous sulphide normally present, or artificially introduced, into sludges, appears to be an important factor in the purifying and nitrifying action of these sludges on sewage. It is frequently noticed that when such sludges lose their activity a reddish colour due to ferric hydroxide is apparent. All the causes which tend to destroy the ferrous sulphide or modify its physical state equally tend to destroy the activity of the sludge. It was found that sludges which had become practically inactive

could be re-activated by the addition either of ferrous sulphide or of an equimolecular proportion of solutions of ferrous sulphate and ammonium sulphide.—W. G.

Dichloroethyl sulphide: Toxic action of —. A. Mayer, H. Magne, and L. Plantefol. *Comptes rend.*, 1920, 170, 1625—1628.

DICHLOROETHYL sulphide acts as a general poison. Its action on the various parts of the organism are described.—W. G.

PATENTS.

Germicide and insecticide. L. Cheeseman. U.S.P. 1,313,031, 8.6.20. Appl., 6.3.19.

THE product contains barium hydroxide and hydro-sulphide mixed with another alkaline-earth base.
—J. H. L.

Sewage and other impure liquids; Aeration of —. O. Stott and E. R. Jones. U.S.P. 1,313,797, 15.6.20. Appl., 21.6.19.

SEE E.P. 133,722 of 1918; this J., 1919, 961 A.

Polysulphide solutions [insecticides]; Method of treating —. E. C. Holton, Assr. to Sherwin-Williams Co. Reissue H.890, 22.6.20, of U.S.P. 1,251,908, 29.1.18. Appl., 6.12.19.

SEE J., 1918, 193 A.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Albumins and antitoxins; Behaviour of — towards the electric current and isolation of pure antitoxic albumin from diphtheric serum by the electro-osmotic method. W. G. Rappel. *Ber. deuts. pharm. Ges.*, 1920, 30, 314—328.

PURE antitoxic albumin can be obtained from diphtheric serum by subjecting the latter in a divided cell (the central portion of which contains the serum and is separated from the outer portions which contain the electrodes and pure water by suitable semi-permeable membranes) to the action of an electric current. Electrolytic impurities are thereby first removed, after which euglobulin is precipitated; from the filtered solution the paraglobulin and albumin can be further separated by utilising the fact that the latter is more highly charged than the former, and, in consequence, has a greater rate of migration. The antitoxin is mainly combined with the paraglobulin. (*Cf.* J.C.S., Aug.)—H. W.

Digitalis leaves; Valuation of —. G. Joachimoglu. *Arch. Exp. Path. Pharm.*, 1920, 86, 307—312.

THE potency of extracts from digitalis leaves prepared in various ways was studied. Extraction with absolute alcohol in a Soxhlet apparatus yielded the most potent preparation. By extracting the leaves first with water and then with 50% alcohol the extract had only 60% of the potency of the absolute alcohol extract. Tinctures prepared according to the formula of the German pharmacopœia contained only 75% of the active principle, while tinctures prepared by percolation according to the American pharmacopœia were more active. Chloroform extracted only one-third of the glucoside. Extraction with benzene and subsequent extraction with absolute alcohol yielded 70% of the active principle. Acetone extracted the glucoside extremely slowly. The minimum lethal dose per gram of frog was used as the unit in this investigation.—S. S. Z.

Dulcin (p-phenetoleurea); Alteration in the taste of the sweetening agent — as a result of chemical change. H. Thoms and K. Nettesheim. *Ber. deuts. pharm. Ges.*, 1920, 30, 227—250.

p-PHENETOLEUREA loses its sweetening power when substituents are introduced into the benzene nucleus. (*Cf.* J.C.S., Aug.)—H. W.

p-Hydroxyphenylurea; Sweetening power of derivatives of —. F. Boedecker and R. Rosenbusch. *Ber. deuts. pharm. Ges.*, 1920, 30, 251—258.

ATTEMPTS to obtain a sweetening agent analogous to dulcin (p-phenetoleurea) but possessing greater sweetening power and greater solubility in water were unsuccessful. Hydroxy-p-ethoxyphenylurea, $\text{HO}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{CONH}_2$, m.p. 160°C ., is more soluble in water than dulcin, but is less sweet and has also a bitter after-taste; dihydroxy-p-propoxyphenylurea, $\text{CH}_2(\text{OH})\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{CONH}_2$, m.p. 156°C .— 157°C ., has no sweet taste. (*Cf.* J.C.S., Aug.)—H. W.

Binary solutions; Influence of substitution in the components on the equilibrium in —. AXIII. Binary system antipyrine-benzoic acid. R. Kremann and H. Markl. *Monatsh. Chem.*, 1920, 41, 1—1.

ANTIPYRINE and benzoic acid when melted together form a single equimolecular compound, m.p. 66°C . This compound forms eutectics with antipyrine containing 63.5% of antipyrine at 59.5°C ., and with benzoic acid containing 50.5% of antipyrine at 59.5° .—J. F. S.

Oxalic acid and lactic acid; Detection of — especially their differentiation from tartaric acid. K. Brauer. *Chem.-Zeit.*, 1920, 44, 491.

OXALIC acid gives a bright violet coloration when heated with concentrated sulphuric acid and resorcinol; under similar conditions lactic acid and tartaric acid give red colorations. Heating with resorcinol and dilute sulphuric acid (1:1, or even weaker concentration) serves to distinguish lactic acid from tartaric and oxalic acids; the colorations obtained with this test are:—lactic acid, red; oxalic acid, green; tartaric acid, yellow.—W. P. S.

Nitroform; Estimation of — by potassium permanganate. P. V. McKie. *Chem. Soc. Trans.*, 1920, 117, 646—648.

NITROFORM may be accurately estimated, even in presence of nitric and nitrous acids, by titration with permanganate in acid solution according to the equation: $\text{CH}(\text{NO}_2)_3 + 2\text{O}_2 + \text{H}_2\text{O} = \text{CO}_2 + 3\text{HNO}_3$. The nitroform solution is added to a known excess of N/10 permanganate acidified with sulphuric acid, the mixture is heated to 30°C ., and after remaining 1 min. at that temperature potassium iodide is added and the liberated iodine titrated with thiosulphate. In nitration products the nitrous acid must be destroyed by boiling for about 1 min. with ammonium nitrate, the solution being then cooled to 30°C . and titrated as above. As an alternative the nitroform may be distilled in a current of steam from the product after treatment with ammonium nitrate (30 mins. distillation required) and the distillate titrated.—G. F. M.

Charcoal; Heat of adsorption of vapours on —. A. B. Lamb and A. S. Coolidge. *J. Amer. Chem. Soc.*, 1920, 42, 1146—1170.

THE heat of adsorption of carbon tetrachloride, ether, chloroform, ethyl formate, carbon bisulphide, methyl alcohol, ethyl chloride, ethyl bromide, ethyl iodide, benzene, and ethyl alcohol by charcoal at 0°C . is represented by the equation $h = m\epsilon^n$, where h is the heat of adsorption per normal c.c., ϵ the number of c.c. adsorbed, and m and n characteristic constants. The molecular heats of adsorption are nearly alike in all cases, the extremes being 12.0 cal. (ethyl chloride) and 15.5 cal. (carbon tetrachloride), and the values are the same with charcoals of different adsorptive activity. The net heats of adsorption per c.c. of liquid are practically identical in all cases. Vapours containing halogens appear to react with the charcoal when warmed, so as to decrease the heat evolved by any subsequent adsorption.—J. F. S.

Methyl alcohol; Determination of —. A. Heiduschka and L. Wolf. Pharm. Zentralh., 1920, 61, 361–366.

A SUITABLE quantity of the alcohol is placed in a cylindrical glass bulb of about 150 c.c. capacity, provided with a sealed-in tube reaching to the bottom, and an exit tube; 30% sulphuric acid and an excess of potassium bichromate solution are added, the ends of the two tubes are drawn out to capillaries and sealed, and the bulb is immersed in boiling water for one hour. After cooling the exit tube is connected with a calcium chloride tube and a weighed potash bulb, the capillary point is broken, and the carbon dioxide formed absorbed in the potash bulb. The capillary point on the other tube is broken after connexion with an apparatus supplying a current of air free from carbon dioxide. When all the carbon dioxide has been collected the excess of bichromate is titrated. The amount of methyl alcohol present is calculated either from the weight of carbon dioxide found or the amount of oxygen required for the oxidation. The method may be used for the determination of methyl and ethyl alcohols in mixtures of the same. The acetic acid resulting from the oxidation of the ethyl alcohol is retained by the solution and by the calcium chloride tube during the absorption of the carbon dioxide, and does not enter the potash bulb. Since 0.8% of the ethyl alcohol present is invariably oxidised to carbon dioxide, a corresponding allowance must be made in calculating the quantity of methyl alcohol. The methyl alcohol produced by the hydrolysis of cocaine may be determined by the method.—W. P. S.

PATENT

Dimethylbutadiene; Manufacture of —. Farbenfabr. vorm. F. Bayer und Co. G.P. 319,505, 2.9.16.

PINACONE chlorhydrin is treated with compounds which will combine with hydrochloric acid but do not contain hydroxyl groups, e.g., ammonia or organic bases. A mixture of water and dimethylbutadiene is obtained by distilling a mixture of pinacone chlorhydrin and dimethylaniline between 60° and 80° C.—D. W.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Colloidal silver; Formation of — in photographic developers and means of avoiding it. L. Lobel. Bull. Soc. Franc. Phot., 1920, 7, 21–22.

IN using developing solutions containing sodium sulphite small quantities of silver bromide pass into solution. This occurs, in general, more easily with papers than with plates, since the bromide is in a finer state of division, and more easily with developers having a low content of alkali carbonate in proportion to the sulphite. The dissolved silver salt is reduced by the developer, and part of the reduced silver is deposited on the dishes, etc., and part remains in colloidal solution. Continued use of the developer tends to the production of dichroic fog by deposition of the colloidal silver in the body of the film, and solutions still having considerable developing power may be rendered useless on this account. Ordinary filtering methods will not hold back the colloidal silver. If, however, about 20% of sodium sulphate is added the colloidal silver is coagulated and deposited; its formation is also pre-

vented by the addition of the same salt to a new developer.—B. V. S.

Cyanine dyes. Mills and Wishart. See IV.

XXII.—EXPLOSIVES; MATCHES.

Nitric esters [cordite]; Decomposition of — by lime. T. M. Lowry, K. C. Browning, and J. W. Farmery. Chem. Soc. Trans., 1920, 117, 552–561.

HYDROLYSIS or saponification of the normal type is not the predominant action when cordite is decomposed by lime in the presence of pyridine. Two partly denitrated nitrocelluloses, of approximate formulae $C_{12}H_{18}O_8(NO_3)_2$ and $C_{12}H_{17}O_7(NO_3)_3$, were obtained as by-products of incomplete decomposition, but no cellulose was obtained when the decomposition was carried to completion. Traces of glycerol were detected only when a very large excess of pyridine was used, and these were likewise the only conditions in which a clean crystalline calcium nitrate was obtained. After calcium oxalate, nitrate, and nitrite, the calcium salts of hydroxypropionic acid and dihydroxybutyric acid appeared to be the most important products of decomposition, the former being present in every case where the products were reported to have a toxic action on plants. It is suggested that the main action is a decomposition of the nitric esters into ketones or aldehydes and a nitrite, instead of hydrolysis into an alcohol and nitric acid.

XXIII.—ANALYSIS.

Viscosimeter; Falling sphere —. W. H. Gibson and L. M. Jacobs. Chem. Soc. Trans., 1920, 117, 473–478.

A TUBE 29 cm. long and 2 cm. internal diam. is arranged vertically in a bath provided with a stirrer and thermometer. The tube is divided into three 5 cm. lengths for measurement of the time of fall, and a further 5 cm. above for the sphere to acquire uniform velocity. The sphere is a steel ball, 0.15 cm. diam., as used for ball-bearings, and it is introduced into the viscosimeter tube by means of a short length of glass tubing, 3 mm. diam., fixed by means of a rubber stopper and adjusted to dip 3 cm. below the surface of the liquid. The theory of the falling sphere viscosimeter is briefly discussed, and the following equation expressing viscosity is developed:

$$9\eta S(1+2.4x)(1+3.3r/h)=2gr^2(s-\sigma)T,$$

where T is the time of fall through a length, S, r is the radius and s the density of the sphere, σ the density of the liquid, x the ratio of the radius of the sphere to that of the viscosimeter tube, and h the height of the liquid. This equation reduces itself to $\eta=K(s-\sigma)T$, where K is the numerical constant involving all the corrections for the particular tube. This constant having been found, either by the use of the first equation above, or by experiment with a liquid of known viscosity, determinations for other substances simply resolve themselves into determinations of s, σ and T. For castor oil at 20° C. the value $\eta=9.888$ was found by this method, a figure in close agreement with Kahlbaum and Raber's value.—G. F. M.

Conductometric titrations in neutralisation analysis. III. Titration of combined weak acids or bases in salts. [Displacement curves.] I. M. Kolthoff. Z. anorg. Chem., 1920, 111, 97–108.

The quantity of a weak acid or base combined as a

salt may be estimated by titration with a strong base or acid respectively, using the electrical conductivity as indicator. On adding a strong acid, say hydrochloric acid, to the salt of a weak acid, the conductivity of the solution changes very little until all the weak acid has been liberated, but the first drop of strong acid in excess causes a great increase in the conductivity. On plotting the conductivity against the number of c.c. of standard acid a sharp break will be found, which represents the point of equivalence. The method is found to work well in all cases where after displacement of 50% of the weak acid the conductivity has not increased more than 1%. Examples are given of the titration of sodium acetate and sodium formate, and for weak bases ammonium chloride. In the case of the dibasic acids in sodium oxalate, sodium tartrate, and sodium citrate equally good results may be obtained if in the two last-named cases an equal volume of alcohol is added to the solution before titration.—J. F. S.

Benzoic acid; Reaction of — based on its diazotisation. Application to the toxicological detection of atropine, cocaine and stovaine. M. Guerbet. *Comptes rend.*, 1920, 171, 40—41.

The method consists in nitrating the benzoic acid, reducing the mixed nitrobenzoic acids, diazotising the aminobenzoic acids, and coupling the diazo compounds with β -naphthol to form an orange-red mixture of azo dyes. It is equally applicable to substances such as cocaine or stovaine, which contain a benzoyl group, or atropine, which on oxidation yields benzoic acid. The test may be carried out in a few minutes on a watch-glass with 0.0001 g. of material without isolating or purifying the intermediate products. For toxicological work the test may be applied to extracts of organs prepared by Stas' method. (*Cf.* J.C.S., Aug.)—W. G.

COMPLETE SPECIFICATIONS ACCEPTED.

15,568 (1918). Leamon. Treating gases containing hydrogen sulphide. (120,554.) July 21.

5814 (1919). Macdonald and Macdonald. Making hydrocarbon gas. (146,560.) July 21.

8708 (1919). Naito. See XXIII.
9756 (1919). Olsson. Treatment of peat. (147,286.) July 28.

9768 (1919). Smith. Furnace retorts. (132,487.) July 28.

10,883 (1919). Beswick and Rambush. Destructive distillation of solid fuels. (147,311.) July 28.

18,162 (1919). Wade (Standard Oil Co.). Manufacture of liquid fuel from petroleum. (147,353.) July 28.

20,157 (1919). Skinningrove Iron Co., and Bury. Recovery of products from gases evolved in the destructive distillation of coal, shale, etc. (147,360.) July 28.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Asheroft. 21,728. See II.
Benson. 20,646. See II.

Falk. Manufacture of tar. 20,609. July 10. (Ger., 10.12.17.)

Morgan and others. 21,903. See II.
Seidenschmur. Extraction of paraffin from tar etc. 22,143. July 24.

Sudfeldt u. Co. Obtaining salts of sulpho-acids and alkyl-sulphuric acids from acid resins. 20,584. July 10. (Ger., 14.3.19.)

Sudfeldt u. Co. Obtaining sulpho-acids from brown coal-tar oils. 20,585. July 10. (Ger., 14.3.19.)

Tetralin Ges. 20,353, 20,366, and 20,751. See XX.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Arnot. Azo dyes and process of manufacture. 22,015-6. July 22.

Davies, Thomas, and Scottish Dyes, Ltd. Production of dyestuff intermediates. 22,073. July 23.

Davies, and Scottish Dyes, Ltd. Manufacture of dyestuffs. 22,074. July 23.

Imray (Soc. Chem. Ind. in Basle). Manufacture of azo dyestuffs. 22,090-1, 22,163. July 23 and 24.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Borzykowski. Production of threads. 21,459. July 16. (U.S., 31.4.17.)

Borzykowski. Production of masses or solutions free from air. 21,460. July 16. (U.S., 13.8.17.)

Bouillon and Worms. Filters for producing cellulose threads. 21,633. July 19.

Bouillon and Worms. Treatment of cellulose filaments, threads, or films. 21,634. July 19.

Bouillon and Worms. Apparatus for producing threads from viscose. 21,635. July 19.

Coghlan. Treatment of wool. 21,902. July 21.

Duvinae and Muth. 20,905. See VII.

COMPLETE SPECIFICATIONS ACCEPTED.

8518 (1918). Deuts. Gasglühlicht A.-G. Producing artificial silk. (116,103.) July 28.

14,798 (1919). Portadown Weaving Co., and Greeves. Retting and drying flax and other fibres. (146,702.) July 21.

24,119 (1919). Laan. See XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Farbw. vorm. Meister, Lucius, u. Brüning. Printing with dyestuffs. 21,295. July 14. (Ger., 23.8.16.)

Fish, Gass, Hammond, and Jackson and Bro. Bleaching etc. apparatus. 20,390. July 10.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Azote Française Soc. Anon. Absorbing nitrous vapours. 21,583. July 17. (Switz., 18.7.19.)

Casale. Preparing nitrogen or nitrogen and hydrogen mixtures. 20,706. July 10. (Ital., 12.7.19.)

Chambers, Hammond, and Sowden. Treatment of ferrous chloride liquors resulting from cleansing wire etc. 21,322. July 15.

Chem. Fabr. vorm. Goldenberg, Geromont u. Co., and Wolfenstein. Production of formates of alumina. 21,779. July 20.

Davis and Levy. Absorbent for carbon monoxide. 21,786. July 20.

Duvinae and Muth. Preparing compounds of alumina for sizing paper etc. 20,905. July 12. (Ger., 13.5.19.)

Fiévet. Manufacture of zinc oxide. 21,576. July 17. (Fr., 17.7.19.)

Gepp, Webb, and Williams. Purification of zinc-bearing solutions. 21,499. July 16. (Australia, 17.7.19.)

Griggs. Production of hydrogen. 20,746. July 10.

Janbert. Purification of hydrogen or oxygen. 20,566. July 10. (Fr., 12.10.18.)

Naef. Manufacture of sodium compounds. 21,592. July 10.

Ossa. Cuprous iodide processes. 21,991. July 22.

- Patterson. Substitute for table salt. 21,608. July 19.
 Riedel. Manufacture of compounds of nitrogen. 20,601. July 10. (Ger., 20.11.15.)
 Riedel. 20,603, 20,606-8. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

- 310 (1918). Bailey, Denny, Norris, and Adams. Production of ammonium sulphate. (146,516.) July 21.
 5594 (1918). Harger. Manufacture of hydrogen. (147,235.) July 28.
 8776 (1919). Davies. Extraction of arsenic and other impurities from sulphuric acid. (146,598.) July 21.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

- Beatty, Reeves, and Tucker. Obtaining viscous charges of glass from a viscous mass thereof. 20,556. July 10.
 Hampshire. Glass furnace. 20,917. July 12.
 Llewellyn, Spence, and Spence and Sons. Drying and calcining siliceous substances. 21,111. July 13.
 Rietz. Manufacture of white clouded glasses, enamels, or glazes. 20,654. July 10. (Ger., 19.7.18.)
 Soc. Anon. Verreries de Fauquez. Glass furnaces. 20,451. July 10. (Belg., 9.2.18.)

IX.—BUILDING MATERIALS.

APPLICATION.

- Collyer. Vulcanised wood. 21,376. July 15.

COMPLETE SPECIFICATION ACCEPTED.

- 18,843 (1918). Atkins and Colquhoun. Manufacture of bricks, tiles, clinker, etc. (147,239.) July 28.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

- Amsler. Annealing furnace. 21,018. July 12.
 Bansen, and Façonseisen Walzwerk Mannstedt u. Co. Hearth smelting or annealing furnace. 21,079. July 12. (Ger., 2.12.18.)
 Bardeen and Harris. Restoring strength of steel. 22,066. July 23.
 Chambers, and others. 21,322. *See* VII.
 Coad. Appliances for extracting tin etc. from metalliferous slimes. 21,742. July 20.
 Diehl. Preparation and smelting of ores etc. 20,885. July 12.
 Head, Wrightson and Co., Ringquist, and Wrightson. Means for separating dust from blast furnace gases. 21,797. July 20.
 Heraeus Ges., and Stahlwerke Lindenberg. Manufacture of iron and steel. 20,543. July 10. (Ger., 15.12.17.)
 Huth Ges. Expelling gases from metal bodies etc. 20,996. July 12. (Ger., 21.2.17.)
 Isabellen Hütte Ges. Alloys. 20,473. July 10. (Ger., 4.2.17.)
 Kosugi. Alloys. 21,387. July 15.
 Krupp A.-G. Producing low-carbon ferrochromium. 20,413. July 10. (Ger., 27.7.16.)
 Leiser. Production of alloys. 20,512. July 10. (Ger., 17.8.14.)
 Metallatom Ges. 20,599. *See* I.
 Phoenix A.-G. Smelting iron ores. 20,747. July 10. (Ger., 10.3.16.)
 Simon. Chloridising roasting of burnt pyrites. 21,033. July 12. (Ger., 2.8.17.)

- Wade (Byers Co.). Manufacture of wrought iron. 21,911 and 22,005. July 21 and 22.

COMPLETE SPECIFICATIONS ACCEPTED.

- 2997 (1919). Waring and Waring. Steel-melting plant. (147,244.) July 28.
 11,499 and 15,475 (1919). August. Rotary muffle furnaces. (146,673.) July 21.
 12,186 (1919). Allison (Naigurai Kagaku Seihin Kabushiki Kwaisha). Composition for preventing corrosion of metal surfaces. (146,676.) July 21.
 15,686 (1919). Odani. Production of metallic powders. (129,631.) July 21.
 15,823 (1919). Jacobs. Electrodeposition of metals. (147,338.) July 28.
 3061 (1920). Clarke and Clarke. Composition for preserving metallic surfaces. (146,796.) July 21.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

- Aymard. Continuously renewable cathode or anode surface. 20,755. July 10.
 Aymard. Electrolytic cell. 20,756. July 10.
 Cherry. Apparatus for electro-chemical treatment of vapours. 21,756. July 20.
 Dynamobürsten-Fabr. Nürnberg-Reichelsdorf, and Muth. Production of electric carbons. 20,688. July 10. (Ger., 20.3.18.)
 Grundhofer. Electric induction furnaces. 20,583. July 10. (Ger., 21.1.18.)
 Nolle. Insulating material. 21,655. July 19. (Holland, 19.7.19.)
 Pilkington. Electric furnaces. 20,865. July 12.
 Sieurin. Manufacture of carbon electrodes. 21,051. July 12.
 Sieurin. Burning carbon electrodes in electric furnaces. 21,676. July 19.

COMPLETE SPECIFICATIONS ACCEPTED.

- 5761 (1919). Thompson. Manufacture of carbon electrodes. (147,247.) July 28.
 7179 (1919). Austin and Adkins. Electric cells or batteries. (147,249.) July 28.
 15,823 (1919). Jacobs. *See* X.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

- Byrnes. Separating aldehyde fatty acids from congeneric substances, and manufacture of soaps from these acids. 21,291. July 14.
 Farley. Soap. 21,794. July 20.
 Farley. Grease solvents. 21,795. July 20.
 Mont. 21,949. *See* XIX.

COMPLETE SPECIFICATIONS ACCEPTED.

- 6733 (1919). Sorensen. *See* XIX.
 8757 (1919). Clayton and Nodder. *See* XIX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

- Badische Anilin u. Soda-Fabrik. Manufacture of artificial resins. 21,151. July 13.
 Damard Lacquer Co., Fleet, and Potter. Phenol aldehyde condensation products. 22,078. July 23.
 Wade (Barrett Co.). Manufacture of resin. 21,409. July 15.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

- Feldenheimer, Plowman, and Schidrowitz. Manufacture of rubber. 22,087. July 23.
 Greengate and Irwell Rubber Co. Vulcanising rubber goods. 21,122. July 13.

COMPLETE SPECIFICATION ACCEPTED.

19,132 (1919). Peachey. Process for vulcanising dissolved caoutchouc. (146,734.) July 21.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Chem. Fabr. Worms A.-G. Manufacture of tanning agents. 20,720-1. July 10. (Ger., 17 and 24.8.16.)

Howroyd and Turnbull. Manufacture and use of solutions for tanning. 21,775. July 20.

Stoeckly. Hardening surface of patent leather. 20,469 and 21,704. July 10 and 19. (Ger., 13.4.18, 8.8.19.)

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Benbough. Manufacture of manure. 20,557. July 10. (Ger., 6.3.18.)

British Glues and Chemicals, Ltd., and Kernot. Production of fertilisers. 21,006. July 12.

Riedel. Utilising impure gases containing carbonic acid. 20,922. July 12. (Ger., 24.11.17.)

Riedel. Enriching the atmosphere that envelops plants. 20,923. July 12.

COMPLETE SPECIFICATION ACCEPTED.

12,397 (1919). Hawker, and Hawker and Botwood. Manufacture of a preparation for applying to soil or plants as a fungicide, insecticide, and soil steriliser. (146,678.) July 21.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Martin, Roche, and Tavroges. Manufacture of lactose or milk sugar. 22,019. July 22.

Martin, Roche, and Tavroges. Purification of crude lactose or milk sugar. 22,019. July 22.

COMPLETE SPECIFICATION ACCEPTED.

8741 (1919). Reckitt and Sons, and Hardy. Manufacture of rice starch. (147,255.) July 28.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Bensley. Portable dry yeast. 22,102. July 24.

Plesch. Manufacture of beer. 20,737. July 10. (Ger., 23.8.16.)

Stouffs. Preserving by-products of brewing, distilling, etc. for use as animal foods. 21,673. July 19.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Barrett Co. Manufacture of baking powder. 22,004. July 22. (U.S., 26.4.20.)

Claes. Alimentary substances. 20,449. July 10. (Belg., 15.10.17.)

Martin, Roche and Tavroges. Treatment of whey produced in cheese manufacture. 22,020. July 22.

Maschinenbau A.-G. Balcke. Preventing precipitation from water. 20,542. July 10. (Ger., 25.6.18.)

Mout. Crystallisation of margarine emulsions etc. 21,949. July 22.

Piekee. Manufacture of foodstuffs with calcium chloride as therapeutic mixture. 21,890. July 21.

Stouffs. 21,673. See XVIII.

Strong. Drying fruit, meats, etc. 21,682. July 19.

Thompson. Margarine. 20,779. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

6733 (1919). Sorensen. Manufacture of margarine. (146,567.) July 21.

8757 (1919). Clayton and Nodder. Manufacture of butter substitutes, edible fats, etc. (147,257.) July 28.

12,397 (1919). Hawker and others. See XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Adam and Legg. Production of organic acids. 21,777. July 20.

Byrnes. 21,291. See XII.

Deuts. Erdöl A.-G. 20,715. See II.

Etabl. Poulenc Frères, and Oechsli. Dichlorides of monoarylsarsines. 20,398. July 10.

Henning. Non-inflammable volatile liquid. 21,371. July 15.

Tetralin Ges. Production of tetrahydro- β -naphthol and tetrahydro- β -thionaphthol. 20,353. July 10. (Ger., 18.5.16.)

Tetralin Ges. Production of ar-1-tetrahydro-naphthalenesulphonic acid. 20,336. July 10. (Ger., 25.2.19.)

Tetralin Ges. Production of nitro compounds of tetrahydronaphthalene etc. 20,751. July 10. (Ger., 17.3.16.)

COMPLETE SPECIFICATION ACCEPTED.

15,774 (1919). Marks (U.S. Industrial Alcohol Co.). Methods of forming esters. (147,337.) July 28.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Baker. Photographie films. 21,219. July 14.

Faulstich. Manufacture of multicolour screens for natural-colour photography. 20,910. July 12. (Ger., 27.3.17.)

Ratier. Photographic processes. 20,419. July 10. (Fr., 16.6.19.)

COMPLETE SPECIFICATION ACCEPTED.

25,208 (1919). Natural Color Pictures Co. Colour photography. (143,180.) July 21.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Bash. Matches. 21,425. July 16.

Imray (Soc. Chem. Ind. in Basle). Manufacture of an explosive. 21,293. July 14.

Sprengluft Ges. Blasting-charges. 20,523. July 10. (Ger., 5.1.14.)

COMPLETE SPECIFICATION ACCEPTED.

24,119 (1919). Laan. Stabilisation of nitrocellulose. (147,378.) July 28.

XXIII.—ANALYSIS.

APPLICATIONS.

Arndt. Gas-analysing apparatus. 20,902. July 12. (Ger., 30.11.15.)

Davis. Apparatus for detection and estimation of carbon monoxide. 21,785. July 20.

Davis. 21,786. See VII.

Ubbelohde. Determination of specific weight of gases. 20,579. July 10. (Ger., 7.7.14.)

Union Apparatebau Ges. Testing gas mixtures. 20,586. July 10. (Ger., 24.2.19.)

COMPLETE SPECIFICATION ACCEPTED.

8708 (1919). Naito. Analysing or estimating volatile constituents of coal. (147,254.) July 28.

I.—GENERAL; PLANT; MACHINERY.

PATENTS.

Filter. E. J. Sweetland, Assr. to United Filters Corp. U.S.P. 1,344,215, 26.2.20. Appl., 2.7.13.

AN inclined pipe is interposed between filter leaves contained in a casing, from which a uniform stream of fluid is projected against the face of the leaves and toward the bottom of the casing.—W. H. C.

Filtration membrane; Treating — J. F. Waite. E.P. 141,961, 2.12.19.

IN order to render a colloidal membrane capable of filtering a liquid which is not miscible with the liquid already contained in the membrane, the latter liquid is displaced by a liquid (or liquids used successively) which is miscible with both of the immiscible liquids. For example, a collodion membrane which has been used for filtering an aqueous liquid is treated with 95% alcohol before using it for filtering a coal-tar or petroleum derivative.

—W. H. C.

Filtering apparatus. R. G. y Gonzalez. U.S.P. 1,292,758, 28.1.19. Appl., 12.4.18.

AN outer stationary casing is provided with bearings, which support a hollow shaft carrying a frame composed of discs and rods. A filtering fabric is held in position between the discs, and a flexible fabric of cloth or wire netting is also clamped close to but slightly spaced from the material. The liquid is supplied to the hollow shaft, and thence through openings into the filter body, where it is filtered by centrifugal force. By displacing the filter body along the shaft the fabric becomes folded or collapsed, and the adhering solid matter is detached into a compartment at the bottom of the casing.—W. F. F.

Drying drum with sectorial compartments. J. Janka. G.P. 320,526, 8.9.18.

DRUMS arranged horizontally in a drying chamber and divided into sectorial compartments for containing the material, are filled and emptied at the top, and the speed of rotation of the drums is regulated by the difference in weight between the freshly added and the dried material, so that the material is dried in a single revolution.—L. A. C.

Drying plant. P. Barducci. U.S.P. 1,311,163, 22.6.20. Appl., 22.3.19.

A CASING containing a ventilator is reciprocated between the longitudinal shelves on which the material to be dried is supported within a chamber, so as to produce a draught and a blast of air simultaneously between the supports.—W. H. C.

Dryer; Rotary — W. M. Schwartz, Assr. to The Philadelphia Textile Machinery Co. U.S.P. 1,345,620, 29.6.20. Appl., 22.1.20.

A ROTARY drying cylinder is lined with two series of longitudinal trough-shaped blades, one set having inwardly and the other outwardly projecting edges which overlap.—B. M. V.

Solvents; Apparatus for reclaiming — P. Gerli and O. A. Ross. U.S.P. 1,315,083, 29.6.20. Appl., 4.5.18.

A MATERIAL in the form of a long strip which is to be treated with solvent is passed over rollers in a hermetically sealed chamber and is wound from one roller on to another. The speed of the winding roller is varied in accordance with its diameter, so that all parts of the material are exposed to the solvent for the same time. The solvent is evaporated from the strip into the chamber, and the vapour is exhausted and then condensed.—W. F. F.

Reverberatory furnace for use with liquid fuel. L. C. Strub. G.P. 319,379, 6.10.18.

THE flue in which combustion takes place is arranged longitudinally below the middle of the hearth and opens out into a space behind it, from which the hot gases are drawn to both sides of and over the hearth towards the front, whence they pass through openings at each side into flues which lie on either side of the combustion flue and open into the common stack.—A. R. P.

Heating furnace. (A, B) W. C. Buell, Assr. to Tate-Jones and Co., Inc. U.S.P. 1,311,136-7, 22.6.20. Appl., 21.3.18, 8.4.18. (C) W. C. Buell and J. W. Griswold, Assrs. to H. L. Doherty and Co. U.S.P. 1,311,438, 22.6.20. Appl., 21.4.18.

THE waste gases are led through the side walls of the furnace near the bottom, then upwards. Recuperators are provided surrounding the upward conduits (A, B) or elsewhere (C), and may be simple counter-current jackets (A) or of the multiple-pass type (B), and in (C) mechanical means may be provided for forcing the air to burners and exhausting the waste gases.—B. M. V.

Purification of air or other gases. W. J. Mellersh-Jackson. From B. F. Everitt. E.P. 145,344, 20.11.19.

CLEAN air is drawn sideways or backwards from a stream of dirty air which has been propelled against the convex face of a concavo-convex deflector (or other means of producing a Venturi effect), whereby the speed of the air and dirt is increased to such an extent that the dirt is carried past the opening for clean air.—B. M. V.

Gases; Apparatus for cleaning — G. W. Hewitt and A. Steinbart. U.S.P. 1,344,585, 22.6.20. Appl., 8.9.19.

GAS passes into a vertical cylindrical chamber at the top through a tangential inlet, and the solid impurities are separated centrifugally during its downward passage to a central outlet conduit. The solid matter separates into a number of collecting receptacles at the bottom formed by concentric cylindrical partitions, each receptacle being closed at the bottom and provided with a controllable outlet. The partitions extend upwards to different heights above the lower end of the outlet conduit.

—W. F. F.

Orifice-precipitator. L. Bradley, Assr. to Research Corp. U.S.P. 1,344,330, 22.6.20. Appl., 31.10.18.

A NUMBER of plates are fixed vertically, parallel to one another, within the precipitating chamber. Each plate has an orifice which is offset laterally with respect to the orifice in the adjacent plates and through which a rod attached to the opposite plate projects.—W. H. C.

Cooling and crystallising hot solutions; Apparatus for — Maschinenbau-A.-G. Balcke. G.P. 319,968, 10.8.18.

A SERIES of endless bands circulates through the solution, so that, while the lower part of each band is immersed, the upper part, to which the liquid adheres, or by which it is taken up by means of special apparatus attached, is subjected to a current of cold air.—A. R. P.

Solutions; Making and transporting — F. W. Thorold. U.S.P. 1,344,102, 22.6.20. Appl., 29.5.18.

A SOLVENT is forced under pressure through a measured quantity of the material to be dissolved, and the pressure is utilised to force the solution into a receptacle. The flow of solvent is so adjusted that the whole of the material is dissolved when the receiver is filled to a predetermined level.

—W. H. C.

Mixing and/or agitating machines. Brinjes and Goodwin, Ltd., and H. P. Harris. E.P. 145,230, 23.5.19.

A HEMISPHERICAL pan supported on trunnions is provided with a double stirrer that enters the pan at an angle so that the pan can be tilted for pouring without disturbing the stirring gear. The stirrer consists of two elements revolving in opposite directions; a sleeve shaft rotates a circular hoop which almost scrapes the interior of the pan, and a concentric solid shaft carries stirring blades rotating in the opposite direction to and within the hoop.—B. M. V.

Grinding or pulverising ore or other material; Mills or machines for —. R. Hush. E.P. 145,159, 26.3.19.

A disc grinder is fitted with various mechanical improvements, among which are a ball and socket joint connecting the door to the fixed disc, adjustable bearings for the shaft, and an unequal number of corrugations on each disc.—B. M. V.

Pulveriser mill. J. W. Fuller, Assignor to Fuller-Lehigh Co. U.S.P. 1,345,082, 29.6.20. Appl., 1.6.18.

MATERIAL is ground in a horizontal ball mill and then carried upward by a current of air into a cylindrical settling chamber. Another chamber having the same diameter is arranged above the settling chamber and contains a fan for maintaining the upward draught of air. The pulverised material is finally carried outwards from the superposed chamber to the discharge.—W. F. F.

Deflocculating solid materials and agents therefor. E. G. Acheson. U.S.P. 1,345,305, 29.6.20. Appl., 22.1.20.

A DEFLOCCULATING compound is made by the reaction of hexamethylenetetramine upon the heat-conversion products of starchy materials.—B. M. V.

Deflocculating solid substances [graphite]; Method of —. E. G. Acheson. U.S.P. 1,345,306, 29.6.20. Appl., 1.5.20.

GRAPHITE is mixed to a paste with a deflocculating agent and moisture (up to 32% of the latter) and subjected to attrition.—B. M. V.

Drying goods in layers; Apparatus for —. A. Hofmann. U.S.P. 1,344,893, 29.6.20. Appl., 31.10.18.

SEE E.P. 123,923 of 1918; J., 1919, 275 A.

Refrigerating apparatus; Ammonia-dissolving composition for use in —. C. Delaygue. U.S.P. 1,345,144, 29.6.20. Appl., 16.2.20.

SEE E.P. 140,353 of 1913; J., 1920, 355 A.

Straining or filtering apparatus. F. C. Fulcher. E.P. 145,339, 13.11.19.

Decanting and agitating apparatus. E. S. Pettis. E.P. 145,389, 13.3.20.

Furnaces; Recuperators or regenerators for —. A. B. Chantaine. E.P. 18,472, 8.8.14. Conv., 29.8.13.

Heat-transference between gases, vapours, or liquids; Appliances for effecting —. W. Y. Lewis. E.P. 145,109, 12.3.19.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Hydrocarbon motor fuels. G. Baume, P. Niclardot, P. E. Erckmann, and H. Vigneron. Chim. et Ind., 1920, 3, 761—768.

THE minimum temperature at which a definite homogeneous mixture of hydrocarbon, alcohol, and benzene (or ether) can exist rises very rapidly with

increase in water content of the alcohol. The solubility of polymethylene hydrocarbons in alcohol (95 and 90%) at a given temperature is greater than that of the aliphatic hydrocarbons, with the exception of hexamethylene, which has a high m.p. (+5° C.). This exception is eliminated by the addition of benzene to the solvent. The solubility of an alcohol of a given strength at a definite temperature in a hydrocarbon decreases with the rise in the position of the hydrocarbon in its series, whilst the lighter a hydrocarbon the greater is its solubility in alcohol. At 0° C. heptane and absolute alcohol are miscible in all proportions; 95% alcohol at that temperature dissolves up to 30% and 90% alcohol up to 17% of heptane. All mixtures of benzene and alcohol containing over 50% of the former solidify above 0° C. The volume of benzene to be added to a system of hydrocarbon and alcohol to obtain a homogeneous mixture increases with decrease in the volatility of the hydrocarbon; a mixture of 33% of ordinary petrol with 67% of 95% alcohol required the addition of 15% of benzene at -5° C., whereas when the petrol was replaced by a very light petroleum spirit only 1.5% of benzene was required.—C. A. M.

Thiocyanates; Determination of — in ammoniacal liquor and waste liquor from ammonia stills in the by-product coking industry. J. A. Shaw. J. Ind. Eng. Chem., 1920, 12, 676—677.

To 500 c.c. of the liquor are added 5 g. of ferrous sulphate and 100 c.c. of 10% sodium hydroxide solution; after 18 hrs. the mixture is filtered, the insoluble portion washed with 3% sodium hydroxide solution, the filtrate heated to 60° C., acidified with sulphuric acid, and treated with 10% ferric chloride solution. The precipitate (Prussian blue, sludge, etc.) is filtered off, the filtrate diluted to a definite volume, and an aliquot portion heated to 70° C. with the successive addition of dilute sulphuric acid, an excess of sodium bisulphite, and hot 10% copper sulphate solution. The cuprous thiocyanate is collected, oxidised with bromine in alkaline solution, the solution then acidified with hydrochloric acid, evaporated, the residue dissolved in hot dilute hydrochloric acid, the solution filtered to remove silica, and the sulphuric acid in the filtrate precipitated as barium sulphate. This quantity of sulphuric acid is equivalent to the amount of thiocyanate in the original liquor.—W. P. S.

Petroleum; Origin of —. Formation of petroleum from free fatty acids or soaps. Formation from animal hydrocarbons. A. Grün and T. Wirth. Ber., 1920, 53, 1301—1312.

The experiments of Pictet and Potok (J., 1919, 939 A) have been repeated with very different results. The main products of the distillation of sodium stearate *in vacuo* are unsaturated liquid hydrocarbons and pentatriacontanone, the latter of which is practically completely decomposed when the distillates are fractionated at the ordinary pressure. The recent isolation of hydrocarbons by Mastbaum, Tsujimoto, and Chapman from the liver oils of certain fish suggests another possible origin of petroleum (cf. J.C.S., Sept.).—H. W.

Oil emulsions; Separation and examination of —. K. Glaser. Feuerungstech., 1920, 18, 149—153.

A TYPICAL sample of brine from a Boryslaw crude petroleum emulsion was found to contain 13% of sodium chloride with smaller amounts of calcium, magnesium, and bromine. The separation of emulsions can be effected more or less readily by heating to about 80° C., by standing, or by increasing the difference in specific gravity of the two components, e.g., by adding some water-soluble substance or by diluting the oil with benzene. Heating under a pressure of 2—3 atm. has been employed with satisfactory results. Filtration alone is of little value, but

centrifuging is effective, as also is the Cottrell method of agglomerating the water droplets in a high-tension electrostatic field. On a commercial scale it is customary to allow as much water as possible to separate spontaneously and to pass the oil through preheaters heated by flue gases or hot distillate, whereby the water and light petroleum oil are vaporised. This water contains fatty acids, phenols, and sulphurous acid. Emulsified lubricating oil from a steam engine is best dehydrated by heating, when part of the water separates, and filtering the hot oil through a filtering medium previously wetted with oil. For the estimation of the water content of emulsions the oil may be diluted with petroleum spirit in a graduated tube and the volume of separated water read off directly, or the oil may be heated in a current of dried air and the water trapped in a cooled receiver and finally in a calcium chloride tube. Direct measurement of the water thrown out by centrifuging is sometimes adopted, or the oil may be mixed with xylene and distilled, the water in the distillate being collected and measured. Among chemical methods of estimation the best consists in exposing the wet oil to calcium carbide and measuring the acetylene evolved. A similar method based on the use of metallic sodium does not appear to be very satisfactory.—A. E. D.

Oil shale; Utilisation of —. G. Grube. *Z. angew. Chem.*, 1920, 33, 181—182.

WÜRTEMBERG oil shales yield on distillation 6—7% of oil (or 10—11% if a special process is used), with about 1% of sulphur as a by-product. The shales yield about 30% of gas in the ordinary retorts at 1100°—1300° C., and the residual slag forms a heat-insulating and weather-resisting building material. The carbon dioxide in the gas derived from the calcium carbonate is converted into carbon monoxide by passing the gas over red-hot coke. One kg. of shale yields 0.128 cb. m. of gas of 4200 cals. per cb. m.—C. A. M.

Petroleum spirit; Estimation of aromatic hydrocarbons in —. W. Hess. *Z. angew. Chem.*, 1920, 33, 176.

To avoid loss by evaporation in measuring the petroleum spirit (*cf.* J., 1920, 509 A) a 60 c.c. pipette is employed having a long tip which is allowed to touch the bottom of the flask. Nitric acid (sp. gr. 1.42) intended for use in the nitration acid is freed from nitrous oxides by air-blowing at 40°—45° C. In estimating the un-nitrated hydrocarbons a temperature correction for the volume of the petroleum spirit is necessary if the reading is made immediately after nitration.—W. J. W.

Pyrogenic acetylene condensations. I. I. R. Meyer and K. Taeger. *Ber.*, 1920, 53, 1261—1265.

THE mixture of picrates obtained from the fractions of higher boiling point derived from the acetylene tar described previously (J., 1919, 35 A) is shown to contain fluorene, acenaphthene, anthracene, phenanthrene, pyrene, small quantities of fluoranthene, and a hydrocarbon, $C_{17}H_{14}$, m.p. 186° C., which yields a picrate, m.p. 231° C.—H. W.

Tar from coal. Fischer and Schrader. *See* III.

Sulphur in fuel. Vita. *See* X.

PATENTS.

[*Fuel.*] *Drying the pressed residues obtained from the hydrolysis of starchy mosses; Process for* —. V. H. Frestadius. G.P. 320,375, 12.2.18.

RESIDUAL sugar is removed from the material by fermentation or repeated washing with water so that it may be readily dried for use as fuel.

—L. A. C.

Fuel for explosion motors. Hlasehkowerko Eberhard und Jacob. G.P. 319,893, 10.4.18.

THE fuel consists of a mixture of 80 parts or less of coal-tar hydrocarbons of sp. gr. 0.8—0.9 with 20 parts or more of fatty (acetic) acid esters.—L. A. C.

Peat, crude cellulose, oil seeds, grain, or the like; Process for disintegrating and extracting liquid from moist —. B. Melzer. G.P. 320,856, 29.12.17.

THE material is disintegrated between revolving compressors, and the liquid content is taken up by a layer of absorbent material from which it is subsequently expressed.—L. A. C.

Gas; Process for making —. D. E. Campbell. E.P. 141,868, 29.5.19.

LIQUID hydrocarbon or mineral oil such as a petroleum distillate of about 48° B. (sp. gr. 0.786) is converted into a permanent gas by subjecting a jet to violent concussion against a hard surface. The jet is ejected from a nozzle of about 0.01 sq. in. in area under a pressure of 9 to 10 atm. against a small transverse metal plate placed in a conduit through which a current of air is flowing. The oil is thereby converted into a stable gas and mixed with air, and the mixture is suitable for heating, lighting, or power purposes.—W. F. F.

Producer gas generated within retort setting or retort; Process for enrichment of —. C. Griffin. E.P. 141,989, 15.4.20.

TAR is injected by means of steam into one or more retorts in a setting, and the resulting gas is mixed with the producer gas in the ascension pipe or hydraulic main.—W. F. F.

Furnace retorts. C. H. Smith. E.P. 126,614, 17.4.19. *Conv.*, 9.5.18.

A HORIZONTAL furnace retort for the partial carbonisation of coal is of inverted heart shape in cross section, and is heated by two sets of combustion flues separated by longitudinal flues and controlled independently. The two sets of flues are symmetrical with respect to the separating partition in the longitudinal vertical axis of the retort. Each heating flue is independently supplied with gas, and with air from a recuperator, the gas and air supply valves being regulated from a longitudinal tunnel below the retort bounded on either side by the recuperators. The waste gas from both sets of flues passes through a common collecting flue to the recuperators. The retort is provided with a pair of parallel rotary conveyors, one in each side of the heart-shaped section. The blades of the two conveyors rotate in paths which intersect, and the shafts of the conveyors are adjustable both horizontally and vertically to vary the position of the blades.—W. F. F.

Illuminating gas and tar; Manufacture of —. H. Geyer. G.P. 319,521, 6.5.19. *Addn.* to 317,977.

FINELY-GROUND coke dust is mixed with the coal dust before it is charged into the retort and treated as described in the chief patent (J., 1920, 395 A) to prevent the tar adhering to the balls and to ensure better contact with the gas stream.—L. A. C.

Gas producers. W. Antrobus. E.P. 145,161, 29.3.19.

LOW-GRADE fuel such as wood, peat, Kimmeridge and oil shales, and inferior coal is fed into a storage chamber at the top of the producer, where it is dried and preheated. The fuel then passes downwards through a number of vertical cast-iron tubes of 12 to 24 in. diameter to the lower part of the producer, where it is heated by the hot gas rising from the combustion zone below. The rich gas generated in this zone is drawn off through an

outlet immediately below the vertical tubes. The producer gas generated in the combustion zone passes upwards through small vertical tubes depending from the larger tubes into the combustion zone, and then upwards through these tubes to an outlet at the top of the producer. The central portion of the producer tapers outwards and the lower part tapers inwards and is provided with two constricted sections. The producer is suitable for the production of by-products such as ammonia and tar.—W. F. F.

Gas producers. J. Harger. E.P. 145,136. 22.3.19.

COAL is introduced into the top of a vertical producer which is provided with two side openings opposite to one another near the bottom, in each of which a regenerator is fitted. The regenerators are connected with a heat exchanger in such a way that either may be connected with the tubes or with the space surrounding the tubes. When a mixture of air and steam or carbon dioxide is blown through the heat interchanger and one regenerator into the producer, producer gas is generated and removed through the other regenerator and the recuperator to heat the incoming air. Water-gas may be generated by first blowing air through in one direction to heat the fuel and then blowing steam through in the opposite direction. During the next cycle the air and steam are blown through in the opposite directions. Some coal gas may be extracted at the top, and the distillation is effected without cracking the gas.—W. F. F.

Hydrocarbons; Apparatus for cracking and distilling —. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,345,132-4, 29.6.20. Appl., 22.3.17 and 29.9.17.

(A) A LIQUID-PHASE horizontal cracking still is arranged so that the vapours are continuously drawn off through a condenser and the uncondensed gases returned through a compressor to the bottom of the still in order to effect agitation and prevent coke formation at the heating surface. (B) A false bottom is fitted to the still in (A) to serve as a coke trap. The contents of the still are continuously circulated by the injected gases so that they pass through this coke trap and deposit suspended coke. (C) The still is heated by a bath of fusible metal which is also circulated by a pump into the oil and back into the main bath of metal.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Distilling carbonaceous material; Apparatus for —. W. P. Perry. E.P. (A) 145,101 and (B) 145,102, 20.1.19.

(A) PEAT, shale, or the like is fed through a gas-tight valve into one chamber of a producer divided by a vertical partition, and is subjected to a gradually increasing temperature and distilled during its downward passage. The partition extends downwards to a level at which all the carbon dioxide has been converted into monoxide. The hot gas passes upwards into the other chamber, and thence into the fuel chamber through openings inclined downwards to prevent passage of solid material in the opposite direction. The distillation is effected by the hot gases. The gas passes out through openings in the wall of the fuel chamber to a main and thence to a condenser. (B) The apparatus is of similar construction to that described in (A) except that the partition extends the full length of the producer. A fire is maintained in the bottom of the empty chamber to generate gas, which then passes into the producer chamber to distil the material.—W. F. F.

Heat; Method of producing —. C. E. Lucke. U.S.P. 1,344,049, 22.6.20. Appl., 11.9.15.

AN explosive gaseous mixture is projected, with an initial velocity greater than that of flame propagation, in a rapidly expanding free jet. The mixture is burned at the point at which its velocity is reduced to that of flame propagation.—W. F. F.

Mercury arc lamp. W. C. Heraeus G.m.b.H. G.P. 318,836, 31.12.18.

A MERCURY arc lamp has a tungsten anode placed at such a distance from the mercury as to maintain permanency of the arc even at high pressures and with great resistance. In this lamp a five- to tenfold increase in brightness corresponds to a ten- to twenty-fold increase in the ultra-violet radiation in the neighbourhood of 366 μ , and there is smaller consumption of energy and a more permanent length of arc than with carbon arc lamps.

—W. J. W.

Heating furnace. U.S.P. 1,344,436-7. See I.

III.—TAR AND TAR PRODUCTS.

Tar from coal; Determination of the yield of —. F. Fischer and H. Schrader. Z. angew. Chem., 1920, 33, 172-174.

THE apparatus consists of an aluminium retort, the interior walls of which slope towards the base to facilitate removal of residue, and having a close-

fitting lid. On one side of the retort is a nose-shaped extension with central bore, into which is screwed a brass tube through which the tar distils into a glass receiver immersed in water. A thermometer is inserted into a semi-circular expansion of the retort wall. For the estimation 20 g. of coal is heated to 500°–520° C. within 30 mins., the temperature being maintained for a further 15 mins. The distillate is then weighed, after which the water constituent is distilled off with xylol or centrifuged, the residual tar being again weighed. Results obtained with several varieties of coal are tabulated.—W. J. W.

Oxylation of benzene. [Preparation of nitrophenols.] L. Vignon. Bull. Soc. Chim., 1920, 27, 547–550.

To obtain the best yield of nitrophenols by the action of nitric acid and mercuric nitrate on benzene it is advisable to use an excess of benzene; the proportions recommended are 1000 g. of nitric acid (sp. gr. 1.3–1.33), 25 g. of mercuric nitrate, and 500 g. of benzene, the mixture being heated in a water bath for 5–7 hrs. For each 100 g. of benzene utilised in the process 230–250 g. of a mixture of nitrophenols of m.p. 75°–80° C. is obtained; the nitrogen content indicates that it is a mixture of about 52% of dinitrophenol and 48% of picric acid.—W. G.

Phenol and certain of its homologues; Diazometric determination of —. R. M. Chapin. J. Ind. Eng. Chem., 1920, 12, 568–571.

The phenol is titrated with a diazonium salt solution. The latter is prepared by dissolving 14 g. of *p*-nitraniline in 400 c.c. of water and 70 c.c. of concentrated nitric acid, filtering the solution after 18 hrs., and diluting it to 1 litre; 5 mins. before use a portion of this solution is mixed with an equal volume of 1% sodium nitrite solution. It is standardised against *N*/10 β -naphthol solution (cf. Bucherer, J., 1907, 818). For the determination 20 c.c. of approximately *N*/10 phenol solution is mixed with 50 c.c. of 10% neutral sodium acetate solution and 10 c.c. of 30% basic lead acetate solution, and the diazo solution is run in from a burette, with constant stirring; as each 10 c.c. of diazo solution is added a further quantity of 10 c.c. of basic lead acetate solution is introduced. When the end of the titration is near the stirring is interrupted for 20 mins. and two small filtered portions of the mixture are then tested, one with a drop of the diazo solution and the other with a drop of phenol solution. If no colour develops in either within a few seconds, a drop of 25% sodium hydroxide solution is added to each; the distinction is sharp when the end-point is at some distance on either side, but if it is near a coloration may develop in both tests. The limits coarsely defined in this first titration may be narrowed down by subsequent titrations. Trustworthy results are obtained in the case of phenol, cresols, and xlenols, but the figures for thymol are much too high. (Cf. Fox and Gauge, J., 1920, 260 r.)—W. P. S.

Furfuraldehyde and phenols. Beckmann and Dehn. See XIII.

Nitro compounds. Van Duin. See XXIII.

Nitro-groups. Desvergues. See XXIII.

PATENTS.

Tar; Apparatus for the continuous distillation of —. G. Romberg. G.P. 321,293, 5.7.17.

A VESSEL for the continuous distillation of tar is provided with inclined, zig-zag, or spiral-shaped plates attached to the bottom so that the tar is in constant motion during the process. Local overheating of the tar is thus prevented, better frac-

tation is attained, and the residue is readily removed from the apparatus.—L. A. C.

Benzol and its homologues; Process of purifying —. Phoenix A.-G. für Bergbau und Hüttenbetrieb. G.P. 299,073, 14.12.15.

SUFFICIENT alkali or alkaline-earth, solid or in concentrated solution, is added to neutralise the acid in the mixture obtained after treating crude benzol or the like with sulphuric acid, so that after distillation of both layers together a water-soluble residue, suitable for use in keeping machine tools cool, is obtained without production of waste water. The two layers may be distilled separately, in which case a material suitable for use as a substitute for resin is obtained from the lower layer.—L. A. C.

Carbon bisulphide; Extraction and recovery of —. H. G. Colman and E. W. Yeoman. E.P. 145,099, 20.12.18.

CARBON bisulphide may be readily extracted from liquids containing it (e.g., benzol) by agitation with a cold aqueous solution of an alkali or alkaline-earth bisulphide, whereby a salt of perthiocarbonic acid, H_2CS_3 , is formed. The perthiocarbonate may be used as a bactericide or decomposed by acids to produce carbon bisulphide, hydrogen sulphide, and sulphur; the first of these is steamed off and condensed, the second absorbed in hydrated ferric oxide, and the sulphur recovered by filtration and used in the preparation of more bisulphide solution. If iron salts or ferric hydroxide are employed instead of acid a precipitate of ferrous sulphide and sulphur is obtained which on exposure to the air oxidises to ferric oxide and sulphur. Simple distillation of the perthiocarbonate solution gives a distillate of carbon bisulphide and hydrogen sulphide and a residue of polysulphide and hydroxide which can be converted into bisulphide again. The escaping gases which contain carbon bisulphide may be stripped by a preliminary purification with hydrated ferric oxide and lime and subsequent passage through alkali-cellulose, thus forming cellulose xanthate.—A. E. D.

IV.—COLOURING MATTERS AND DYES.

Dyes; Fission of organic — by hydrogenation. R. Meyer. Ber., 1920, 53, 1265–1276.

ALIZARIN Direct Violet R and Alizarin Direct Green G (M. L. and B.) are decomposed by hydriodic acid with the formation of leucoquinizarin and *p*-toluidine-2-sulphonic acid and are thus isomeric with Alizarin Irisol and Alizarin Cyanine Green G (Bayer), which give leucoquinizarin and *p*-toluidine-3-sulphonic acid. The utility of hydriodic acid in effecting the fission of azo-dyes has been investigated; in general, an aqueous or alcoholic solution of the dye is heated with an excess of concentrated hydriodic acid until action appears to be complete. The liberated iodine is removed by sulphurous acid and the hydriodic acid by evaporation with hydrochloric acid. The method has the advantage over other reduction processes that it does not introduce any inorganic salts into the solution. Satisfactory results have been obtained with Methyl Orange, Diphenylamine Orange, Metanil Yellow, Congo Red, and Naphthylene Red.—H. W.

3.6-Tetramethyldiaminoselenopyronine. M. Battagay and G. Hugel. Bull. Soc. Chim., 1920, 27, 557–560.

A MIXTURE of sodium selenite and sulphuric acid

monohydrate is added gradually to sulphuric acid containing 25% of sulphur trioxide, and at the same time tetramethyldiaminodiphenylmethane is added in small portions so that it is always present in slight excess, the temperature not being allowed to rise above 35°. After 1½ hrs. the mixture is poured on to ice, filtered, and zinc chloride solution (sp. gr. 1.6) added to the filtrate. A crystalline precipitate of tetramethyldiaminoselenopyrroline zinc chloride, $C_{12}H_{12}N_2SeCl_2 \cdot ZnCl_2$, is obtained. It dissolves in sulphuric acid to a red solution, which turns blue on dilution, and on the addition of sodium hydroxide a reddish-blue base is precipitated, which is soluble in ether. It dyes tannin-mordanted cotton deep violet-red shades from aqueous solution.—W. G.

Colouring matters of flowers. Kögel. See XXI.

PATENT.

Dyestuffs and their intermediates; Process for purifying organic —. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 320,149, 31.7.14.

EITHER basic or acid electrolytes, which act respectively as electro-negative and electro-positive colloids, are added to dyes (or their intermediates), whereby the dyes are converted to the colloidal state, and impurities are then removed by an electric current. An example is given of the purification of an anthracene dyestuff of unknown composition, and insoluble in water, acids, and alkalis, by means of sodium silicate solution.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Silk; Relation between the internal complex metallic salts and the solubility of — in ammoniacal nickel solutions. The biuret reaction (Cu, Ni, Co) of silk and wool. M. Battagay and T. Voltz. Bull. Soc. Chim., 1920, 27, 536—540.

THE colour changes and the ultimate solution of silk when it is immersed in an ammoniacal nickel solution are explained on the basis of the formation of a complex nickel salt with a cyclic structure. The action is thought to be similar to the biuret reaction, which is found to be obtained under suitable conditions with alkaline copper and cobalt solutions, the former giving a violet and the latter a pink tint on silk. Allowing for the sulphur present in wool, similar results are obtained with it or with the products of its partial hydrolysis by acid.—W. G.

PATENTS.

Typhacæ; Process for treating — to obtain fibrous material and a by-product. P. Höring. G.P. 303,933, 2.11.17.

REEDS such as *Typhacæ*, before treatment with liquor to separate the fibrous matter, are boiled exhaustively with water, and, after removal of the undissolved residue, the aqueous solution is evaporated to dryness under reduced pressure. A yellowish brown, hygroscopic product is obtained which contains 20% of ash, chiefly calcium and phosphoric acid, nitrogenous matter, and hexoses and pentoses, and possesses nutrient and therapeutic properties.—L. A. C.

Scouring fibres of vegetable origin; Process for — with the object of accelerating and facilitating subsequent bleaching. E. T. J. Watremez. E.P. 135,516, 21.11.19. Conv., 8.11.18.

THE scouring bath contains soluble alkali-metal compounds obtained by treating a metallic oxide or

preferably a powdered metal with an alkali, an alkali hypochlorite, and a reducing agent, and may be prepared thus: 5 kg. of zinc dust is stirred into a solution of 25 kg. of sodium "hyposulphite" in 50 l. of commercial sodium hypochlorite solution, allowed to stand 12 hrs., 150 l. of caustic soda of 30° B. (sp. gr. 1.262) is added, and the liquor decanted after standing 24 hrs. Vegetable fibres are boiled in this solution (suitably diluted) for 4—6 hrs., 15 kg. of slaked lime is added, the fibres are further boiled for 3—4 hrs., immersed for 2—3 hrs. in a solution of ammonium sulphate (5—7% by volume), rinsed, immersed for 2—4 hrs. in a cold acid bath containing 2% by volume of sulphuric acid of 60° B. (sp. gr. 1.712), and rinsed; they are then ready for bleaching by ordinary methods. The treatment may also be carried out in the cold.—A. J. H.

Washing and cleaning; Process of —. M. Buchner. G.P. 319,933, 24.8.16. Addn. to 312,220 (J., 1919, 714 A).

COLLOIDAL magnesium hydroxide, prepared by treating a solution of a magnesium salt, of which the acid radicle does not form an insoluble calcium salt, e.g., magnesium chloride, with milk of lime at 70°—100° C., is used for washing and cleaning all kinds of materials.—L. A. C.

Wood-pulp liquor; Method of refining crude —. P. Hein, Assr. to The Chemical Foundation. U.S.P. 1,344,691, 29.6.20. Appl., 24.10.16.

CRUDE wood-pulp liquor is refined by mixing it with wood ashes.—A. J. H.

Sulphite waste liquor; Obtaining [resinous] products from —. W. Oehl. G.P. 320,508, 30.11.16.

SILICATES or compounds of heavy metals are added to sulphite waste liquor, whereby the calcium bisulphite is converted into calcium silicate or into an insoluble bisulphite, which is then separated from the resin solution.—L. A. C.

Plastic, gummy material from cellulose esters; Manufacture of —. F. Clouth. G.P. 319,723, 6.12.17.

A PLASTIC, gummy material contains a cellulose ester, such as cellulose acetate and anthracene oil, with or without the admixture of a substance which forms a homogeneous mixture with anthracene oil, such as triphenyl phosphate, sulphanilide, triacetin, or ethyl lactate. Anthracene oil increases the elasticity and waterproof qualities of the product.—L. A. C.

Celluloid, vulcanite or the like; Production of substitutes for —. W. T. Robinson-Bindley, A. W. Weller, and E. Dulcken. E.P. 145,128, 21.3.19. Addn. to E.P. 134,564 (J., 1920, 14 A).

IN the production of synthetic resins from cresol and formaldehyde, the sodium sulphite used as catalyst may be replaced by an inorganic fixed base as sodium or potassium hydroxide, or by an alkali salt as sodium carbonate, acetate, or formate.—A. J. H.

Retting fibrous substances; Process of —. E. L. Rinman. U.S.P. 1,344,719, 29.6.20. Appl., 2.10.18. See E.P. 128,464 of 1918; J., 1919, 678 A.

Ramie, flax, hemp, and like plants; [Mechanical] treatment of — for the production of fibre for spinning. W. P. Govaerts and G. A. M. Dreypondt. E.P. 8559, 4.4.14.

Reclaiming solvents. U.S.P. 1,345,083. See I.

Cellulose. G.P. 320,856. See IIA.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyes fast to chlorine; Method for rendering —. [Printing.] J. Brandt. Sealed note No. 1421. Bull. Soc. Ind. Mulhouse, 1920, 86, 28—30. Report by H. Bourry, *ibid.*, 30—31.

COLOURED effects obtained with printing pastes containing chrome mordant dyes having phenolic or acidic and basic groups are fast to chlorine if tannic acid be present. A blue reserve, fast to chlorine, on Para Red is obtained by the use of a printing paste consisting of 1 kg. of acid starch paste, 200 g. of Modern Violet 40% paste, 400 g. of chromium acetate 11° B. (sp. gr. 1.082), 400 g. of gum tragacanth (66 g. per l.), and 200 g. of a 50% tannic acid solution, with the usual subsequent development. A black reserve is obtained by the use of a paste composed of 1 kg. of starch paste, 50 g. of Brown salt G., 200 g. of Modern Violet, 400 g. of chromium acetate 11° B., and 360 g. of gum tragacanth (60 g. per l.), with the addition of 60 g. of sodium chlorate immediately before use. Bourry reports that the two printing processes are satisfactory, but that the tannin alters the shade of the dyes without much increasing their fastness to chlorine.

—A. J. H.

Aniline Black; Resists and conversions under —. P. W. Pluzanski. Sealed note No. 1468. Bull. Soc. Ind. Mulhouse, 1920, 86, 31—32. Report by M. Battegay. *Ibid.*, 32—33.

Blue or yellow resists are obtained by printing a paste containing caustic soda and 40 g. of stannous chloride per kg. on cloth prepared for Aniline Black with the usual padding liquor, but containing 50 g. of Indanthrene or Flavanthrene per kg., drying, rapidly ageing to develop the black, and then steaming in the absence of air for 6 mins. The alkaline resist paste may be suitably coloured, and if the cloth be first prepared with β -naphthol the resists can be developed with diazo compounds. Indigo may be used in place of Indanthrene if sodium hydrosulphite NF be present in the resist paste. Battegay reports the process to be satisfactory.—A. J. H.

PATENTS.

Bleaching treatment of open fabrics; Apparatus for —. E. W. Hunt. E.P. 145,113, 19.3.19.

AN ordinary bleaching kier contains a rectangular fabric chamber, two opposite sides of which are movable. The fabric enters the kier, is plaited down in open width by a suspended pair of electrically-driven nip rollers, compressed by the two movable sides, and bleached by the usual methods of boiling.—A. J. H.

Dyeing machine. F. L. Bickel. U.S.P. 1,344,788, 29.6.20. Appl., 31.5.19.

A DIAPHRAGM oscillates in the liquid chamber of the machine, whereby the fabric is compressed and periodically removed from the dye liquor.—A. J. H.

Printing cotton fabrics and yarns. The Calico Printers' Assoc., Ltd., W. Rouse, and G. Nelson. E.P. 145,240, 5.6.19.

THE alkaline discharge of alumina, iron, and chrome mordants is satisfactory in the presence of tannin. Cotton, mordanted with the tannates of aluminium, iron, or chromium, is printed with an alkaline mordant such as sodium aluminate or an alkaline lead solution, or a mixture comprising a caustic alkali, a reducing agent, and a vat or sulphur dye, aged or steamed, washed, and dyed by the usual methods.—A. J. H.

Glue substitute. G.P. 318,957. See XV.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Concentration of — [by the Strzoda tube system]. K. Mattenklodt. Chem.-Zeit., 1920, 44, 529 (cf. J., 1918, 688A).

By means of the Strzoda plant, used in conjunction with a Petersen pre-concentration tower, a strength of 97—98% may be reached from initial 50% acid. Working to 93—94% concentration, with an output of 10 tons per 24 hrs., a reduction of 1.34 tons of weak acid treated is effected as compared with other processes, such as the Gaillard, Kessler-Duron, Hartmann and Benker, and Pauling. Loss in the Strzoda process is negligible; about 1% of very weak acid (1° B.; sp. gr. 1.007) is obtained, whereas other plants show about 10% containing an appreciable amount of sulphuric acid which has to be recovered by re-concentration. The increased fuel consumption in the Strzoda plant, 1.8 ton per 10 tons 94% acid, as against 1.2—1.5 ton in other plants, is counterbalanced by the higher yield of concentrated acid, and smaller amount of weak acid obtained. By the employment of an iron-silicon alloy the wear and tear of the plant is reduced to a minimum.—W. J. W.

Ammonia-water; The system —. S. Postma. Rec. Trav. Chim., 1920, 39, 515—536.

THE author has constructed the melting-point, boiling-point, and vapour pressure curves of mixtures of ammonia and water and the sublimation curve of ammonia, and has deduced a formula for the variation of the vapour pressure of ammonia with temperature.—W. G.

Ferrous compounds; Catalytic action of copper salts on the oxidation of — by air. L. Maquenne and E. Demoussy. Comptes rend., 1920, 171, 65—69.

COPPER salts exert a marked catalytic action on the oxidation of ferrous salts by air even at extreme dilutions. It is most noticeable with ferrous salts of weak acids.—W. G.

Tin; Precipitation of — by iron. N. Bouman. Rec. Trav. Chim., 1920, 39, 537—541.

AN explanation of the fact that iron will not precipitate tin from a solution of stannous chloride is given, based on potential measurements. At the same time, it is shown that when reduced iron is boiled with a dilute acid solution of stannous chloride some tin is precipitated.—W. G.

Ammonium hydrogen fluoride; Titration of —. W. S. Chase. J. Ind. Eng. Chem., 1920, 12, 567—568.

TO avoid the interfering action of hydrofluoric acid on ordinary indicators in determining the acidity of ammonium hydrogen fluoride, the solution of the sample is treated with an excess of calcium chloride; an equivalent quantity of hydrochloric acid is liberated, and this is titrated without removal of the precipitated calcium fluoride. Methyl orange is used as the indicator.—W. P. S.

Thiocyanates in ammoniacal liquor etc. Shaw. See IIa.

Pickling solutions. Boyle. See X.

Acetic acid in acetates. Pickett. See XXIII.

PATENTS.

Sulphuric acid; Process and apparatus for removal of arsenic from —. G. E. Clark. E.P. 144,869, 29.5.19.

AN apparatus for treating sulphuric acid with a de-arsenicating gas, such as hydrogen sulphide,

without the use of a steam injector, comprises a tower with suitable baffles, through which the acid gravitates in the form of spray into a sealed container, also provided with baffles which cause the acid to flow in a zig-zag path. The reacting gas is blown by a fan into a holder, from which it is conveyed under pressure through a series of pipes, terminating in nozzles, and entering the container between its baffles. After passing through the acid in this vessel and effecting its de-arsenication, the gas is passed upwards through the tower and thus brings about a preliminary treatment of the descending acid.—W. J. W.

Sulphurous gases; Production of concentrated —. Farbenfabr. vorm. F. Bayer und Co. G.P. 304,262, 24.11.16.

GASES containing a low percentage of sulphur are passed over porous charcoal moving in the opposite direction, and the sulphurous acid absorbed by the charcoal is then recovered by careful heating. By keeping the charcoal in motion during the heat treatment the formation of carbon oxysulphide is prevented, and the sulphur dioxide content of the gases may be raised from 0.3% to 70%.—W. J. W.

Sulphur dioxide; Method of producing —. F. Laist and F. F. Frick. U.S.P. 1,344,905, 29.6.20. Appl., 9.6.19.

A MIXTURE of sulphur dioxide and oxygen is made to react with a substance containing sulphur. —W. J. W.

Oxides of sulphur; Manufacture of — from sulphates, specially calcium sulphate. Badische Anilin- und Soda-Fabrik. G.P. 306,313, 6.11.15.

THE sulphates, which may be mixed with combustible substances, are introduced in a finely-divided condition into oxidising flames, the air admitted being previously heated.—W. J. W.

Gases containing sulphur; Producing — suitable for the manufacture of sulphur and a magnesia sludge from magnesium chloride liquor. Harburger Chem. Werke Schön und Co., and W. Daitz. G.P. 306,441, 15.2.17.

IN the process for decomposing magnesium chloride liquor by means of calcium sulphide, a mixture of calcium sulphide and calcium oxide, prepared by roasting calcium sulphate together with lime or dolomite under the action of reducing fire-gases and steam, is employed instead of calcium sulphide alone. A small quantity of iron oxide may be added to the charge in the roasting process to regulate the action of the gases, provided that a product free from iron is not required.—L. A. C.

Sulphur; Process for obtaining — from calcium sulphate. Badische Anilin- und Soda-Fabrik. G.P. (A) 301,682, 4.11.16; (B) 302,471, 18.11.16; (C) 306, 312, 24.12.16.

(A) THE gases containing sulphur dioxide derived from the decomposition of calcium sulphate are mixed with carbon monoxide, or gases containing carbon monoxide, in presence of red-hot coal or coke. (B) Instead of, or in addition to, carbon monoxide, oxygen or air may be introduced in such excess that the gases, after leaving the combustion zone and on entering the reduction chamber, contain an appreciable proportion of oxygen. (C) When gypsum is employed for the production of the gases, it may be first dehydrated, the air introduced into the process being also completely dried. The yield of sulphur is practically doubled by this means.—W. J. W.

Nitrogen products [cyanides]; Apparatus for the production of —. C. T. Thorssell and H. L. R. Lundén. E.P. 145,299, 14.8.19.

IN the manufacture of cyanide by interaction of

nitrogen with coal and oxygen-containing compounds of alkali or alkaline-earth metals, at a high temperature, and under high pressure, the energy of the gas mixture at the end of the reaction may be utilised both for introducing the nitrogen into the reaction chamber and for other purposes. The gases leaving the reaction chamber at high temperature, and consisting largely of combustible gas (carbon monoxide), are led through a branch pipe on the nitrogen inlet pipe to an expansion engine, which operates a pump for driving the nitrogen under pressure to the reaction chamber. The gases leaving the expansion engine are then conveyed to a combustion engine or gas burner for further utilisation. The expansion engine and pump may be connected to two or more reaction chambers adapted to work alternately so that gas from one is used for compressing nitrogen for supplying another.—W. J. W.

By-products, particularly nitrogen compounds, from blast furnaces; Method of obtaining —. W. Ostwald, Assr. to The Chemical Foundation, Inc. U.S.P. 1,344,770, 29.6.20. Appl., 10.10.16. Renewed 25.11.19.

IN the treatment of ores in blast furnaces a hydrated chloride is added to the charge. The water of hydration, liberated as steam, acting in the ammonia-forming temperature zone, converts the nitrogen of the fuel into ammonium chloride, which is then separated from the blast-furnace gases. —W. J. W.

Aluminium nitride and the like; Production of —. M. Shoeld, Assr. to Armour Fertilizer Works. U.S.P. 1,344,153, 22.6.20. Appl., 10.7.19.

BRIQUETTES of aluminous and carbonaceous material are mixed with practically infusible resistor elements of substantial size which do not enter into the chemical reaction, and which are of greater electrical conductivity than, and prevent fusion of, the briquettes. Aluminium nitride is produced by heating the mixture by means of an electric current in an atmosphere of gas containing nitrogen. —A. R. P.

Aluminium nitride; Furnace for manufacture of —. G. Herman. G.P. 319,046, 23.10.14.

A FURNACE for treatment of bauxite with excess of nitrogen containing methane comprises chambers heated by gas (e.g., natural gas), divided into a number of smaller, vertical reaction chambers, in which the material is treated at a high temperature with reaction gases of high concentration, the process being carried out continuously by increasing the reaction velocity.—W. J. W.

Aluminium silicates; Treatment of natural —. W. Borchers. G.P. 300,684, 14.4.16. Addn. to 300,092 (J., 1920, 64A).

CARBONATES or hydroxides of the alkaline-earths may be substituted for the sulphates referred to in the original patent. During the roasting the silicic acid will combine with the alkaline-earth oxide, leaving the aluminium oxide in the finished product in a finely-divided condition, and readily susceptible to suitable solvents.—W. J. W.

Spent iron oxide; Furnace or kiln for burning —. W. Crowther. E.P. 145,366, 9.1.20.

A NUMBER of superposed burning compartments are arranged one above the other in a setting, each being provided with an arched roof leaving a space between the roof and the floor next above. The burnt gas passes through the roof into the space above and thence through side openings into a common vertical flue. The material on each floor is thus preheated by the gas from the chamber below. The burnt oxide is pushed out of the burning cham-

bers into a receiver at the back, and the light dust is deposited in the outlet flues.—W. F. F.

Sodium sulphite; Manufacture of —. E. O. Barstow, Assr. to The Dow Chemical Co. U.S.P. 1,343,897, 22.6.20. Appl., 25.6.18.

NITRE-CAKE is caused to interact with calcium sulphite, the acid sodium sulphite produced being then treated with milk of lime.—W. J. W.

Potassium; Treatment of minerals containing —. A. Messerschmitt, Assr. to The Chemical Foundation, Inc. U.S.P. 1,341,705, 29.6.20. Appl., 11.12.14.

SILICATES containing potassium are finely ground, mixed with sodium nitrate, and heated to a high temperature, under pressure, in presence of water. —W. J. W.

Potash [from silicates]; Recovery of —. A. C. Spencer. U.S.P. 1,344,830, 29.6.20. Appl., 17.11.15.

AMORPHOUS silicates containing potassium are heated under pressure with a neutral salt of a strong base, in presence of a solvent, strong bases or acids being absent. The salt equivalent should be about 15 times that of the potassium present. —W. J. W.

Sodium silicofluoride; Preparation of — and hydraulic cement. W. Esch. G.P. 319,559, 27.3.19.

SILICIC acid, fluorspar, and magnesium sulphate are roasted together in a rotary furnace, and the silicon tetrafluoride evolved is passed into a solution of sodium chloride. The residual product in the furnace, on account of its content of magnesium oxide and calcium sulphate, may be employed as a hydraulic cement.—W. J. W.

Salts of heavy metals; Manufacture of —. H. Kühl. G.P. 308,396, 23.6.17.

SALTS of heavy metals are prepared by heating a mixture of an oxide, hydroxide, or carbonate of a heavy metal and an ammonium salt of a strong acid; e.g., by heating a mixture of iron oxide and ammonium sulphate in a stream of air, ammonia is liberated and iron sulphate is formed at a little above 100° C.—L. A. C.

Magnesium arsenate; Method of making —. E. O. Barstow, Assr. to The Dow Chemical Co. U.S.P. 1,344,018, 22.6.20. Appl., 16.9.18.

AN aqueous suspension of magnesium hydroxide is mixed with a solution of arsenic acid.—A. R. P.

Lead arsenate; Manufacture of —. O. F. Hedenburg and D. S. Pratt, Assrs. to The Toledo Red Spray Co. U.S.P. 1,344,035, 22.6.20. Appl., 1.7.19.

FINELY-DIVIDED lead oxide is suspended in a liquid medium, free from electrolytes other than those resulting from partial hydrolysis of the oxide, and arsenic acid or oxide is added, whereby lead arsenate is produced in a fine, crystalline form suitable for use as an insecticide.—W. J. W.

Potassium perchlorate; Cyclic process for the manufacture of —. Oberschlesische A.-G. für Fabr. von Lignose. G.P. 298,991, 25.12.15.

A SOLUTION of sodium perchlorate obtained by electrolysis is treated with potassium chlorate, and the solution of sodium chlorate formed, after addition of sodium chloride to replace the small loss of Na ions, is again electrolysed.—L. A. C.

Potassium chlorate; Electrolysis of solutions of — to prepare potassium perchlorate. Oberschlesische Sprengstoff A.-G. G.P. 300,021, 7.12.15.

A SOLUTION of potassium chlorate is electrolysed at

27° C., using nickel cathodes and a current density of about 0.15 amp. per sq. cm. of cathode surface.

—L. A. C.

Bromates; Manufacture of —. C. W. Jones, Assr. to The Dow Chemical Co. U.S.P. 1,343,918, 22.6.20. Appl., 25.6.18.

A SOLUBLE bromate is separated from admixture with other salts by converting it into barium bromate, which is relatively insoluble.—A. R. P.

Hydrogen; Manufacturing of —. The British Oxygen Co., Ltd., S. W. Bray, and I. H. Balfour. E.P. 111,751, 11.2.19.

THE spent gases issuing from a unit in which iron oxide has been reduced by producer gas to metallic iron to be used in the manufacture of hydrogen are treated by known methods, e.g., condensation or absorption, to remove the greater part of the water vapour, carbon dioxide, and sulphur compounds. The purified gas is then used to reduce a further charge of oxide.—A. R. P.

[Oxidising] catalyst, and process of making it. J. C. W. Frazer and C. C. Scalone. U.S.P. 1,345,323, 29.6.20. Appl., 4.2.19.

A HYDRATED metal oxide is precipitated in an extremely finely divided condition, washed free from soluble matter, and compressed into a cake which is dried at a low temperature in a current of gas containing free oxygen.—W. J. W.

Flue dust. U.S.P. 1,345,034. See X.

Lime-potash fertiliser. U.S.P. 1,345,077. See XVI.

VIII.—GLASS; CERAMICS.

"Soda composition" [as substitute for sodium carbonate in glass manufacture]. L. Springer. Sprechsaal, 1920, 53, 310—313.

THE term "soda composition" or "glass composition" is applied to a number of materials used as substitutes for sodium carbonate in glass manufacture. One of these compositions was found to be completely soluble in water and to consist of sodium carbonate 81.0, barium peroxide 2.0, iron oxide 0.013, and water 16.4%. Other compositions consisted of powdered bluish-green soda-lime glass (cullet) with 20% of soda; soda 18, chalk 17, rock salt 60, and fluorspar 5%; and impure rock salt. The presence of calcium sulphate in such compositions is objectionable, as it forms scum on or "seeds" in the glass. Barium carbonate (with or without barium peroxide) is a popular substitute for soda and potash. If all the lime in a batch mixture is replaced by twice its weight of barium carbonate, the glass melts more readily and fines rapidly. If part of the alkali is omitted, the glass still melts readily, but is liable to be stony. If part of the alkali is replaced by baryta a readily fusible and rapidly fining glass is produced. When the lime is only partially replaced by baryta the glass melts well, and the fining is much improved. A saving in potash can only be effected by forming a true barium glaze without lime, or when part of the lime and a small part of the alkali are replaced by barium carbonate. When fluorspar is used as a substitute for alkali, the glass appears to melt readily; this is not due to the direct fluxing action of the spar, but to the volatilisation of some of the sand whereby the silica-content of the mixture is reduced; at the same time the quality of the glass is impaired. Attempts have been made recently to use a specially purified sodium sulphate free from iron as a substitute for soda in crystal glass, but it is doubtful whether so highly purified a sulphate is as cheap as soda, and whether a wholly white crystal glass can be prepared from it. Sodium

silicofluoride and other fluorine compounds are also used as substitutes for soda and as opacifiers, especially in association with kaolin and felspar. Sodium silicofluoride has the same disadvantages as fluorspar and, in addition, it tends to make the glass turbid, especially if alumina is present. Sodium fluoride is also used as a substitute for boron and arsenic compounds, and as a fining accelerator.—A. B. S.

Glass batches containing lime; The choice of —. W. E. S. Turner. J. Amer. Ceram. Soc., 1920, 3, 379–383.

In the manufacture of glass bottles, batch mixtures containing about 300 parts of limestone to each 1000 parts of sand are used for hand-worked glass, but not in works employing automatic machines. In the latter the use of a glass with so high a lime content would be attended with difficulty, and a "lime-flint" glass with a low proportion of lime and a higher proportion of alkali (soda ash and Chile saltpetre) is preferable, as it is more fusible, remains plastic for a longer time and at a lower temperature, has a lower thermal conductivity, and a higher coefficient of expansion, and requires a lower annealing temperature. The durability and resistance of the lime-flint glasses towards air and liquids is reduced as the proportion of alkali is increased and, for this reason, glasses containing less than 7% of lime or less than 166 parts of limestone or more than 412 parts of soda ash per 1000 parts of sand should be avoided.—A. B. S.

Optical glass; Twenty-three types of —. R. J. Montgomery. J. Amer. Ceram. Soc., 1920, 3, 401–410.

On plotting the dispersion and refractive index of various optical glasses as abscissæ and ordinates, respectively, it was found that there are 23 ordinary types of optical glass, composed of:—(a) Fundamental oxides (SiO_2 , K_2O , Na_2O , CaO , PbO , ZnO , B_2O_3) affecting the optical properties, and (b) control chemicals affecting the fusibility of the glasses, i.e., the "proportioning" of carbonates, nitrates, chlorides, and sulphates or the use of arsenic and antimony. Sometimes a fundamental oxide may be used as a control chemical. A diagram shows that very large changes in composition are needed to change the optical properties appreciably, yet if the refractive index and dispersion are to be kept constant only very small variations in composition can be permitted, a variation of 0.1% in the fundamental oxides affecting the third decimal place of the refractive index and the first decimal place of the dispersion. The diagram also shows that there is a natural field in which each oxide has its normal use, though it may be employed in other fields for secondary purposes. Thus, the long, narrow lead zone extends from the "telescope flint" to the densest silica flint, the lead from 10–80% of the batch, and the refractive index from 1.50 to 1.96, and the dispersion from 57.0 to 19.7. To the right of the lead zone barium and zinc are introduced, ranging from dense baryta flint (with 10% barium and 5% zinc) through baryta flint to baryta light flint with 15% barium and 10% zinc. The zinc is highest (15%) in a baryta light flint and dense barium crown; it decreases as the dispersion increases to about 2% in the soft silicate crown and ordinary crown. The soda-lime field includes the ordinary crown, whilst the telescope crown is a soda-lime glass with boric and barium oxides. The "light silicate crown" field overlaps some of the others; it contains 5–10% of boric oxide. The borosilicate crown of high refractive index contains about 10% of boric oxide, and is rather high in alkali, whilst the ordinary borosilicate crown contains 10–15% of boric oxide and may contain 2–4% of barium oxide or alumina. When a new glass is required of any given refractive index and disper-

sion its composition may be roughly determined by extrapolation on the diagram.—A. B. S.

Glass; Measurements on the thermal dilatation of — at high temperatures. C. G. Peters and C. H. Cragoe. J. Opt. Soc. Amer., 1920, 4, 105–144.

THE dilatation of 32 different kinds of glass was measured by means of the Fizeau-Pulfrich interferometer at temperatures between 20° and 650° C. The curves drawn from the figures so obtained show that the glass passes through a critical expansion region in which the rate of expansion increases 2–7 times; this region, which does not exceed 40° C. for any glass examined, was found as low as 400° C. with a barium crown and as high as 575° C. with a lead glass. About 75° C. above the critical region the glass softens and contracts. The results of such dilatation measurements give information as to the temperature for most careful and thorough annealing, the upper limit for rapid annealing, and the region where careful cooling is essential.

Kaolins; Elutriation tests on American —. H. G. Schurecht. J. Amer. Ceram. Soc., 1920, 3, 355–378.

A NUMBER of American kaolins were elutriated in a modified Schulze's apparatus, consisting of a series of four cans, the upper parts of which were cylindrical and the lower parts conical. The diameter of the cans and the speed of liquid passing through them were adjusted to secure the velocities specified by Seger for separating silt and clay substance, and for dividing the latter into three fractions. In carrying out the process the clay is crushed to pass completely through a No. 4 sieve, after which 500 g. is thoroughly blunged with water in a 2-quart churn, sifted, and the slip which has passed through a 200-mesh sieve is deflocculated by the addition of a little caustic soda and admitted to the elutriator drop by drop. The rate of flow must not exceed two-thirds of the maximum velocity until all the slip has been added. To avoid flocculation as the caustic soda is washed out of the clay, a little dilute ammonia is added periodically to the water passing through the elutriator. The elutriation requires three days. The residue in each can is then collected, dried, and weighed, and the size of grains measured under a microscope as a check. Distilled water should be used throughout, as the soluble salts in tap-water cause partial coagulation. The observed diameters of the particles agree well with those calculated by Schöne's formula. When tested in this manner, kaolins from Georgia, South Carolina, and Pennsylvania resembled English china clay in containing a large percentage of particles below 0.010 mm. diameter (Seger's "clay substance"), but those from North Carolina contain only a low percentage of these minute particles. As English ball clays contain 98.55% of very fine grains carried away by a current with velocity of 0.0197 mm. per sec. whereas china clay contains only 40%, it is suggested that the greater plasticity of ball clays is due to the large proportion of these minute grains.—A. B. S.

Terra-cotta bodies; Effect of variation of the size of grog in —. R. L. Clare and D. F. Albery. J. Amer. Ceram. Soc., 1920, 3, 384–387.

VARIATIONS in the character, quality, and size of particles of the grog used in the manufacture of terra-cotta bodies cause corresponding variations in the bodies. Coarse grog (33% on 14-mesh, 12.3% of 20-mesh, 33% on 40-mesh, and 21% through 60-mesh) reduces the drying shrinkage and increases the difficulties in pressing and finishing and in preventing warping. It makes the burned ware weak and the glaze covering poor. Fine grog (1.5%

on 20-mesh, 28.9% on 40-mesh, 20.3% on 60-mesh, 15.1% on 100-mesh, and 31.2% through 100-mesh) facilitates production, but the goods tend to crack when drying and to warp when burned. Grog of medium size (e.g., 11.5% on 14-mesh, 8.2% on 20-mesh, 34.3% on 40-mesh, 13.4% on 60-mesh, 5.7% on 80-mesh, 4.4% on 100-mesh, and 22.5% through 100-mesh) gives the best results. It is, therefore, necessary to select the raw material and to burn and grind it under carefully controlled conditions.

Ruby-glass; Manufacturing — M. Meth. Assr. to The Lancaster Lens Co. U.S.P. 1,311,131, 22.6.20. Appl., 22.11.18.

SUITABLE quantities of antimony sulphate and crude tartar are mixed with the ordinary transparent glass ingredients.—H. S. H.

Furnaces for melting glass and other purposes. J. S., S. H., and A. E. Shaw. E.P. 111,744, 21.12.18.

Cold air is heated by passing through longitudinal flues lying between the bottom of the tank or bath and longitudinal flues conveying the waste gases, in the opposite direction to the air, to the chimney. After further heating by passing through longitudinal flues above the combustion chamber, the air mixes with the gas and enters the combustion chamber.—H. S. H.

Refractory product and method of making the same. C. W. Thomas. U.S.P. 1,311,461, 22.6.20. Appl., 7.8.18.

UNBURNED raw quartzite is mixed with Portland cement, a hardener, and water. After moulding and allowing to set, the mixture is heated sufficiently to calcine the cement and sinter the refractory material.—H. S. H.

Hardened material. U.S.P. 1,343,976—7. See X.

IX.—BUILDING MATERIALS.

Blast-furnace slag; Experiments with — H. Burchartz. Stahl u. Eisen, 1920, 40, 814—819.

THE final results of a series of tests (extending over 5 years) made on blast-furnace slags to ascertain their suitability for use in making concrete, are given and collated with the results obtained after 1, 2, and 3 years. The slags showed no alteration after storage in the open for 5 years, and concrete containing the slags gave no indication of having altered during the period 3 to 5 years. The results in general confirm the conclusions which had been drawn from the shorter period tests, viz., that it is possible to obtain equally good concrete with blast-furnace slags as with gravel.—T. St.

Concrete; The use of boiler-clinker for — Nitzsche. Zement, 1920, 9, 146—148, 152—156, 158—160, 195—197. Chem. Zentr., 1920, 91, IV., 83.

BOILER clinker to be suitable as an aggregate for concrete should have a volume-weight, when loosely filled, of 0.72, sp. gr. 2.15. A concrete made of porous aggregate has a greater volume-weight and strength than one in which a denser aggregate is used, as in the former the grains can be compressed more closely together. Sand-cement concretes are stronger than those devoid of sand. In slag concretes with slag and cement in the ratio of 1:4.5 or 1:7 the volume-weight is between 1.1 and 1.6 and the porosity between 21 and 33%; the absorption is less than that of bricks. It is necessary to control the proportion of sulphates and ferrous oxide to avoid unburnt material.

—A. B. S.

Anhydrite; Use of — for mortar. F. Hartner. Z. angew. Chem., 1920, 33, 175—176.

THE slowness with which anhydrite sets has so far militated against its use for mortar. If, however, it is ground to pass a sieve of 5000 meshes per sq. cm., hardening takes place in the course of a few hours. With a coarser material the same result may be obtained by the addition of 1—3% of lime or Portland cement, the product differing little from flooring plaster. A sample mixed with 20—25% of water to a stiff paste began to set in 2 hrs. and hardened in 4—7 hrs.; the tensile strength of anhydrite mixed with 15% of water was 20—25 kg. per sq. cm. after 21 hrs. The tensile strengths of mixtures of anhydrite and lime in the proportions of 1:1; 1:2; 1:3; with 7, 6, and 5% of water added, after 3, 7, and 28 days, were respectively 15, 20, 50; 12, 14, 25; and 8, 10, 16 kg. per sq. cm. Resistance tests on the same samples gave 200, 300, 500; 180, 240, 320; and 80, 110, 160 kg. per sq. cm. Comparisons of the effect of the fineness of the material on its tensile strength were made on samples to which 1% Portland cement was added after periods of 1, 2, 3, 7, and 28 days. The results were 10, 13, 14, 19, 30; 18, 20.5, 21.5, 25.5, 35.5; 22, 24, 25, 34, 39.5 kg. per sq. cm. Fuel consumption in the case of anhydrite-mortar amounts to about 6—10%, as against 20—30% with lime, 15—30% with gypsum, and 40—60% with Portland cement. In addition no loss results in manufacture, whereas the losses with lime, gypsum, and Portland cement are approximately 45%, 20%, and 35%.—W. J. W.

PATENTS.

Cement; Process for producing — of liquid slags in electric furnaces. K. G. Wennerström. U.S.P. 1,313,948, 22.6.20. Appl., 29.3.20.

LIME or limestone in broken pieces is delivered upon the surface of a bath of liquid slag, and an electric current is passed through the slag bath to melt the lime and cause it to combine with the slag to form the cement.—H. S. H.

Wood; Method of preserving — M. Rüping. U.S.P. 1,315,253, 29.6.20. Appl., 14.12.16.

WOOD is subjected in a closed retort to the action of heated air under pressure, followed by heated creosote oil, injected at a higher pressure. When the walls of the pores and cells have become coated with creosote, the excess of oil is drawn off, the pressure relieved, and the air imprisoned in the wood allowed to escape.—A. B. S.

Lagging material; Manufacture of — “Lipsia” Chem. Fabr. G.P. 318,885, 25.11.17.

BASIC magnesium carbonate, obtained in a flocculent condition by heating ammonium magnesium carbonate with water, is mixed with a fibrous material, either during or after the boiling process. The filtered and dried product is very light and has a very low heat-conductivity.—W. J. W.

Cement. G.P. 319,559. See VII.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ore; Electric smelting of — with coke. G. Stig. Chem. and Met. Eng., 1920, 23, 29—31.

IN the electrothermic smelting of iron ore the best results, technically as well as economically, are obtained with furnaces capable of utilising a large amount of power. A consideration of the present types of furnaces, both single and with several shafts, points to the Electrometal type having the greatest possibility of development. The largest furnace of this type built is for 7200 kw., but it is

possible to construct furnaces for 12,000 to 15,000 kw. provided electrodes of high quality are available. In working it is shown from actual operations that the most important factors are the rate of melting; the dimensions of the furnace hearth; the shape and height of the furnace; the voltage, current, current density, and arrangement of the leads; the composition of the charge; and the gas circulation. A slow melting rate causes bridging of the charge and the production of cold iron; an improperly dimensioned furnace tends to bring about graphitisation of the coke. A certain relation is necessary between the voltage, current, and current density to obtain uniform heating, and an adequate gas circulation both to promote uniform heating and to increase reduction by the gases. The efficiency of an Electrometal furnace operating with coke for four weeks was about 67% and the average production per day 23 metric tons.

—J. W. D.

Steels; Effect of the time of adding silicon during the preparation of open-hearth —. E. Piwowarsky. *Stahl u. Eisen*, 1920, 40, 773—781.

A SERIES of experiments was carried out on open-hearth steel charges to determine the effect of the time of adding silicon (as ferrosilicon) to the bath on the properties and gas content of the resulting steel, with the following general results. With too early addition of ferrosilicon the high temperature of the bath favours the formation of silicates, consequently the ferrosilicon acts as a deoxidiser and a large proportion of the silicon passes into the slag. The amount of silicon lost in this manner varies from 18 to 35% using 45% ferrosilicon. If, however, the addition is made just previous to finishing, only 3.2—6.7% of the silicon forms deoxidation products and a steel of higher silicon content is obtained. Addition of ferrosilicon as late as possible also reduces the gas content of the steel in its fluid and solid, as well as in its rolled condition.—J. W. D.

Iron; The determination of oxygen in —. II. P. Oberhoffer and O. von Keil. *Stahl u. Eisen*, 1920, 40, 812—814.

THE apparatus and method originally described (see this J., 1919, 256 A) have been simplified. By the modified method each determination requires 52 minutes for completion, but in continuous work results are obtained at intervals of 32 minutes.

—T. St.

Sulphur in pig-iron, steel, ores, slags and fuels; Determination of — by combustion in oxygen.

A. Vita. *Stahl u. Eisen*, 1920, 28, 933—938.

THE gases produced by combustion of pig iron or steel at about 1200° C. in oxygen are passed into a solution of potassium iodide and potassium iodate, the liberated iodine colouring the solution, which is then compared with a standard scale of solutions coloured with potassium bichromate corresponding to steps of 0.01% S. A determination requires 5—10 mins. This process is also applicable to ores, slags, and fuels, the temperature being raised to 1350° C. to ensure complete combustion of the sulphur compounds, but instead of colorimetric comparison the liberated iodine is titrated with N/10 or N/4 sodium thiosulphate. In cases where the sulphur is sublimed on heating, a platinum spiral is introduced which ensures the formation of sulphur trioxide.—T. H. Bu.

High-speed steel; Analysis of —. H. O. Ward. *Chem. and Met. Eng.*, 1920, 23, 28.

A METHOD of analysing high-speed steel is described in which the original feature is the solution of the tungsten and the determination of the manganese, chromium, and vanadium, using a single sample and without filtering during the operation. The

steel is dissolved in a solution of sulphuric acid and silver nitrate, and when solution is complete a nitric-phosphoric acid solution is added and the liquid boiled until the tungsten disappears. The chromium, vanadium, and manganese are next oxidised in order with ammonium persulphate and the manganese titrated with standard sodium arsenite solution. The silver nitrate is then precipitated with hydrochloric acid, excess of ammonium persulphate boiled off, and the chromium titrated with standard ferrous ammonium sulphate, standard potassium permanganate, and standard sodium arsenite solutions. The vanadium is determined immediately by adding standard ferrous ammonium sulphate, destroying the excess with ammonium persulphate, running in standard potassium permanganate solution, and titrating back the excess with standard sodium arsenite solution as before.—J. W. D.

Steel; Determination of zirconium [and titanium] in —. G. E. F. Lundell and H. B. Knowles. *J. Ind. Eng. Chem.*, 1920, 12, 562—567.

FIVE g. of the steel is dissolved in hydrochloric acid with the addition of a small quantity of nitric acid, the silica is separated, the acid solution evaporated to a syrup, 40 c.c. of hydrochloric acid (sp. gr. 1.1) added, and the greater part of the iron and molybdenum is extracted with ether. The acid solution is heated to expel dissolved ether (matter remaining after treating the silica with hydrofluoric acid and dissolved by fusion with pyrosulphate is added at this stage), and an excess of 20% sodium hydroxide solution is added. The precipitate formed is collected, dissolved in hydrochloric acid, and re-precipitated with sodium hydroxide. The precipitate is once more dissolved in hydrochloric acid, the solution diluted to 250 c.c., partially neutralised with ammonia, 2 g. of tartaric acid is added, and the whole treated with hydrogen sulphide until all iron has been reduced. A slight excess of ammonia is then added, and the precipitate formed collected, and washed with dilute ammonium sulphide-ammonium chloride solution. The filtrate is neutralised with sulphuric acid, diluted, heated to expel hydrogen sulphide, filtered, and the filtrate, measuring 400 c.c. and containing 10% of sulphuric acid, is cooled to 0° C., and treated with 6% "cupferron" solution. The precipitate is collected after 10 mins., washed with cold 10% hydrochloric acid, ignited, and weighed. This ignited residue consists of zirconium and titanium oxides; it is fused with potassium pyrosulphate, the melt dissolved in 50 c.c. of 10% (by vol.) sulphuric acid, and the titanium determined colorimetrically or volumetrically. The weight of titanium oxide found is deducted from that of the mixed oxides to obtain the quantity of zirconium oxide. The combined filtrates from the sodium hydroxide precipitates obtained as above may be used for the determination of the aluminium present, and directions are given for this determination when the steel also contains chromium, uranium, and vanadium.—W. P. S.

Oxygen in cyanide solutions [; Determination of —]. E. M. Hamilton. *Eng. and Min. J.*, 1920, 110, 116.

WHITE'S method for the estimation of oxygen in cyanide solutions (J., 1918, 547 A) depends on the degree of coloration imparted to a cyanide solution by the addition of either methyl orange, acid, and potassium chromate, or a solution of pyrogallol and caustic soda oxidised to saturation and then diluted to the shade required. By the first of these methods it is difficult to obtain a match, while in the second the colour produced fades in daylight, thus preventing its use as a standard for more than a brief period. A perfect colour match is obtained by the use of a solution of caramel; the

ting appears to be permanent as far as could be observed in a period of three to four weeks, a slight fungoid growth produced after ten or twelve days being prevented by the addition of formaldehyde. Determinations by this modified method can be made to 1 mg. of oxygen per litre.—J. W. D.

Pickling solutions; Indicators used for determining free acid in —. C. L. Boyle. *J. Ind. Eng. Chem.*, 1920, 12, 571–572.

The presence of a large quantity of ferrous sulphate in pickling solution interferes with the observation of the end-point of the titration of the acidity when ordinary indicators are used, but sodium or potassium thiocyanate solution may be used for the purpose. Ten c.c. of the pickling solution is treated with a few drops of the thiocyanate solution and titrated with standardised alkali solution until the red colour of the ferric thiocyanate disappears. The pickling solution should not be diluted before titration.—W. P. S.

Zinc and copper; The constituents formed by reciprocal penetration of — at a temperature at which these two metals and all their alloys are in the solid state. H. Weiss. *Comptes rend.*, 1920, 171, 108–111.

CONTACT was obtained either by rapid cooling, after immersion of copper in zinc melted under zinc chloride, or by driving a cylinder of zinc into a hole made in a cylinder of copper. When these metals were heated under such close contact at 400° C. for 2 days the constituents detected were pure zinc or its solid solution η ; the constituent ϵ , thickness 0.2 mm.; the γ constituent, thickness about 1 mm.; a very thin zone of the β constituent, and copper or its solid solution α . If the time of heating was increased to 10 days the thickness of the zones ϵ and γ increased without appreciable alteration of the zone β .—W. G.

Blast-furnace slags. Burchartz. See IX.

PATENTS.

Iron; Manufacture of grey —. G. J. Stock. E.P. 143,596, 19.2.19.

WHITE iron is first produced and desulphurised in a smelting furnace at 1200°–1300° C., then transferred to an electrical or other refining furnace and heated in the presence of a desulphurising slag and sufficient carbon and silicon to 1500° C.—J. W. D.

Steel; Process of manufacturing —. R. H. Irons, Assr. to Central Iron and Steel Co. U.S.P. 1,345,192, 29.6.20. Appl., 11.8.19.

IS the "scrap and carbon" process of manufacturing steel a material containing manganese is supplied to a charge of scrap steel and carbonaceous material, in a basic open-hearth furnace, in such quantity as to provide residual manganese throughout the refining operation.—J. W. D.

Iron; Hardening — by means of a mixture containing titanium. R. Eichler. G.P. 319,971, 10.6.17.

IRON hardened by a mixture containing titanous acid or other titanium compound, potassium carbonate, carbon, and leather charcoal or other compound rich in nitrogen does not lose its hardness when made red hot.—L. A. C.

Steel, iron, and similar articles; Treatment of —. H. C. Barnes, Assr. to The Cleveland Metal Products Co. U.S.P. 1,344,372, 22.6.20. Appl., 6.9.16.

THE articles are treated with a solution of a phosphorus compound capable of depositing with or forming a protective coating in the presence of an agent evolving nascent hydrogen in the solution. —J. W. D.

Rust-preventing process for needles, knitting pins, hat pins, and other articles. The Redditch Electro-Plating Co., Ltd., and J. Guise. E.P. 145,116, 19.9.19.

THE articles are first immersed in a solution of caustic potash in water to which bismuth and plum-bago have been added, then electro-plated with a suitable metal (e.g. nickel), and finally immersed and agitated in a solution of water, soap, soda, and lime before drying.—J. W. D.

Electric welding of iron, steel, or alloys thereof; Means [flux] to be employed in —. A. Hyde. E.P. 141,842, 1.5.19.

THE flux (e.g. asbestos and sodium silicate) described in E.P. 128,463 (J., 1919, 610 A) applied to wires etc. for welding is not vitrified but heated only to 700°–800° C., so that only the sodium silicate becomes fused, in which condition the flux adheres well to the metal, but when completely fused under the electric arc is easily detached when required.—B. M. V.

Metallic oxides; Reducing —. A. E. Bourcoud. U.S.P. 1,341,977, 29.6.20. Appl., 17.6.18.

THE oxides are brought into contact at high pressure with a reducing gas formed by mixing a non-combustible gas with atomised fuel at a high temperature.—J. W. D.

Metallurgical process. Process for treating liquids with gases. W. E. Greenawalt. U.S.P. (A) 1,344,030 and (B) 1,344,031, 22.6.20. Appl., 11.8.17 and 5.1.17.

(A) A gas is confined over a liquid, which is mixed with the gas (e.g. by spraying) and at the same time electrolysed, so that additional gas is supplied to make up for that absorbed by combination with the constituents of the liquid. In (B) the gas is sulphur dioxide and the liquid dilute sulphuric acid.

—B. M. V.

Furnace; Electrically heated — [for metals, ores, etc.]. Morgan Crucible Co., Ltd., and C. W. Speirs. E.P. 144,802, 17.3.19.

AN electrical furnace for melting or heating metals or ores comprises a boat-shaped trough with spout, having end extensions on which may be clamped suitably-shaped terminals for the supply of single-phase current, these terminals being hollow to allow cooling water to circulate through them. The trough container is surrounded by a metal casing, extending above its top, to form a receptacle for gradually charging bulky scrap into the trough, the space between the trough and casing being filled with refractory insulating material. Flues are arranged for the removal of fumes during the operations of heating or pouring. The apparatus admits of the use of heavier charges of metal than heretofore, and, by avoiding the necessity for very thick walls for the melting vessel, enables current of higher voltage and lower amperage to be employed. (cf. J., 1913, 1019; 1919, 686 A.)

—W. J. W.

Roasting-furnace; Gas-heated —. Donnersmarckhütte, Oberschlesische Eisen- und Kohlenwerke A.-G. G.P. 319,716, 20.7.18. Addn. to 310,283 (J., 1919, 641 A).

MECHANICAL rabbles are arranged in the zone of the furnace which is at the critical temperature of the combined water, so as to move the ore over the less steeply inclined plates (cf. J., 1920, 69 A, 457 A).

—A. R. P.

Metals; Process of extracting —. C. J. A. Dalziel. U.S.P. 1,344,681, 29.6.20. Appl., 17.1.20.

FINELY divided metalliferous ores are agitated in a leaching solution at atmospheric temperature by

a blast of air of sufficient intensity to form a readily flowing thin pulp, and the pulp, still agitated by the air blast to prevent sedimentation, is passed through a series of electrolytic cells.—J. W. D.

Flue-dust; recovery of solubles from —. R. B. Stringfield, Assr. to International Precipitation Co. U.S.P. 1,345,034, 29.6.20. Appl., 7.12.17.

FLUE-DUST containing calcium, potassium, and sulphate radicles is treated with water to produce a solution containing calcium sulphate and potassium sulphate and an insoluble double sulphate of calcium and potassium. The concentrated solution is then separated from the insoluble salt, which is further treated with water to extract potassium sulphate.—J. W. D.

Hardening material for use as substitutes for diamonds, etc. A. J. Liebmann and C. A. Laise, Assrs. to Independent Lamp and Wire Co. U.S.P. (A) 1,343,976 and (B) 1,343,977, 22.6.20. Appl., 5.5.17 and 23.11.18.

(A) HARD materials suitable for use as wire drawing dies or as substitutes for jewels are produced by pressing substantially pure refractory metal powder into suitable shapes, and hardening these at a white heat between suitable electrodes embedded in a powdered mixture of carbon and a rare-earth oxide. (B) A mixture of refractory metal and powdered carbon is pressed into shapes, baked, and sintered at a white heat.—J. W. D.

Hard lead; Substitute for — for acid-resisting ware. W. Stockmeyer and H. Hanemann. G.P. 305,611. Addn. to 301,721 (J., 1920, 161 A).

Metacholesterol; Preparation of —. J. Lifschütz. G.P. (A) 318,900, 17.2.17, (B) 318,901, 2.3.17.

(A) CHOLESTEROL or substances containing cholesterol are treated with mild oxidising agents until the formation of oxidation products of cholesterol is just detectable by the acetic-sulphuric acid reaction. Metacholesterol, m.p. 140°—141° C., crystallises in glittering leaflets from alcohol, in which it is considerably more soluble than is cholesterol. It gives no colour reaction with the acetic-sulphuric acid reagent, nor with ferric chloride. The alcoholic solution gives after addition of water and evaporation of the alcohol an opalescent colloidal solution which can retain in suspension large quantities of fats or higher alcohols. Fats or oils or vaseline melted with 2% of metacholesterol can take up over 500% of water. (B) Metacholesterol is prepared from animal substances containing cholesterol by treating them with solvents in the usual way, so that the cholesterol is first thrown out as a solid, and then, on concentrating the filtrate, it separates

out, leaving mainly oxysterol in the solution. Or the material containing metacholesterol, *e.g.*, ox brain or blood fat, is treated with volatile solvents and water, or with water alone, the liquid is dialysed or filtered, and the dissolved substance subjected to the above fractional separation by means of solvents in order to obtain a more concentrated preparation of metacholesterol.—G. F. M.

Oil seeds. *ti.* P. 320,856. See IIa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Ink in writing; Determination of the age of —.
C. A. Mitchell. Analyst, 1920, 45, 217–256.

THE evolution of writing inks, artificial ageing of inks, microscopical differences in old and recent inks, colour of old and new inks in writing, methods of recording the colour, influence of blotting on the colour, sequence of strokes as proof of prior writing, copying methods, chemical tests for age, and chemical changes in the drying of ink are dealt with, and each of these points is shown to be of value as supplying possibly important information regarding the age of writing. The most useful chemical reagent is a 5% oxalic acid solution; a drop is applied to the writing and the effect noticed under a lens. In old blue-black ink writing the Aniline Blue, if still present, is prevented from diffusing by the insoluble tannate which has formed. Many instances of the value of one or another of the tests are given.—W. P. S.

Furfuraldehyde; Action of — on phenols [artificial resins]. E. Beckmann and E. Dehn. Sitzungsber. Preuss. Akad. Wiss., 1918, 1201–1221.

THE prospect of large quantities of furfuraldehyde becoming industrially available induced an inquiry as to how far it possesses the technically valuable properties of formaldehyde. The condensation products from furfuraldehyde and phenols are black in colour but otherwise have all the essential characteristics of bakelites. Thus, a mixture of phenol, furfuraldehyde, and 39% hydrochloric acid (most suitably in the proportions 5:5:1–2) becomes warm and gradually solidifies, contracting away from glass or porcelain, but not from metal surfaces, and after 24 hours is sufficiently hard to be only faintly scratched by gypsum, still retaining a certain elasticity. It is the complete analogue of Bakelite C in its insolubility in acids or alkalis, even at the boiling point, or in organic solvents. Its fracture is similar to that of vulcanite, and it can be worked on the lathe, any tendency to attack the metal being easily removed by warming, which renders it somewhat harder and more brittle. Of the 24 other compounds of which details are given, crude cresol, guaiacol, carvacrol, and β -naphthol gave the best results, the proportions employed in each case being 10:10:1. Alcoholic hydrochloric acid can also be used to promote reaction, any excess being removed at a temperature not exceeding 60° C.; and the products have the advantage of complete homogeneity, without the variations in hardness observed when aqueous acid is employed. By the addition to the original mixture of certain substances, of which the most efficient were “laneps,” coal tar, kieselguhr, sawdust, cellulose, and asbestos, the product was much improved in plasticity and not otherwise impaired. The influence of hydrobromic and hydriodic acids, or the chlorides of weak bases, *e.g.*, zinc, aluminium, and cuprous chlorides, was similar to that of hydrochloric acid, and solid products were also obtained by the aid of sulphuric and phosphoric acids. Organic acids do not induce condensa-

tion. Ammonium chloride and hydroxylamine hydrochloride gave liquid and solid products respectively, whilst that from aniline was partly liquid and partly solid unless subjected to prolonged heating. In presence of basic reagents, *e.g.*, sodium hydroxide or carbonate, or ammonia, condensation did not proceed beyond the formation of black or brownish black plastic masses, *m.p.* ca. 150° C., completely soluble in organic solvents, from which they separated as a varnish. The preliminary stages of condensation also occurred at high temperatures in the absence of catalysts. The liquid condensation products, which may be prepared *in situ*, can be used to render paper, or textiles, waterproof and electrical insulators. The solid products adhere firmly to metallic surfaces, but they are only imperfect insulators, although aniline hydrochloride under certain conditions furnishes a product satisfactory in this respect. The material also proved more durable than leather for footwear. Unsatisfactory results were obtained by the use of mixtures of furfuraldehyde and formaldehyde or benzaldehyde, or of benzaldehyde or salicylaldehyde alone, in conjunction with phenols. Furfuraldehyde has not the same hardening and destructive effect on micro-organisms or albuminoid substances as formaldehyde, and is therefore of little value as a steriliser, or for hardening photographic plates or for tanning purposes.—J. K.

PATENTS.

Carbon black; Apparatus for producing —. F. E. Paterson. U.S.P. 1,314,060, 22.6.20. Appl., 21.11.19.

NATURAL gas is burnt in a series of burners, the flames from which impinge on outwardly and upwardly branching plates supported over the burners. The carbon black deposited on the plates is detached by moving them against scrapers, which discharge it into a hopper with inclined sides and a trough at the lower end, through which a conveyor passes.—A. R. P.

Soluble constituents of materials [e.g., resin, montan wax]; Process for extracting —. H. Bollmann. G.P. 320,543, 10.8.18. Addn. to 303,846.

THE process described in the chief patent (J., 1920, 459 A) is suitable for extracting other materials, *e.g.*, resins from vegetable matter or montan wax from lignite.—L. A. C.

Resin solutions; Manufacture of clear —. Deutsch-Luxemburgische Bergwerks- und Hütten A.-G., and S. Hilpert. G.P. 319,011, 12.5.16.

RESIN obtained by heating with water, without carbonising, the waste sulphuric acid from benzol hydrocarbon purification, is extracted with benzene hydrocarbons. The solution is separated from the dilute sulphuric acid, and may be added direct to resin varnishes, *e.g.*, coumarone varnish, or the solvent may be removed, in which case the product is obtained as a bright yellow powder.—L. A. C.

Varnish; Manufacture of a quick-drying — from tar products. Deutsch-Luxemburgische Bergwerks- und Hütten A.-G., and S. Hilpert. G.P. 319,010, 28.4.16.

A VARNISH contains coumarone resin, the organic matter separated without charring from sulphuric acid used in the purification of benzol hydrocarbons, and a drying fatty oil, with or without a solvent.—L. A. C.

Sheet material for use in making printing plates and matrices. J. S. Stokes. E.P. 145,123 and 145,124, 20.3.19.

MATRICES for the production of printing plates con-

sist of a fibrous backing faced with a non-fibrous material as metallic foil or a phenolic condensation product (from phenol and formaldehyde) hardened by heat. The backing is impregnated just short of saturation with a phenol condensation product capable of becoming hard and set under heat and pressure. It is capable of absorbing moisture, thereby becoming flexible.—A. J. H.

Celluloid or vulcanite substitutes. E.P. 145,128. See V.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Permeability of — to gases. J. D. Edwards and S. F. Pickering. Chem. and Met. Eng., 1920, 23, 17—21, 71—75.

THE experimental procedure was that of the U.S. Bureau of Standards; pieces of balloon fabric were exposed at 25° C., on one side to air at a pressure of 760 mm. of mercury and on the other to the gas under examination at an excess pressure of 30 mm. of water; the amount of transfused gas was usually estimated by the interferometer. A decrease in permeability is observed with the ageing of the rubber film and with an increased degree of vulcanisation, the effect in the former case possibly being due to the lower permeability of resinous oxidation products. With different pressures the permeability is proportional to the partial pressure of the gas, and it is possible to correct all results to a standard partial pressure of 760 mm. of mercury. The resistance of a rubber film to the passage of a gas increases with its thickness, and the specific permeability of rubber can be calculated; the greater resistance of a given weight of rubber when spread on cloth is to be attributed to the greater effective thickness of the rubber layer. Using the Shakespear catharometer it is found that the actual time required for penetration is very small. There is no obvious simple relation between the permeability and the temperature for any gas, but the relative increase with rise of temperature is approximately the same in all cases. The specific permeability of vulcanised rubber, representing the volume of gas at a partial pressure of 760 mm., which would pass across a centimetre cube in one minute at 25° C., is found to approximate to 20.4×10^{-6} for hydrogen (cf. Kayser, Wied. Ann., 1891, 43, 544). Taking hydrogen as a standard and making comparisons with it at the same partial pressure, the following values are obtained for the relative permeability of the respective gases and vapours:—Oxygen, 0.45; nitrogen, 0.16; air, 0.23; carbon dioxide, 2.91; helium, 0.65; ammonia, 8.0; methyl chloride, 18.5; ethyl chloride, approx. 200; water vapour, approx. 50. For water the value is almost twice as great if liquid water is in contact with the rubber.

—D. F. T.

Rubber; Direct method for the determination of rubber hydrocarbon in raw and vulcanised —. W. K. Lewis and W. H. McAdams. J. Ind. Eng. Chem., 1920, 12, 673—676.

UNVULCANISED rubber is extracted overnight with acetone, dried, dissolved in carbon tetrachloride, and the solution filtered. An aliquot portion of this solution, containing about 0.2 g. of rubber hydrocarbon, is treated with an excess (130%) of bromine dissolved in carbon tetrachloride and, after the mixture has stood for 3 hrs. in the dark, the excess of bromine is determined iodometrically. Ten c.c. of 5% potassium iodate solution is then added and the iodine liberated due to the hydrogen bromide formed by substitution is titrated. Twice the number of c.c. of thiosulphate solution used in the second titration is deducted from the number used in the first, and the result is subtracted from the volume of thiosulphate required for the titra-

tion of the bromine solution without rubber. The equivalent of rubber hydrocarbon ($C_{10}H_{16}$)_x, is 34. In the case of vulcanised rubber, 2 g. of the sample is extracted with acetone for 6 hrs., dried, extracted under a reflux condenser with 100 c.c. of tetrachloroethane for 4 hrs., the mixture cooled, diluted to 250 c.c. with carbon tetrachloride, and a portion of this solution treated as described. It is shown that the so-called "combined sulphur" is actually combined with the double bonds of the rubber hydrocarbon.—W. P. S.

PATENTS.

Rubber and rubber-like materials; Processes for reclaiming — from fabrics coated therewith. E.C. R. Marks. From Acushnet Process Co. E.P. 145,254, 16.6.19.

XV.—LEATHER; BONE; HORN; GLUE.

PATENTS.

Pelts; Removing lime from and tanning —. Chem. Fabr. Rosenberg und Co. G.P. 320,301, 9.11.18.

THE pelts are treated with a solution, diluted with water, of condensed lime-free neutral or acid sulphite-cellulose waste lye in glycerin still-residues. —L. A. C.

Glue; Manufacture of a substitute for —. Farbenfabr. vorm. F. Bayer und Co. G.P. 318,957, 8.7.13.

SOLUBLE starch produced by the action of acids on starch is heated with formaldehyde in the presence of water. A colourless solution equal in adhesive power to a solution of animal glue of the same concentration is obtained; on drying the solution a colourless residue is formed which first swells and then goes gradually into solution when added to water. The product may be used as a substitute for animal glue, or as a size or thickener in printing textiles.—L. A. C.

XVI.—SOILS; FERTILISERS.

Plant growth and pigmentation; Effect of coloured light upon —. Precipitation of paint pigments under coloured light. H. A. Gardner. U.S. Paint Manufs.' Assoc., Circ. 98, 5 pp.

PRELIMINARY experiments indicate that the colour of the light under which plants are grown has some influence on the plant growth and chlorophyll formation. A purple-blue tone seemed to be most injurious. There is some indication that pigments precipitated under differently coloured lights may exhibit slight differences in tone.—W. G.

Soils; Acidity and acidimetry of —. III. Comparison of methods for determining lime requirements of soils with hydrogen electrode. IV. Proposed method for determination of lime requirements of soils. H. G. Knight. J. Ind. Eng. Chem., 1920, 12, 559—562.

THE vacuum method (heating the soil with finely divided calcium carbonate under reduced pressure) and the hydrogen electrode method are the most trustworthy for determining the lime requirements of soils, but in the latter method the soil must be shaken with lime for more than 3 hrs. For measuring the reduction of acidity in limed soils the Hopkins (cf. Hopkins and Pettit, J. 1920, 461 A) and the hydrogen electrode methods yield the most concordant results. A method proposed for deter-

mining the power of soil to decompose calcium carbonate consists in boiling 10 g. of the soil and an excess of calcium carbonate with 25 c.c. of neutral sodium or potassium chloride solution for 10 mins. and measuring the volume of the liberated carbon dioxide.—W. P. S.

Soil extracts; Solid phases obtained by the evaporation of certain — M. S. Anderson and W. H. Fry. *J. Ind. Eng. Chem.*, 1920, 12, 663—669.

THE salts obtained by the evaporation of aqueous soil extracts have a complex character, and resemble those produced by the natural or artificial evaporation of sea water. No soil, however, furnishes all the salts occurring in natural deposits of saline substances, since the latter represent crystallisation from a composite soil extract. Complex salts begin to separate from a water extract at a point not far from the concentration of air-dry soil, and hence the roots of growing plants may be in contact with solutions of these salts. It is thus probable that the complex salts may be present in the soils only in solution in soil moisture and never in the solid phase.—W. P. S.

Potassium of greensand; Effect of manure-sulphur composts upon the availability of the — A. G. McCall and A. M. Smith. *J. Agric. Res.*, 1920, 19, 239—256.

THE results obtained with two greensands containing 5.88% and 1.42% K respectively indicate that the composting of greensand with sulphur and manure may prove to be a practical and efficient method for obtaining available potassium from its comparatively insoluble minerals. The composts containing the largest proportion of manure developed the highest degree of acidity, oxidised the greatest amount of sulphur, and produced the largest amount of water-soluble potassium. In such composts the total amount of potassium recovered in the water extracts after twenty-three weeks varied from 9.1% to 41.3% of the total amount initially present. The addition of small amounts of ferrous sulphate or aluminium sulphate did not stimulate sulphofication. Calcium carbonate, though acting as a stimulant in the early stages, did not increase the soluble potassium obtained.—W. G.

Nitrate-nitrogen and nitrates in fertilisers; Determination of — H. C. Moore. *J. Ind. Eng. Chem.*, 1920, 12, 669—673.

TO determine total nitrogen in fertilisers containing nitrates, 0.8—1.7 g. of the sample is shaken for 15 mins. with 35 c.c. of sulphuric acid containing 1 g. of salicylic acid, 5 g. of sodium thiosulphate is then added and the mixture heated until frothing ceases. After the addition of 5 g. of potassium or sodium sulphate and 0.5 g. of mercury, the mixture is heated until a clear solution is obtained, and the heating is then continued for a further 90 mins. Sodium sulphide is added in the subsequent distillation of the ammonia formed.—W. P. S.

Field heterogeneity; Practical universality of — as a factor influencing plot yields. J. A. Harris. *J. Agric. Res.*, 1920, 19, 279—314.

Fertilisers; Manufacture of — containing phosphoric acid and alkali nitrates. E. Reinau. G.P. 301,703, 17.2.16. Addn. to G.P. 299,001 and 299,007 (J., 1920, 449 A).

THE mother liquors, wash waters, or distillation residues obtained by the treatment described in the original patents are allowed to interact with tertiary phosphorite, the product being then dried if desired (cf. J., 1920, 461 A).—W. J. W.

Lime-polash fertiliser; Process of producing — from polash-bearing minerals and lime. R. Do Luce. U.S.P. 1,315,077, 29.6.20. Appl., 9.4.20.

A MINERAL containing potassium is mixed with more than its own weight of powdered calcium oxide, and the mixture is passed into a pressure tank by means of superheated steam.—J. H. J.

Crude calcium cyanamide; Continuous manufacture of — A. Lang. G.P. 319,798, 21.11.17.

NITROGEN, previously heated to the reaction temperature, is passed into a nozzle containing finely divided calcium carbide, and the mixture is then blown under pressure into a reaction chamber.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Two-masseuite system of boiling used in Hawaii. R. C. Pitcairn. *Facts about Sugar*, 1920, 10, 230—231.

A SYSTEM of boiling has been adopted in Hawaii according to which two masseuites are produced in order finally to obtain an unrefined sugar polarising about 96°, and exhausted molasses. During the boiling of the first or high-grade, the purity of the syrup coming from the evaporators is lowered to about 72°—73° by the addition of unexhausted molasses, and on centrifuging this masseuite a sugar having the polarisation stated and a molasses having a purity of 48°—50° are obtained. The second or low-grade masseuite is made up with syrup, molasses of 48°—50° purity, and some re-melted low-grade sugar, these being added in proportions to give a purity of about 50°. A temperature of 140° F. (60° C.) is used in boiling this low-grade pan, the contents of which are cooled slowly to 130° F. (54° C.) before discharging. On centrifuging the resulting masseuite, a molasses having a purity about 30° (which is exhausted) and a low-grade sugar are obtained, the latter being either re-melted for the low-grade pan, or used for "seed" in boiling the first masseuite.—J. P. O.

Chemical control figures for the 1919 Java sugar crop. H. C. Prinsen Geerligs. *Intern. Sugar J.*, 1920, 22, 318—325.

DURING 1919 the cane harvested was 38.10 tons per acre, and the sugar extracted was 10.06%, which values are smaller than any recorded since 1915, owing chiefly to the dry weather prevailing and to the lack of fertilisers. Chemical control figures for 1919 and 1918 were: sucrose in the cane, 12.38, 13.63; fibre in the cane, 13.01, 12.99; sucrose in the bagasse, 4.01, 4.34; water in the bagasse, 47.01, 47.22; mill extraction, 92.0, 92.1; sucrose in the press-cake, 3.7, 4.36; and calculated available sugar, 10.60, 12.17%. On 100 parts of sucrose originally present in the cane, the sucrose lost during manufacture was due to that remaining in the bagasse, 7.99; that left in the press-cake, 0.49; that unextracted from the molasses, 7.27; and that unaccounted for, 2.59, a total of 18.34%. Other values for 1919 and 1918 respectively are: purity of the raw juice, 83.7, 86.5; and the purity of the final molasses, 32.1, 33.1. From figures for a number of different factories it appears that there is no relationship between the purity of the juice and that of the final molasses, nor does the method of clarification (defecation, sulphitation, or carbonatation) seem to exert any marked influence on the desaccharification. This is substantiated further by the values for the sugar actually obtained per 100 of the calculated available amount, which averaged 97.4, but was 97.6 for the defecation process, 97.1 for sulphitation, and 97.4 for carbonatation. Of the total output of sugar in Java in 1919 the plantation white was 51.8, refining assortments (11—20 D.S.) 46.4%, and the rest

"sack" and molasses sugars. About 96,500 tons of solidified molasses (which is chiefly exported to India for alcohol production) was also made during the period under review.—J. P. O.

Reducing sugars; Determination of — by the volumetric permanganate method. T. van der Linden. *Archief Suikerind. Nederl.-Indië*, 1917, 25, 325—327. *Intern. Sugar J.*, 1920, 22, 413.

In order to avoid any error that may arise owing to atmospheric oxidation in Bertrand's method (J., 1907, 60; 1919, 381 A), it is recommended that the cuprous oxide should be dissolved in an unacidified solution of the ferric salt used, the sulphuric acid being added immediately before proceeding to the titration with standard permanganate solution.

—J. P. O.

Reducing sugars; Iodometric determination of —. H. van Nouhuys. *Archief Suikerind. Nederl.-Indië*, 1920, 28, 591—595. *Intern. Sugar J.*, 1920, 22, 411—412.

SCHOORL'S modification of the iodometric method should be operated as follows, the quantity of sulphuric acid stated in the description given by Geerlings and Tervooren in their "Handboek" (3rd ed., p. 95-96) being too small: 30 g. of the product is clarified with 25 c.c. of normal lead acetate (30%), made up to 500 c.c., and filtered; 100 c.c. of the filtrate is treated in a 500 c.c. flask with sufficient sodium phosphate solution to precipitate all the lead and calcium present, after which the liquid is made up to 500 c.c. and filtered. Following the procedure described by Herzfeld, 50 c.c. of this filtrate and 50 c.c. of Fehling's solution are boiled together; at the end of the 2 min. specified the reaction is checked by the addition of 100 c.c. of cold water (recently boiled), and the whole cooled; 7.5 g. of potassium iodide and 25 c.c. of 25% sulphuric acid are successively added, the iodine liberated being titrated with N/10 thiosulphate. Compared with Bertrand's permanganate method (J., 1907, 60; 1919, 381 A), this iodometric modification gives slightly lower results. It is recommended as a rapid procedure, convenient for routine practice.

—J. P. O.

Sugar; Delicacy of the α -naphthol test for the presence of traces of —. M. Kauffman. *Archief Suikerind. Nederl.-Indië*, 1920, 28, 515—519. *Intern. Sugar J.*, 1920, 22, 412.

In testing for the presence of traces of sugar in the waters condensed from evaporators and pans by means of α -naphthol, the procedure involving underlaying with sulphuric acid is generally followed in the sugar factory. A more delicate and certain indication is stated to be obtained by the Skärblom modification, in which one or two drops only of the water under examination are mixed with about 0.2 c.c. of a 4% alcoholic solution of α -naphthol and about 1 c.c. of concentrated sulphuric acid, and the whole shaken together. Whereas this modification was found to be capable of detecting 0.0005 g. of sugar per litre, the method generally followed failed to show the presence of 0.015 g. It is said the delicacy of the underlaying method depends much upon the manner in which the sulphuric acid is added to the sugar solution. Thus, if the acid is added very slowly so as to minimise mixing, the ring may be hardly visible; whereas in the case of a solution of lower sugar content, if the test-tube be shaken a little after the addition of the acid a distinct colour will be obtained.—J. P. O.

Tint photometer for sugars. Meade and Harris. See XXIII.

Drying residues of starchy mosses. G. P. 320,375. See IIA.

XVIII.—FERMENTATION INDUSTRIES.

Yeast fermentation; Sulphurous acid and —. E. Hägglund. *Biochem. Zeits.*, 1920, 103, 299—306.

SULPHUROUS acid at 0.007-N concentration completely inhibited the fermentation of 1 g. of yeast in 25 c.c. of solution; 0.005-N acid did not completely inhibit the fermentation. The toxic effect of sulphurous acid on yeast fermentation is attributed to the undissociated acid. Sodium sulphite showed an inhibitive action as compared with potassium sulphate. A 0.2-N potassium sulphate solution increased the fermentation by about 25%.

—S. S. Z.

Diastatic power; Volumetric method for the determination of —. J. T. Flohil. *J. Ind. Eng. Chem.*, 1920, 12, 677.

ONE c.c. of a 5% malt solution (prepared according to Lintner's method) is added to 100 c.c. of 2% soluble starch solution, the mixture is kept at 20° C. for 1 hr., 10 c.c. of N/10 sodium hydroxide solution added, and the whole diluted to 200 c.c.; 25 c.c. of this solution, 20 c.c. of Fehling's solution, and 5 c.c. of water are boiled together for 2 mins., cooled to 25° C., 3 g. of potassium iodide and 10 c.c. of 25% sulphuric acid are added, and the liberated iodine is titrated with thiosulphate solution. The amount of cupric salt reduced by the hydrolysed starch is calculated into Lintner degrees.

—W. P. S.

Alcohol-testing device. S. Waldbott. *J. Ind. Eng. Chem.*, 1920, 12, 690.

FIFTY c.c. of the alcoholic liquid is boiled in a flask provided with a column filled with glass beads and a short bent tube at the top of the column, and the alcohol vapour escaping from the open end of the bent tube is ignited. The duration of the flame indicates the alcoholic strength of the liquid.

—W. P. S.

PATENTS.

Distillers' slop; Process of treating —. H. P. Bassett. U.S.P. (A) 1,344,850 and (B) 1,344,851, 29.6.20. Appl., 12.7.19.

(A) DISTILLERS' slop is treated with the hydroxide of an alkaline-earth metal, then acidified, and the volatile fatty acids precipitated by the addition of a salt of a metal which forms insoluble basic salts with them. The liquid is then neutralised and the glycerin separated. (B) Formic and acetic acids are removed before precipitation.—J. H. J.

XIXA.—FOODS.

Frozen fish in storage for short and long periods; Chemical study of —. E. D. Clark and L. H. Almy. *J. Ind. Eng. Chem.*, 1920, 12, 656—663.

FROZEN fish remained palatable and wholesome for 13—16 months when kept at 15° F. (−9° C.) provided that they were glazed or coated with ice; paper wrappings afforded but little protection against loss of moisture. After 2 years' storage all the fish became unpalatable. Generally there was a decrease in the water-soluble and coagulable nitrogen, whilst the amino-acid nitrogen also increased slightly; in some cases the proteose nitrogen decreased. Ammonia and amino nitrogen increased considerably in certain species of fish stored in a glazed condition. The acid value of the extracted fat increased whilst the iodine value decreased.

—W. P. S.

Copra meal; Biochemical study of —. F. O. S. y Alvarez. *Philippine J. Sci.*, 1920, 16, 181—189.

A SAMPLE of Manila copra meal from which most of the oil had been extracted contained: Moisture,

11.3; oil, 12.2; crude proteins, 20.1; ash, 5.5; crude fibre, 13.2; and carbohydrates 37.0%. Compared with cotton seed meal it was richer in amides (15.35% of the N) and cystine (3.93%), poorer in arginine, lysine, and non-amino N, whilst the humin N (2.90%) and mono-amino N (25.04%) were about the same. Alkali-soluble protein is the principal protein in copra meal; 47.55% of the protein nitrogen is soluble in hot water. In admixture with green leaves copra meal is an excellent feeding stuff.—C. A. M.

Jelly. C. H. Campbell. J. Ind. Eng. Chem., 1920, 12, 558—559.

In making apple jelly the pectin content of the apple juice should be 1—1.25% and the acidity (expressed as H_2SO_4) 0.3%; 5—6 lb. of sugar is required per gall. of juice. Excess of sugar produces a soft jelly, whilst an insufficient amount gives a tough product. The pectin content is determined by adding 10 c.c. of the filtered juice drop by drop to 180 c.c. of alcohol, collecting the precipitate at once, and drying it for 2 hrs. at 70° C. *in vacuo*. After being weighed, the precipitate is incinerated and allowance made for the amount of ash present. (Cf. Barker, J., 1918, 213 T.)—W. P. S.

Rice. Hofmeister. See XX.

PATENTS.

Atomising and drying milk or other liquids; Apparatus for —. Chemische Verwertungs-Ges. m.b.H. G.P. 320,200, 17.6.19. Addn. to G.P. 311,471 (J., 1919, 694 A).

The milk inlet pipe is surrounded by another pipe, conveying dry air, which is discharged horizontally so as to mix intimately with the atomised material. A second pipe conveying dry air is fixed below the atomising device.—J. S. G. T.

Oranges; Art of treating —. M. Henius, Assr. to F. Mendelsohn. U.S.P. 1,343,915, 22.6.20. Appl., 15.5.18.

Juice expressed from oranges is treated with sulphurous acid and then pasteurised at 50°—60° C.; about 80 parts of actual SO_2 per million parts of juice should be added.—W. P. S.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Aluminium hydroxide in mechanically filtered —. N. J. Howard and F. Hannan. Canadian Eng., 13.5.20.

In Toronto the water supply is mechanically filtered by the drifting sand method, and alumina is found in the filtered water. Laboratory experiments showed that water treated with one or two grains of alum per gallon, allowed to settle, and filtered through a rapid sand filter always gave a reaction for alumina with the haematoxylin test, even if an equivalent amount of calcium hydroxide had been added. When the treated water was filtered through a layer of six fine filter papers alumina was removed at first, but later passed through. This is attributed to the adsorption of the positively charged hydrosol of alumina by the negatively charged filter paper until the latter charge was neutralised. Treated water which had stood for four months still gave the alumina reaction, but it appeared as if the hydroxide had been converted into an aluminate. In Toronto water the residual alumina has been found to have no corrosive action and to be harmless from a health point of view.—J. H. J.

Carbon dioxide; Determination of solvent — in water. H. Noll. Z. angew. Chem., 1920, 33, 182—184.

In Tillmans and Heublein's method of determining the carbon dioxide having solvent action upon

calcium carbonate (cf. J., 1920, 556 A), any carbon dioxide present in the water as iron bicarbonate is titrated with the free carbon dioxide. Hence 1.1 mg. of CO_2 must be deducted for each mg. of Fe_2O_3 present. In the case of waters free from iron the results for solvent dioxide are most accurate when magnesium and sodium bicarbonates are present in addition to calcium bicarbonate. Iron bicarbonate appears to reduce this solvent action the most, and then calcium, magnesium, and sodium bicarbonates in the order given.—C. A. M.

PATENTS

Sludge and scum; Separation of — from sewage and other liquids. S. H. Adams. E.P. 145,291, 1.8.19.

A SEDIMENTATION tank is provided with an apron roof, sloping longitudinally from near one wall to near the bottom of the opposite wall, and suspended on pivots. The floor of the tank slopes in the opposite direction to the roof, and at its lower side terminates in a sludge channel. Sewage enters at one end of the tank and flows over the roof towards the exit pipe at the opposite end. Solids settling out of the sewage slide down the roof into the lower portion of the tank to the sludge channel. Scum rising from the floor of the tank is directed by the under side of the roof into a scum space at the surface between the top of the roof and the side wall of the tank, from which it is removed over a weir into a scum channel. When used for the activated sludge process the tank is made preferably of circular form, the air inlets being so placed as to impart a revolving motion to the liquid. In this case the exit pipe is placed axially and receives the liquid through perforations along its length. (Reference is directed to E.P. 11,073 of 1903, 10,981 of 1907, and 111,401.)—J. H. J.

Oxygen compounds of sulphur for use as disinfectants, fungicides, and insecticides; Apparatus for manufacture of —. T. A. Clayton. E.P. 141,661, 1.10.19. Conv., 11.4.19.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Digitalis leaf extracts; Stability of —. The infusion. II. C. A. Pomeroy and F. W. Heyl. Amer. J. Pharm., 1920, 92, 391—401. (Cf. J., 1919, 654 A.)

The aqueous infusion of digitalis is slightly less active than the tincture of equal concentration. The infusions deteriorate on keeping at the rate of about 20% in 3—4 days in warm weather, and in 7 days in cold weather (10° C.), and should accordingly be discarded at the expiration of these periods. The addition of alcohol does not increase the stability.—G. F. M.

Rice polishings; Alkaloid constituents of —. F. Hofmeister. Biochem. Zeits., 1920, 103, 218—225.

AN alkaloid substance, termed "oridine," was extracted from rice, which showed antineuritic activity and which on further purification became inactive. It is isomeric with betaine and valine, and is supposed to be related to the pyridine and piperidine groups. (Cf. J.C.S., i., 586.)—S. S. Z.

Turpentine from Pinus longifolia Roxb.; Constituents of Indian —. J. L. Simonsen. Chem. Soc. Trans., 1920, 117, 570—578.

By repeated fractional distillation of Indian turpentine three main fractions were isolated. The lowest fraction, b.p. 155°—167° C. at 706 mm., consisted mainly of α - and β -pinene. The second fraction eventually gave an oil boiling constantly at 165°—169° C. at 705 mm. consisting of a new

bicyclic terpene, sp. gr. 0.8586 at 30° C., $n_D^{20} = 1.469$, $\alpha_D = +7.69^\circ$, to which the name *d*-carene is given. It is readily oxidised by air, gives a crystalline nitrosate, and is converted by hydrogen chloride in dry ether into a mixture of the hydrochlorides of *d*-sylvestrene and dipentene. From the products of its oxidation by Baeyer and Ipatiev's method (Ber., 1896, 29, 2796) *trans*-caronic acid was isolated, and it is considered that the terpene contains a carane ring, and that it is either Δ^3 - or Δ^4 -carene. From the highest fraction of the distillation of the original turpentine the sesquiterpene *d*-longifolene was isolated as a colourless, somewhat viscous oil, b.p. 254°–256° C. at 706 mm., sp. gr. 0.9284 at 30° C., $n_D^{20} = 1.495$, $\alpha_D = +42.73^\circ$. It yields no solid nitrosate, but gives a beautifully crystalline hydrochloride, hydrobromide, and hydriodide.—G. F. M.

Phytin in plant extracts; Determination of —. A. Rippel. Biochem. Zeits., 1920, 103, 163–172.

PHYTIN can be precipitated more or less quantitatively in the presence of inorganic phosphates by copper acetate in acetic acid solution. Favourable results can only be obtained with definite concentrations of copper acetate and acetic acid. An extract from barley yielded 63.3% of the phytin P_2O_5 by precipitation with copper acetate in 1% acetic acid. The same method accounted for 92.8% of the phytin in standard solutions of that substance. The phytin in an acetic acid extract from peas could not be precipitated by copper acetate at all.—S. S. Z.

Anemonine; Synthesis and constitution of —. Y. Asahina and A. Fujita. Yakugakuzasshi, 1920, 455. J. Pharm. Chim., 1920, 22, 22–26.

RANUNCULUS oil, on reduction with sodium amalgam and acetic acid in methyl alcoholic solution, gave only an insignificant amount of dihydroanemonine, the main product being the lactone of angelic acid, which was identified by conversion into the semicarbazone of levulinic acid. The chief constituent of the oil is therefore not anemonine but a substance which is converted into angelic lactone by reduction, and into anemonine by the spontaneous condensation of two molecules, and to which the name protoanemonine is given. Formulæ are suggested for protoanemonine, and for anemonine, which were confirmed by the synthesis of anemonine from β -bromolevulinic acid, and also from the dibromide of angelic acid lactone.—G. F. M.

Mercury. François. See XXIII.

PATENTS.

Lecithin; Process of recovering — from animal and vegetable substances. C. Baumann and J. Grossfeld. E.P. 144,895, 11.7.19.

LECITHIN is recovered from animal and vegetable substances, such as egg yolk or fish roe, or from raw commercial lecithin before the separation of the fat, cholesterol, etc., by dissolving the substances in an organic solvent such as methyl alcohol, and treating the solution with hydrogen in presence of a hydrogenating catalyst, for example, palladium or nickel, until little or no lecithin can be extracted from the mixture by cold ethyl acetate. By this means the lecithin is saturated first, and the hydrogenation is stopped at this stage before the fats are attacked. The residue after the evaporation of the solvent, is dissolved in hot ethyl acetate, and on cooling the solution the lecithin is almost quantitatively precipitated in a technically pure condition.—G. F. M.

Acetaldehyde from acetylene as primary material; Catalyst for the manufacture of —, and process of regeneration of the catalyst. Soc. des Acières et Forges de Firminy. E.P. 124,194, 18.2.19. Conv., 13.3.18.

AN improved catalyst for the hydration of acetylene consists of a solution of sulphuric acid containing mercury, ferric, and vanadium salts, which after becoming exhausted can be regenerated by electrolytic oxidation either intermittently or continuously, using a cell with a magnetite or platinum anode and a current density of 3–5 amps. per sq. dm., the temperature being maintained at 30°–40° C. As an example, the catalyst may consist of a solution containing 10–20% of sulphuric acid, 2% of mercury, 0.3–0.5% of iron, and 0.025–0.1% of vanadium, the metals being present as sulphates. This bath is maintained at about 65° C., and up to 1 ton of aldehyde can be produced with 2 cb. m. of catalyst before the reaction slows down. For the electrolytic regeneration it is not necessary to interrupt the process and transfer at once the whole of the catalyst to the cell, but a fraction of the catalytic liquid in circulation may be withdrawn by means of a branch pipe and made to traverse the electrolytic cell, whereby continuous regeneration is effected.—G. F. M.

Ethylene oxide; Preparation of —. Badische Anilin- u. Soda-Fabrik. G.P. 299,682, 11.4.15.

IN the preparation of ethylene oxide much better results are obtained if, instead of adding ethylene chlorhydrin to warm caustic alkali solutions, bases are added to warm ethylene chlorhydrin or its solutions. By this means the tendency to glycol formation is minimised.—G. F. M.

Carboxyl groups; Elimination of —. [Production of phenols.] J. E. Marsh. E. P. 144,897, 14.7.19.

THE elimination of the carboxyl group from organic acids, particularly hydroxy-aromatic acids, such as gallic acid, is effected by heating the acid with a dry metallic salt, preferably an alkali halide. The reaction is advantageously carried out under reduced pressure, and if the product is volatile its recovery is effected in the same operation by distillation, the decomposition being conducted in a vacuum still. For example, pyrogallol in a technically pure condition is obtained by distilling a mixture of gallic acid with half its weight of sodium chloride at a temperature of 250° C. and a pressure of 10 mm. The yield amounts to 95% of the theoretical.

—G. F. M.

Ureas; Manufacture of asymmetric —. A. V. Blom. E.P. 125,584, 17.3.19. Conv., 17.4.18.

ASYMMETRIC ureas are produced by the interaction of phosgene with aminonaphtholsulphonic acids and primary aromatic diamines in presence of alkalis or alkali carbonates. The aromatic diamine must contain two primary amino groups having different reaction speeds, one either being protected by an ortho substituent as in the toluylenediamines, or else being formylated. The two components are brought together, in molecular proportions, continuously into reaction with the calculated quantity of phosgene in a large stirring vat at 40° C., whilst the alkali solution is allowed to run in in sufficient quantity immediately to neutralise the hydrogen chloride liberated during the reaction.—G. F. M.

Arsine derivatives; Preparation of —. A. Job and H. Guinot. E.P. 144,806, 18.3.19.

NITRILES of the general formula R_2AsCN , where R is a fatty or aromatic radicle, are converted into amides and acids of the type $R_2AsCONH_2$ and R_2AsCO_2H by the general methods for the hydration of nitriles. For example, cacodyl cyanide is converted into dimethylarsiniformic acid by boiling it

with about 3 times its weight of 50% sulphuric acid for 12 hrs. The acid is isolated through its calcium or barium salt and crystallised from acetone and alcohol. Diphenylarsinoformic acid may be similarly prepared from diphenylarsino cyanide, or the amide may first be prepared and isolated by treating the cyanide with the theoretical quantity of hydrogen peroxide at 40°–50° C. in alkaline solution and crystallising from alcohol the solid product which separates out. The amide is then converted into the acid by treatment with nitrous acid in the usual way. Diphenylarsinoformic acid is only slightly soluble in water, but most of its salts are very soluble.—G. F. M.

Selenium compounds; Preparation of aromatic —. A. Schoeller. G.P. 319,161, 10.5.19.

AROMATIC selenium compounds are obtained in quantitative yield by the action of the diazonium salts of the corresponding bases on the aqueous solution of polyselenides prepared by triturating or fusing together an excess of metallic selenium with a caustic alkali. It is not necessary to exclude air during the operation as in the case of alkali selenide or hydroselenide solutions. Examples are given of the preparation of diphenylselenide from phenyldiazonium chloride, and diphenyldiselenide and diphenylselenide carboxylic acids from diazotised anthranilic acid. The two acids are separated by oxidation with dilute nitric acid or with hydrogen peroxide, whereby the former is converted into the corresponding selenic acid, and the latter into the lactone of diphenylselenium oxide di-*o*-carboxylic acid. On treatment with cold dilute ammonia only the acid dissolves, and the compounds thus separated are reconverted into the original acids by reduction with zinc dust in alkaline solution.

—G. F. M.

Chlorosulphamides; Preparation of —. M. Claass. G.P. 318,899, 31.12.18.

THE stability of aromatic chlorosulphamides is increased by the introduction of a carboxyl group. The new compounds may be prepared by the usual methods and are useful germicides. The dichlorosulphamide of benzoic acid, prepared from *p*-sulphaminobenzoic acid and alkali hypochlorite solution by acidification with acetic acid, melts at 203° C. The monochloro compound, formed in small quantities in the same reaction, melts at 223° C.

—G. F. M.

Alcohols; Preparation of polyhydric —. O. Matter. G.P. 299,074, 19.4.16.

POLYHYDRIC alcohols are obtained by saponification of the corresponding halogen substituted hydrocarbons by means of aqueous solutions of carbonates, bicarbonates, or mixtures of the two, preferably in a closed vessel to prevent the escape of carbon dioxide. If the caustic alkali is added periodically or continually the saponifying agent is continually regenerated, and its concentration maintained; the velocity of the reaction is thereby considerably increased. Examples are given of the preparation of ethylene glycol from ethylene dichloride and sodium carbonate or bicarbonate at 130°–140° C.

—G. F. M.

Tropinonecarboxylic acid esters; Manufacture of —. R. Willstätter. G.P. 302,401, 27.1.17.

N-METHYLPYRROLEDIACETIC acid esters, prepared as described in G.P. 300,672 (J., 1920, 385 A), on reduction with hydrogen and platinum in acetic acid solution yield N-methyltetrahydropyrrolediadic acid esters. The diethyl ester, a thin, colourless oil with an alkaline reaction, has b.p. 162.5° C. (9 mm.), and is soluble in 60–70 parts of boiling water; the dimethyl ester has b.p. 155.5° C. (12 mm.), and is soluble in 6–7 parts of boiling water. By the action of sodium, sodium

alcoholate, or sodamide, N-methyltetrahydropyrrolediadic acid esters are converted into tropinonecarboxylic acid esters. The ethyl ester is difficult to separate from mixtures with other organic compounds, very readily decomposes and resinifies, is soluble in water and alcohol, and gives a strong reaction with ferric chloride. Tropinonecarboxylic acid ethyl ester on heating with dilute acids yields tropinone, which can be isolated as such, or as the picrate or dibenzal derivative. Reduction by electrolysis or by sodium-amalgam yields *r*-ecgonine ester.—L. A. C.

Acetic aldehyde; Preparation of — from acetylene. A. Guyot, Assr. to Comp. des Prod. Chim. d'Alais et de la Camargue. U.S.P. 1,313,715, 15.6.20. Appl., 5.4.18.

SEE E.P. 21,117 of 1911; J., 1915, 924.

Metacholesteryl. G.P. 318,900—1. See XII.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Colouring matters of flowers; Use of — in colour photography. P. R. Kögel, Phot. Korrr., 57, 86–91. Chem. Zentr., 1920, 91, IV., 60.

SEVERAL of the benzopyrillium compounds occurring in flowers are shown to have a relatively high light-sensitiveness. The anthocyanins which by themselves are light-fast, can be made very light-sensitive by the addition of sensitisers, *e.g.*, *o*-anethol to cyanidin hydrochloride. *o*-Anethol can occur as a degradation product in plants, so that it would appear that these dyestuffs can form their own sensitisers. An objection to the use of an anthocyanin in the bleach-out process is its low covering power.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Dicyanodiamide as explosive. J. Baumann. Chem.-Zeit., 1920, 44, 474.

MIXTURES of dicyanodiamide (1 pt.) with ammonium nitrate (3 pts.), and of dicyanodiamide (1 pt.) with potassium chlorate (3 pts.) had an explosive power (in the lead block test) exceeding that of TNT by 17% and 72% respectively. The ammonium nitrate mixture can be ground without danger, and is particularly suitable for mining purposes.

—C. A. M.

Nitrophenols. Vignon. See III.

PATENTS.

Explosive; Ammonium-nitrate —. W. O. Snelting, Assr. to Trojan Powder Co. U.S.P. 1,313,063, 8.6.20. Appl., 11.1.19.

THE explosive consists of over 40% of ammonium nitrate together with nitrostarch and a finely divided material of high covering power interspersed among the particles of ammonium nitrate.

—T. St.

Explosive; Ammonium-nitrate —. J. B. Bronstein and C. E. Waller, Assrs. to Trojan Powder Co. U.S.P. 1,343,077, 8.6.20. Appl., 5.2.20.

THE explosive consists of a substantially non-explosive mixture of ammonium nitrate and trinitrotoluene with a sufficient amount of a detonating agent to render the mixture explosive.

—T. St.

Nitrostarch; Process of stabilising —. B. J. Flurschein, Assr. to Aetna Explosives Co. U.S.P. 1,343,317, 15.6.20. Appl., 17.5.17. Renewed 5.3.20.

NITROSTARCH is boiled with an aqueous solution of cyanamide, and, after the final wash water has been eliminated, is dried.—T. St.

XXIII.—ANALYSIS.

Filter with wire-gauze layer. F. Mach and P. Lederle. Chem.-Zeit., 1919, 43, 831.

THE platinum gauze used in the filter described previously by the authors (J., 1919, 476 A) may be replaced by silver gauze.—W. P. S.

Iron basins; Use of — in analysis. H. Sertz. Z. angew. Chem., 1920, 33, 156.

IRON basins or crucibles are useful for sulphide fusions where platinum or silver vessels are unsuitable. The iron is attacked but slightly, and its resistance may be increased by treating the vessel with nitric acid.—W. P. S.

Weight burette for gas analysis. E. R. Weaver and P. G. Ledig. J. Amer. Chem. Soc., 1920, 42, 1477—1485.

AN apparatus is described whereby the volume of gas taken into a gas analysis burette and that absorbed by any reagent is measured by weighing the amount of mercury expelled or taken into the burette. Specimen analyses show that the mean error in a single gas absorption is 0.004%, with a maximum error of 0.014%.—J. F. S.

Analysis by fractional distillation. Method of maxima and minima. C. Moureu, C. Dufraisse, and P. Robin. Bull. Soc. Chim., 1920, 27, 523—527.

FOR the separation of mixtures of liquids with boiling-points close together, successive fractional distillations are recommended, the division into fractions being controlled not by the boiling-point, but by maximum or minimum values of physical properties such as the sp. gr., refractive index, viscosity, etc. The rectification is continued, similar fractions being united for further fractionation, until a fraction is obtained which when divided by slow distillation, gives sub-fractions all having identical boiling-points and physical properties. A simple vaseline manometer is described for detecting very slight variations in pressure during distillation, and by means of which a distillation may be interrupted and later readily resumed under the same reduced pressure.—W. G.

Tint photometer; The Hess-Ives — and its use with raw sugars. G. P. Meade and J. B. Harris. J. Ind. Eng. Chem., 1920, 12, 686—688.

THE scale readings of this photometer (J., 1917, 449) do not express directly the relative amounts of colour, and for solutions containing 1, 2, 3, 4, etc., units of material run in powers of the readings for 1 unit, considering the scale readings as decimal fractions. Expressed algebraically, this relationship between the scale readings and the amounts of colour becomes $y = K^x$, where y is any scale reading, K the reading for 1 unit of material, and x the

number of units of material to give the scale reading. To avoid repeated calculations, a table is given showing the units of colour corresponding with each scale reading from 100 to 1. The instrument may be used for determining the colour of raw sugars.

—W. P. S.

Melting-points; Method of avoiding temperature correction in the determination of —. M. François. Bull. Soc. Chim., 1920, 27, 528—536.

A MODIFIED form of the flask generally used as a bath in determining melting-points is described, by means of which the thermometer, including the stem, may be immersed in the liquid of the bath and be heated by the return flow of liquid in the convection current set up by heating the bulb of the flask. By a simple arrangement of mirrors it is possible to read the temperature on the thermometer and observe the material in the capillary melting-point tube simultaneously through one telescope.—W. G.

Boiling-point; Method of determining the — with small amounts of substance. V. Arreguine. Soc. Chim. Argent., 3 (Reprint).

A COMPACT and simple apparatus is described by means of which it is possible to determine the boiling-point of liquids with b.p. below 210° C., with only about 3 mg. of substance. (Cf. J.C.S., Sept.)—W. G.

Specific refraction; Significance of — in analytical chemistry. N. Schoorl. Rec. Trav. Chim., 1920, 39, 594—599.

THE author discusses the limitations of the use of the specific refraction, $(n-1)/d$, values for the identification of an unknown organic compound.

—W. G.

Reactions; Sensitiveness of qualitative —. I. Potassium ions. O. Lutz. Z. anal. Chem., 1920, 59, 145—165.

TESTE of the sensitiveness of various reactions for potassium were made under the same conditions as to temperature (18° C.), time of contact (5 mins.), and volume of potassium chloride solution (5 c.c.); the figures give the minimum concentration of potassium which could be detected:—Perchloric acid, 1:435; phosphomolybdic acid, 1:561; platinum chloride, 1:587; sodium borofluoride, 1:970; aniline silicohydrofluoride, 1:1022; sodium phosphotungstate, 1:2170; phosphotungstic acid, 1:2809; sodium cobaltinitrite, 1:25000; sodium-bismuth thiosulphate, 1:57000; sodium picrate, 1:840; sodium amino- β -naphtholsulphonate, 1:1022; sodium bitartrate, 1:1050. These results may be expressed in weight of potassium, e.g., 1:435 would be 11×10^{-3} g. K per 5 c.c.

Sulphuric acid; Gravimetric determination of —. L. W. Winkler. Z. angew. Chem., 1920, 33, 159—160, 162—163. (Cf. J., 1920, 331 A.)

THE presence of ammonium chloride to some extent decreases the interference of magnesium, zinc, manganese, and other salts on the precipitation of sulphuric acid as barium sulphate. Tables are given which show the corrections to be made for the effect of alkali chlorides on the precipitation. In solutions containing alkali sulphates or magnesium sulphate the sulphuric acid is most accurately determined by adding 1 g. of ammonium chloride and 1 c.c. of N/1 hydrochloric acid to 100 c.c. of the solution, boiling the mixture (a fragment of metallic cadmium is added to ensure smooth boiling), and adding a slight excess of 10% barium chloride solution. The barium sulphate is collected after 18 hrs., washed first with 25 c.c. of cold water, then with hot water, dried at 130° C., and weighed, or the precipitate may be ignited before being

weighed. The weight is corrected from tables to obtain the actual amount of barium sulphate.

—W. P. S.

Phosphoric acid; Estimation of small amounts of — as barium phosphomolybdate in the presence and in the absence of organic phosphorus compounds. S. Posternak. Bull. Soc. Chim., 1920, 27, 507—513, 561—568.

For the estimation of amounts of phosphorus as small as 0.05 mg. the following methods give accurate results. In the absence of organic phosphorus compounds 10 c.c. of the phosphate solution is mixed with 10 c.c. of a 20% solution of ammonium sulphate and 1 c.c. of sulphuric acid; the mixture is heated to boiling, 5—10 c.c. of a 10% solution of ammonium molybdate added, allowed to stand for 15 mins., and the ammonium phosphomolybdate collected, washed with a 5% solution of ammonium nitrate, dissolved in ammonia, and reprecipitated by the addition of a 10% solution of barium chloride. This precipitate is collected, washed with water, dried, ignited at a red heat, cooled, and weighed; it has the composition $4\text{Ba}_2[\text{PO}_4(\text{MoO}_4)_{12}]_3 \cdot \text{Ba}_2\text{SO}_4(\text{MoO}_4)_6$ (1 g. = 0.00739 g. P). In the presence of organic phosphorus compounds the mineral phosphate in 20 c.c. of solution is precipitated at 12°—15° C. in the presence of 10 c.c. of a 20% solution of ammonium nitrate. The precipitate is collected after two hours, and its subsequent conversion into barium phosphomolybdate is carried out as described above. In this case the precipitate has the composition $8\text{Ba}_2[\text{PO}_4(\text{MoO}_4)_{12}]_3 \cdot \text{Ba}_4(\text{MoO}_4)_6$, the factor being 0.00780.—W. G.

Iron; Estimation of — and separation of manganese from iron by nitrosophenylhydroxylamine ammonium (cupferron). E. H. Archibald and R. V. Fulton. Trans. Roy. Soc. Canada, 1919, 13, [iii.], 243—253.

THE cupferron precipitate of iron is slightly soluble in the acid solution from which it is precipitated. The solubility is apparently not affected by the substitution of sulphuric for hydrochloric acid, but is appreciably lowered by addition of ammonium chloride. The precipitate is slightly soluble in the wash-water. If corrections are applied for these solubilities, the determination of iron by this method becomes very exact. Iron can be separated from manganese in a solution containing four times as much manganese as iron, the amount of manganese carried along with the precipitate being inappreciable for most purposes. This amount increases with the acid dilution of the mother liquor. The presence of ammonium chloride to the extent of 5 g. in 100 c.c. of solution is an advantage in this separation.—J. R. P.

Iron; Volumetric determination of — in the presence of hydrochloric acid, phosphorus, oxy-acids, and organic matter. H. D. Richmond and E. M. Ison. Analyst, 1920, 45, 258—260.

To determine iron in pharmaceutical syrups etc. 5 or 10 c.c. of the sample is treated with a few drops of hydrochloric acid and *N*/10 permanganate solution is added until a transitory purple coloration is produced throughout the solution. An equal volume of concentrated hydrochloric acid is then added, a small quantity of sodium carbonate to give an atmosphere of carbon dioxide, and then *N*/10 stannous chloride solution, a drop at a time, until a drop of the mixture gives a blue coloration with ferricyanide solution. The mixture is then titrated with the stannous chloride solution until a drop no longer gives a coloration with thiocyanate solution. 1 c.c. of *N*/10 stannous chloride solution = 0.0056 g. Fe.—W. P. S.

Iron; Determination of small quantities of — as thiocyanate. R. Willstätter. Ber., 1920, 53, 1152—1154.

THE solution under investigation (0.5—1.0 c.c.) is treated with concentrated hydrochloric acid

(0.5 c.c.) and made up to 50 c.c. with freshly prepared ammonium thiocyanate solution (40% or, with larger amounts of iron, 10%). The coloration is matched by standard solutions of iron which are similarly treated. Difficulties are caused by the presence of iron in the purest commercial ammonium thiocyanate and by the instability of ferric thiocyanate in solution. The former is overcome by boiling the thiocyanate solution for a short time, after which it remains colourless on cooling. The latter is due to the gradual reduction of the ferric salt by the thiocyanate, the process not appearing to be catalysed by the ferrous salt formed. (Cf. J.C.S., Sept.)—H. W.

Calcium; Comparison of ten different methods of estimation. G. E. Ewe. Amer. J. Pharm., 1920, 92, 401—410.

CALCIUM was estimated by the following methods in a specimen of calcite containing 0.0407% of impurities (silica, iron, and alumina), the results being expressed as percentages of CaCO_3 :—(1) Precipitation as oxalate and weighing as carbonate, 99.57%. (2) Precipitation as carbonate and weighing as such, 100.07%. (3) Weighing carbon dioxide liberated by hydrochloric acid by absorption in potassium hydroxide solution, 100.03%. (4) Precipitation as oxalate and weighing as oxide, 99.86%. (5) Precipitation as sulphate and weighing as such, 99.68%. (6) Precipitation as oxalate and weighing as sulphate, 100.39%. (7) Precipitation as oxalate and titration with permanganate, 99.68%. (8) Precipitation as oxalate from a slightly acid solution, 99.87%. (9) Weighing by difference carbon dioxide liberated by hydrochloric acid in a Geissler apparatus, 99.80%. (10) Decomposition by excess of standard sulphuric acid and back titration of the excess, 99.75%.—G. F. M.

Mercury in organic compounds; Determination of —. M. François. Bull. Soc. Chim., 1920, 27, 568. (Cf. J., 1920, 280 A).

FOR the deposition of the mercury the following process is recommended: About 0.59% of the dry powdered organic matter is mixed with 30 c.c. of ether, 10 c.c. of alcohol, and 1 c.c. of strong hydrochloric acid, and 1 g. of zinc turnings is added immediately. The mixture is shaken and left for $\frac{1}{2}$ hr., after which another 1 g. of zinc is added, the mixture shaken, and again left for $\frac{1}{2}$ hr. A third 1 g. of zinc is added and the mixture left for 24 hrs. By this time all the mercury is deposited on the zinc, and the estimation is completed as described (*loc. cit.*).—W. G.

Acetic acid in acetates; Method for the determination of —. O. A. Pickett. J. Ind. Eng. Chem., 1920, 12, 570—571.

DISTILLATION with xylene as a carrier for the acetic acid is recommended; 2.5 g. of the acetate is mixed in a distillation flask with 40 c.c. of water, 20 c.c. of 85% phosphoric acid, and 350 c.c. of xylene, and the mixture is distilled until only a thin film of xylene remains on the surface of the phosphoric acid solution. The acidity of the distillate is titrated and allowance made for hydrochloric acid if the acetate contained chlorides.—W. P. S.

*Methyl alcohol; Detection of — by formation of methyl *p*-bromobenzoate.* W. Autenrieth. Arch. Pharm., 1920, 258, 1—14. Chem. Zentr., 1920, 91, IV., 29.

THE formation of crystalline methyl *p*-bromobenzoate (m.p. 77°—78° C.) by the action of *p*-bromobenzoyl chloride with subsequent conversion to *p*-bromobenzamide (m.p. 188° C.) may be employed for the detection of methyl alcohol. Formation of the ester is nearly quantitative, and 0.05 g. of the alcohol can be detected, even if highly diluted. Ethyl *p*-bromobenzoate is a liquid which does not

solidify even at -16° C.; the crystalline methyl ester is formed in an aqueous solution containing 0.2% of methyl and 0.8% of ethyl alcohol; in the case of mixtures of the alcohols, however, it is advisable to increase the proportion of methyl alcohol by fractional distillation, using the first fraction for the test. By this means 0.1 g. of methyl alcohol can be detected in 200 c.c. of urine.

—L. A. C.

Nitro compounds; Examination of — by means of *titanium chloride and sulphate*. C. F. van Duin. Rec. Trav. Chim., 1920, 39, 578—585. (Cf. Callan and others, J., 1920, 86 r.)

In the estimation of nitro-nitrogen by Knecht's method it is recommended to use titanium sulphate instead of the chloride for feebly substituted nitro-compounds. *s*-Trinitrobenzene may be successfully reduced to dinitroaniline by means of titanous chloride. From the results of the reduction of 2,3,4,6-tetranitroaniline and of trinitromethylnitroaminophenol by titanous chloride it is believed that the nitro group in position 3 has the structure $\cdot\text{NO}_2$ and not $\cdot\text{ONO}$.—W. G.

Nitro-groups; Rapid determination of — by a *modification of Young and Swain's method*. L. Desvergues. Ann. Chim. Analyt., 1920, 2, 141—143.

FROM 0.2 to 0.3 g. of the substance is dissolved in alcohol (solution of the substance in sodium hydroxide often gives a yellow coloration which interferes with the subsequent procedure). 100 c.c. of 3% stannous chloride solution and 25 c.c. of hydrochloric acid are added, and the mixture is heated under a reflux condenser for 2 hrs.; a current of carbon dioxide being passed through the mixture during the whole time. The mixture is then diluted to a definite volume and the excess of stannous chloride is titrated in an aliquot portion with iodine solution. The method may be used for a large number of nitro-compounds, but fails in the case of nitrophenols, nitronaphthalenes, and certain volatile compounds.—W. P. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Barbet et Fils et Cie. Recovery of volatile liquids from mixtures with air. 22,888. Aug. 3. (Fr., 1,8,19.)

Bloor. Apparatus for filtering liquids. 22,650. July 30.

Bloxam (Ges. f. Maschinelle Druckentwässerung). Presses for briquetting or drying. 22,748. July 30.

Brutzkus. Apparatus for chemical production and research. 23,039. Aug. 4. (Ger., 4,8,19.)

Buckham, Darnell, and Purvis. Mixing machines. 22,731. July 27.

Fleury and Robertson. Drying apparatus. 22,447. July 28.

Fuller-Lehigh Co. Pulveriser-mills. 22,738. July 30. (U.S., 8,11,19.)

Hinchley. Expressing liquids from materials. 22,880. Aug. 3.

Smallwood. Furnaces. 22,791. July 31. Thompson (Zip Manufacturing Co.) Grinding compounds. 22,321. July 27.

Welter. Producing finely granulated compounds. 22,273. July 26. (Ger., 24,7,19.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,031 (1917). Ges. f. Linde's Eismaschinen. Separating constituents of air or other gaseous mixtures. (147,956.) Aug. 5.

8821 (1918). Barbet et Fils et Cie. Tubular evaporating, condensing, and cooling apparatus. (117,070.) Aug. 11.

2380 (1919). Imray (Jefferies). Cooling and liquefaction of gaseous fluids. (148,588.) Aug. 11.

7871 (1919). General Chemical Co. Apparatus for absorbing gases for a gaseous mixture. (124,761.) Aug. 5.

12,254 (1919). Morris and Haviland. See XI.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Ballantine and Harley. Drying peat etc. 22,248. July 26.

Blair. Treatment of peat. 22,885. Aug. 3.

Bradley. Composition for use as a fuel or building material. 23,053. Aug. 5.

Colmore and Field. Coal substitute. 22,993. Aug. 4.

Corthesy. Distillation of liquid hydrocarbons etc. 22,720. July 30.

Cummins. Gas-retort settings. 22,952. Aug. 4.

Davidson. Destructive distillation of coal etc. 22,487. July 28.

Engelke. Distillation of hydrocarbon oils, asphalts, etc. 22,373. July 27.

Evans, Stanier, and South Metropolitan Gas Co. Removing hydrogen sulphide from gases. 22,585. July 29.

Evans. Destructive distillation of carbonaceous substances. 23,110. Aug. 5.

Farbw. vorm. Meister, Lucius, u. Brünig. Process for desulphurising gases. 22,460. July 28. (Ger. 29,7,19.)

Johnson (Badische Anilin u. Soda Fabr.). Process for desulphurising gases. 23,031. Aug. 4.

MacLaurin, and Scottish By-Products, Ltd. Manufacture of lubricating greases. 22,407. July 28.

Pease. 22,534. See VII.

Tozer. Low-temperature carbonisation and gasification of coal etc. 22,637. July 30.

COMPLETE SPECIFICATIONS ACCEPTED.

3918 (1919). Smith. Furnace retorts. (123,739.) Aug. 11.

8559 (1919). Nielsen. Manufacture of peat fuel. (125,083.) Aug. 11.

13,607 (1919). Campbell. Apparatus for making gas. (148,027.) Aug. 5.

20,697 (1919). Wells. Gas-producers. (148,057.) Aug. 5.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Atack and Robertson. Halogenation of anthraquinone derivatives. 23,113. Aug. 5.
 Cortesey. 22,720. *See* II.
 Engelke. 22,373. *See* II.

COMPLETE SPECIFICATION ACCEPTED.

4278 (1919). Sutton. Sulphonating processes. (147,967.) Aug. 5.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Atack and Robertson. 23,113. *See* III.
 Atack and Soutar. Intermediates and dye-stuffs of anthraquinone series. 23,114. Aug. 5.
 Cowley (Cowley). Dye. 22,457. July 28.

COMPLETE SPECIFICATION ACCEPTED.

10,246 (1919). Maclaurin. Manufacture of dyes. (148,617.) Aug. 11.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bland and Wack. Colouring surfaces of paper, cardboard, etc. 22,396. July 28.
 Bronnert. Manufacture of artificial silk. 22,898 and 23,165. Aug. 3 and 6.
 Bronnert. Production of high-percentage sulphite cellulose. 23,036. Aug. 4.
 Dreaper. Manufacture of artificial silk yarns etc. 22,827. July 31.
 Dreyfus. Manufacture of films, celluloid-like masses, etc. 22,974. Aug. 4.
 Lord, White, and Radcliffe Paper Mill Co. Manufacture of paper etc. 22,971. Aug. 4.
 Meldia Manuf. Co., and Melsom. Dope for balloon fabric etc. 22,574. July 29.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Fanshawe. Finishing fabrics. 22,441. July 28.
 Ferrand and Riley. Apparatus for treating textiles with fluids. 22,969. Aug. 4.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Candlot. Lime, cement, etc. kilns. 22,595. July 29. (Fr., 10,919.)
 Fabry. Obtaining sulphur from hydrogen sulphide. 22,185. July 26.
 Kaltenbach. Manufacture of sulphuric acid. 22,606. July 29. (Fr., 18,220.)
 Leek, Meeze, and Olympia Oil and Cake Co. Manufacture of hydrogen by the iron-steam process. 22,188. July 26.
 Mooney. Manufacture of a solution of chromic sulphate. 23,020. Aug. 4.
 Pease. Extraction of ammonia from gases. 22,534. July 29.
 Pfannenschmidt. Acid chambers, towers, etc. 22,655. July 30. (Ger., 31,719.)
 Reid and Spashett. Concentrating sea-water etc., and recovering salts therefrom. 22,380. July 27.
 Wilton and Wilton. Manufacture of sulphate of ammonia. 23,247. Aug. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

1878 (1918). Marks (Hüttenwerk Niederschöne-weide A.G.). Manufacture and use of cuprous oxide. (147,958.) Aug. 5.
 10,071 (1919). Morel. Production of basic sulphate of chrome and its use in tanning etc. (148,615.) Aug. 11.
 31,908 (1919). Postalozza. Electrolytic apparatus for direct production of hypochlorites. (148,025.) July 5.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Marlow. Gas-fired ovens or kilns for making tiles, pottery, etc. 22,641. July 30.
 Meyer. Grinding or abrading substances. 22,816. July 31. (Ger., 21,119.)

IX.—BUILDING MATERIALS.

APPLICATIONS.

Ambrose. Method of accelerating setting of concrete etc. 22,920. Aug. 3.
 Bean. Manufacture of Portland, Russian, lime, etc. cements. 22,955. Aug. 4.
 Bradley. 23,053. *See* II.
 Candlot. 22,595. *See* VII.
 Planson, and Traun's Forschungslaboratorium Ges. Manufacture of artificial wood etc. 22,825. July 31.

COMPLETE SPECIFICATIONS ACCEPTED.

10,735 (1919). Henderson. Bituminous binders. (148,003.) Aug. 5.
 641 (1920). Smidth & Co. Method of making cement. (137,534.) Aug. 5.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Botten, Gibson, Hounslow, and McRorie. Soldering aluminium. 22,926. Aug. 3.
 Imray (Jackson and Co.). Preliminary treatment of ores or metallurgical products. 22,459. July 28.
 Lavandeyra. Aluminium alloys, and method of making and treating them. 22,562. July 29. (U.S., 7,819.)
 Lévy and Terrisse. Acid-proof castings. 22,907. Aug. 3. (Switz., 27,919.)
 Manchester Furnaces, Ltd., and Russell. Furnaces for heat-treating materials. 22,568. July 29.
 Meakin. Removing oxide from sheet metal. 22,312. July 27.
 Minerals Separation, Ltd., Sellers, and Wood. Ore concentration. 22,763. July 30.
 Tugwood (Dwight and Lloyd Metallurgical Co.). Ore-sintering mechanisms. 23,238. Aug. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

10,333 (1919). Jackson. Production of iron. (147,999.) Aug. 5.
 10,439 (1919). Priest. Muffle and semi-muffle and like furnaces. (148,630.) Aug. 11.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Adam. Electrolysis. 22,214. July 26.
 Adam, Fieldhouse, and Stevenson. Electrolysis. 22,245. July 26.
 Alexander (Stuart Electrolytic Cells, Inc.). Electrode and electrolytic batteries. 22,980. Aug. 4.
 Mull. Utilising mica for electrical purposes. 22,973. Aug. 4.

Smith. 23,201. *See* XIX.
Vesme. Apparatus for producing by electrolysis gas under pressure. 22,260. July 26.

COMPLETE SPECIFICATIONS ACCEPTED.

10,130 (1919). Teixeira. Electric furnaces. (147,988.) Aug. 5.
12,254 (1919). Morris and Haviland. Electrical precipitation of particles from gases. (148,659.) Aug. 11.
22,913 (1919). Kremenezky and Dukes. Galvanic cells. (132,803.) Aug. 5.
31,908 (1919). Pestalozza. *See* VII.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Hough. Manufacture of scouring and emulsifying compounds. 22,677. July 30. (Fr., 26.3.20.)
Nicholson. Apparatus for extracting fats and oils. 22,386. July 27.

COMPLETE SPECIFICATIONS ACCEPTED.

2362 (1919). Dunham. *See* XX.
10,094 (1919). Force. Detergent compound. (125,986.) Aug. 5.
1977 (1920). Verein. Chem. Werke. *See* XVIII.
16,893 (1920). Dunham. Edible oil preparations in dry form. (148,734.) Aug. 11.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Wade (Redmanol Chemical Products Co.). Production of phenolic condensation products. 22,612-3. July 29.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Catalpo, Ltd., and Schidrowitz. Manufacture of caoutchouc etc. 22,491. July 28.
Joannides. Manufacture of dental rubber. 22,881. Aug. 3.
Stewart. Vulcanisation of rubber. 22,503. July 29.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Poppe. Removing grease from skins and hair with recovery of the solvent. 22,282. July 26.
Rautenstrauch. Unhairing skins and hides. 23,019. Aug. 4.

COMPLETE SPECIFICATIONS ACCEPTED.

4571 (1919). Rampichini & Co. Processes based on the action of enzymes for bating hides, and baths, mixtures, etc. for use therein. (124,718.) Aug. 11.
10,074 (1919). Morel. *See* VII.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Broadbridge and Edser. Production of fertiliser. 23,162. Aug. 6.

XVII.—SUGARS; STARCHES; GUMS.

COMPLETE SPECIFICATION ACCEPTED.

1977 (1920). Verein. Chem. Werke. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Fleischmann Co., and Harrison. Production of yeast. 22,374-7. July 27.

COMPLETE SPECIFICATIONS ACCEPTED.

1977 (1920). Verein. Chem. Werke. Manufacture of glycerol from sugar. (138,331.) Aug. 5.
9321 (1920). Jarraud. Ageing spirits and alcoholic liquors. (141,687.) Aug. 5.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Fitzgerald. Preparation of commercial products from blood. 22,751. July 30.
Humphries and Penn. Preserving and sterilising canned fruit etc. 23,239. Aug. 7.
Jones, Watson, and Woodlands, Ltd. Manufacture of flour and bread. 22,267. July 26.
Luca and Petrecca. Preservatives. 22,983. Aug. 4.
Marshall and Sutcliffe. Preparation of edible products and food for animals. 22,962. Aug. 4.
Smith. Electrically treating foods etc. 23,201. Aug. 6.

COMPLETE SPECIFICATIONS ACCEPTED.

10,176 (1919). Namal. Vennoots. Jurgens Vercen. Fabr. Artificial milk products. (128,544.) Aug. 5.
16,893 (1920). Dunham. *See* XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Hewitt. Production of tasteless derivative of quinidine. 23,046. Aug. 5.
Kuh. Production of neutral alkyl esters of sulphuric acid. 22,873. Aug. 3. (Austria, 8.8.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

1600 (1919). Atack and Haworth. Manufacture of aromatic alkylamino compounds. (147,964.) Aug. 5.
2362 (1919). Dunham. Medicinal oil preparations in dry form. (148,587.) Aug. 11.
23,372 (1919). Napp (Hoffmann-La Roche & Co.). Manufacture of complex silver salts of aliphatic amino acids. (148,074.) Aug. 5.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Christensen. Photographic reproduction. 22,760. July 30. (Denmark, 25.3.20.)
Price. Photographic printing. 22,589. July 29.

XXII.—EXPLOSIVES; MATCHES.

APPLICATION.

Marks (Du Pont de Nemours and Co.). Propellant, and process of producing same. 22,711. July 30.

XXIII.—ANALYSIS.

APPLICATION.

Hartridge and Peters. Method of determining acidity or alkalinity of fluids. 22,197. July 26.

I.—GENERAL; PLANT; MACHINERY.

Heat transmission; Effect of air in steam on the coefficient of —. C. S. Robinson. J. Ind. Eng. Chem., 1920, 12, 611–616.

For calculating the coefficient of the transference of heat from vapour to cooling fluid, data are required for the film resistance on the vapour side, the resistance of the metal, and the film resistance on the liquid side. An equation is given for calculating the last-named factor. Curves are also plotted showing the relationship between the film coefficient for condensing vapour and the percentages of steam in mixtures of steam and air, and the effect of air upon the volume percentage of steam and the film coefficient. In the empirical equation a mean value is assumed for the rate of removal of air.—C. A. M.

Colloidal dispersions ["liquid coal" etc.]; Preparation of — on a manufacturing scale. H. Plauson. Chem.-Zeit., 1920, 44, 553–555, 565–567.

About 30 parts of the finely-divided substance is treated with 70 parts of the dispersive agent for a certain time, then diluted with suitable quantities of the agent, thoroughly mixed, and the mixture allowed to stand for 15 mins. to 24 hrs. The supernatant liquid is withdrawn, and the lower layer treated with fresh portions of the agent and again mixed. The liquid then drawn off will behave as a colloidal solution. In Block's "colloid mill" the mixing is effected in globular vessels which revolve eccentrically at an excessively high speed and fling the mixture against baffle bars while, if desired, the vessels may be heated or cooled. By means of this mill the oil may be recovered from crude petroleum sludge; this is emulsified with 80–90% of water, and the oil subsequently separated from the emulsion by heating it at 100° C. In this way 19.8% of petroleum was recovered from a sludge containing 24.6%. Oil may be separated from oil shales, and from oil-cake, filter residues, etc., by emulsification with hot water more effectively than by extraction with solvents etc. For the preparation of "liquid coal" the coal is finely ground and emulsified for $\frac{1}{2}$ to 3 hours in the mill with 60 to 70% of neutral tar oil, peat oil, mineral oil, animal or vegetable oils, etc., at a very high velocity, and for a shorter time if protective colloids are added. Up to 15% of water may be added to the emulsion without causing the coal to separate. "Liquid coal" for Diesel engines must be prepared from wood charcoal or a coal containing not more than 0.8–1.2% ash. The "colloidal mill" may also be used for many other purposes, including the extraction of pure resins, the preparation of fine pigments from coarser kinds of ultramarine etc., and of graphite, and lampblack emulsions, the hydrogenation of oils, and the saponification of fats. Phosphates may be decomposed into a highly-dispersive form in which they are readily absorbed by humic acid. The emulsification may be effected without or with only 1–2% of sulphuric acid.

—C. A. M.

Glass to metal joints. McKelvy and Taylor. See VIII.

PATENTS.

Gas condenser. F. Ryffel. E.P. 124,423, 4.3.19. Conv., 4.3.18.

In a multiple, horizontal, tubular condenser consisting of a series of co-axial tubes, the gas passes downwards through the annular space between the tubes, and the cooling water upwards through the inner tubes. The water collects in a tank which

extends over the top of the tubes, and is distributed over the outside of the outer tubes as spray.

—W. H. C.

Absorbing gases from a gaseous mixture; Apparatus for —. General Chemical Co., Assees. of F. W. de Jahn. E.P. 124,761, 28.2.18. Conv., 3.11.17.

The apparatus is intended more particularly for purifying a nitrogen-hydrogen mixture under high pressure prior to the synthesis of ammonia. The gas at a pressure of about 1400 lb. per sq. in. is washed with water in a coke tower, and then passed through a heater to a gas lift, where it draws in hot caustic soda solution of about 25% strength from a heater. The gas and solution pass to the top of a tower containing pieces of iron and then downward to a tank where the purified gas is separated and passes through a cooling coil to condense water vapour. The separating tank is connected with an overflow tank, and this in turn with a float vessel which controls a discharge valve. The heaters for the gas and the caustic soda are preferably of seamless chromium vanadium steel or tungsten steel. The system provides means for regulating and maintaining automatically a constant level of the absorbing liquid without the use of valves etc. where they would be subject to attack by the liquid.—W. F. F.

Separating liquid mixtures or emulsions; Method of and apparatus for —. J. P. Pedersen. E.P. 125,981, 22.4.19. Conv., 20.4.18.

The liquid to be separated is guided through a circuitous path as an upper layer to a heavier liquid, preferably the pure heavier constituent of the mixture, or as an under layer to a lighter liquid, which may be the lighter constituent of the mixture, by means of a spiral or zig-zag wall that does not extend far into the layers of separated lighter and heavier liquids, so that the main bulk of the liquids after separation remain stationary except for the slow downward or upward flow caused by drawing off the separated liquids continuously through outlets, the level of which may be adjusted. The level of the liquid may also be adjusted (e.g., by means of a float valve) independently of the outlets.—B. M. V.

Catalysis; Processes and apparatus for carrying out chemical reactions by —. Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet et Cartier. E.P. 126,279, 4.4.19. Conv., 3.5.18.

The reacting gases are passed through an insulated tube packed with finely-divided catalytic material, maintained at the requisite temperature by the resistance it offers to the passage of an electric current which is passed through it. No other source of heat is employed. Examples given are the production of acetic acid from acetaldehyde, of ethylene from alcohol, and of acetone from acetic acid.

—W. H. C.

Evaporating liquids [by spraying]; Process of —. G. A. Krause. E.P. 132,256, 2.9.19. Conv., 11.7.17.

In evaporating a liquid by spraying it through air or other drying agent, streams of either external air or of part of the main drying air are directed to the zones of low pressure that would otherwise be caused by the suction of the spraying device and might cause incrustation.—B. M. V.

Evaporators. W. J. Mellersh-Jackson. From The Griscom-Russell Co. E.P. 146,730, 28.7.19.

To keep the levels in a series of evaporators at predetermined heights, the overflow from one evaporator to the next takes place through a narrow slot in a vertical tube contained in an external vessel interposed between the evaporators. The opening of the slot is adjusted by a sleeve which slides up and down the vertical tube and is manipulated from without.—W. H. C.

Stills for the dissociation of chemical solutions by heat; Continuous—R. Fabry. E.P. 146,058, 10.2.20.

PARTLY dissociated liquor (ammoniacal liquor, alkali bicarbonate solution) flows from each tray of a column still through a tubular heat exchanger (where it is heated by the dissociated liquid which flows in series through the heaters) back to the tray next below.—W. H. C.

Drying machines; Rotary cylinder—W. G. and F. R. Simon. E.P. 146,635, 12.4.19.

THE wet material is applied to the heated cylinder or cylinders by one or more unheated cylinders which lift a film of liquid from the feed trough in which it is kept agitated. Any insufficiently dried material is returned to the feed trough.

—W. H. C.

Drying machines. T. Allsop and W. W. Sibson. E.P. 146,744, 3.9.19.

THE goods are placed on a conveyor which takes a circuitous course through a drying chamber, in which air is heated and continuously circulated, the stream of air being divided and guided in various ways so as to cause it to impinge on the goods at various angles.—B. M. V.

Drying apparatus. F. T. Dow. U.S.P. 1,347,473, 20.7.20. Appl., 29.4.19.

MATERIAL is delivered from a hopper on to the lower part of an endless conveyor working in an inclined chamber which is divided longitudinally into two passages. The conveyor is provided with a number of carrier plates which stand out horizontally to receive the material and carry it upwards through the inclined passage. A heating medium is passed through the passage containing the charged carrier plates.—W. F. F.

Muffle furnaces; Rotary—J. R. C. August. E.P. 146,673, 8.5 and 17.6.19.

A HORIZONTAL, rotary muffle furnace is mounted concentrically within a rotary heating chamber, which is divided into flues by longitudinal, radial partitions, which also form a support for the muffle. The muffle is closed at one end, which abuts against the closed inner end of the combustion chamber. This end of the combustion chamber rotates in contact with a flat plate which forms one side of the flue leading from the furnace. The flat plate is provided with two openings which register with the ends of the longitudinal flues in the combustion chamber during its rotation. The flues are connected in such a way that the hot gases are forced to take a zig-zag course. A horizontal partition in the vertical flue leading from the furnace diverts the hot gas through one of the openings in the flat plate into the combustion chamber flues, whence it returns to the vertical flue through the other opening in the plate. A modification is described in which the muffle is heated by a gas or liquid-fuel burner arranged concentrically with the muffle at its rear end.—W. F. F.

Tunnel furnaces. A. Bigot. E.P. 147,391, 12.11.19. Conv., 6.9.19.

THE tunnel traversed by the goods to be heated is surrounded by hollow walls, the spaces in the walls being filled with chequerwork. The combustion of the (gaseous) fuel and air may take place either in the chequerwork, the goods being heated by radiation, or in the central goods tunnel, thus heating the goods directly, or partly in both. The gas for combustion is supplied underneath the hollow walls at the end where the goods emerge, and always passes through at least a portion of the chequerwork, passing (if desired) to the central tunnel through inclined ports. The air for com-

bustion after passing over the emerging goods in an extension of the furnace, thus cooling them, is free to pass either to the chequerwork in the hollow walls or to the central tunnel as determined by dampers in the outlet flues at the chimney end. As an alternative to, or in addition to passing the incoming air over the outgoing goods in the cooling extension, the walls of the extension may be hollow and the spaces filled with chequerwork, and air may be drawn through by suction and used for drying or other purposes.—B. M. V.

Tunnel-kiln. F. J. Leisen and E. S. Dunn. U.S.P. 1,345,605, 6.7.20. Appl., 31.1.19.

THE gases from a series of fire "zones," spaced apart along the length of the tunnel, are caused to pass through the kiln to the stack in the same direction as the materials under treatment.

—W. H. C.

Treating goods with fluids; Method of and apparatus for—H. R. Anders, Assr. to The Roessler and Hasslacher Chemical Co. U.S.P. 1,345,341, 6.7.20. Appl., 1.12.16.

THE materials are placed in separate compartments contained in a rotary vessel, and the treating liquid is circulated through the compartments in succession.—W. H. C.

Distillation-retort and separating tank. G. F. Rendall, Assr. to Carbon Products Co. U.S.P. 1,345,404, 6.7.20. Appl., 13.6.17. Renewed 26.5.20.

A RETORT is heated by gas burners which are supported on a perforated partition dividing the combustion chamber from a chamber for preheating the air supply for the burners.—B. M. V.

Grinding-mill. Crushing machine. W. G. Stevenson. U.S.P. (A) 1,345,714 and (B) 1,345,715, 6.7.20. Appl., 3.6. and 5.10.18.

(A) A pit is bridged by a framework which carries a pan rotating about a vertical axis. The framework also supports grinding rollers which are rotated about their own horizontal axes by the action of grinding, and have a slight vertical movement, but do not rotate about the axis of the mill.
(B) A table with several concentric troughs, each with its set of narrower rollers, is substituted for the pan and single set of grinding rollers. Scoops are provided to transfer the material under treatment from the innermost trough to the next outwards, and so on.—B. M. V.

Lifting and forcing apparatus for solids and semi-solids; Fluid or air direct-pressure—S. H. and C. H. Adams. U.S.P. 1,347,358, 20.7.20. Appl., 28.2.19.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Banded bituminous coal; Oxidation of the ingredients of —. Studies in the composition of coal. F. V. Tidswell and R. V. Wheeler. Chem. Soc. Trans., 1920, 117, 794—801.

SAMPLES of the four ingredients of the Hamstead Thick Coal (see J., 1919, 452 A, 614 A) have been subjected to the action of air or oxygen to determine their rates of oxidation and relative ignition temperatures. Determinations by a method previously described (J., 1919, 65 A) gave ignition temperatures ranging between 170° and 175° C. for vitrain, clarain, and durain. The rate of absorption of oxygen by each separate constituent was measured at different temperatures, the coal being subjected in each experiment to a preliminary exhaustion at 200° C. Of the three main ingredients of banded bituminous coal, the bright, vitrain and clarain, show greater liability to oxidise and to ignite than the dull durain. The difference between these ingredients is not, however, so great as to warrant any suggestion that the bright portions of Hamstead coal are primarily responsible for its liability to spontaneous combustion. The influence of fusain is uncertain. The authors consider it improbable that fusain has a preponderating influence in determining the actual ignition of the coal after self-heating has begun; but it is conceivable that the rapid absorption of oxygen by fusain at low temperatures may be attended by a sufficient evolution of heat to raise appreciably the temperature of the main mass of the coal, thereby causing the most inflammable ingredient (vitrain) to react more readily with oxygen—W. P.

Coal and the gases resulting from its distillation. L. Vignon. Ann. Chim., 1920, 13, 284—301.

ANILINE as a solvent furnishes a means of differentiating between different grades of coal. The "fat" coals contain a relatively high proportion of material soluble in aniline, whilst "lean" coals contain little soluble matter. The soluble portion of the coal is richer in hydrogen, poorer in ash, and gives a better coke than the insoluble portion. Boiling quinoline also exerts a considerable solvent action on "fat" coals. In the distillation of coal at successively increasing temperatures, the unsaturated hydrocarbons mostly pass over below 600° C., whilst methane and the saturated hydrocarbons are very abundant up to 800° C., their proportion then decreasing rapidly with rise in temperature. Hydrogen is only present in small amounts at 600° C., but is the predominating gas from 800° to 1000° C., diminishing somewhat from 1000° to 1200° C. Carbon monoxide is present in considerable amount above 1000° C. The more oxygen a coal contains, the more carbon monoxide and dioxide does it give on distillation, the relative proportions of these two gases depending on the conditions of distillation.—W. G.

Coal; Briquetting Oklahoma —. J. C. Davis. Chem. and Met. Eng., 1920, 23, 101—102.

SATISFACTORY briquettes were made from soft Oklahoma coal with the following average composition: Moisture, 2.04; ash, 10.93; vol. matter, 35.83; and carbon, 53.23%. The coal was ground to pass a 10-mesh sieve, mixed with an asphalt binder (penetration test 20, m.p. 71° C.) derived from crude petroleum oil, and compressed into briquettes under a pressure of 2000 lb. per sq. in. The finished briquettes had a heat value of 10,513 B.Th.U., this value being increased by about 20% by washing the coal. The best results were obtained when the temperature was maintained between 180° and 200° F. (82°—93° C.) and the moisture 3—5%. —C. A. M.

Coal; Transition from — to coke. E. Sinkinson. Chem. Soc. Trans., 1920, 117, 839—843.

COKE being a conductor of electricity, whilst coal is not, the transition from coal to coke can be followed by recording the change in conductivity which takes place when coal is heated. Preliminary tests with samples of coke briquetted with different proportions of pitch showed that more than 10% of free carbon had to be present in the non-conducting medium, pitch, to form an electrically conducting bridge. A series of cokes was prepared by carbonising samples of the same coal at temperature intervals of 100° up to 900° C. These were briquetted, those obtained from 700° to 900° with the addition of 10% of pitch. The resistance of the briquettes became too great to measure below a carbonising temperature of 500° C. The determinations showed that the critical temperature of the formation of coke lies between 500° and 550° C. This result was confirmed by experiments in which a continuous record of the conductivity was taken whilst the coal was being carbonised. Values obtained for cellulose were close to those obtained for coal, suggesting that the formation of free carbon at this temperature is due to the decomposition of the cellulosic constituents of the coal.—W. P.

Coal substitutes in gas manufacture. P. Schumann. J. Gasbeleucht., 1920, 63, 447—449.

GAS-COAL substitutes available in Bavaria gave the following results when carbonised in gas retorts:—

	% Coke.	Cub.m. gas.	Cal. val. of gas. K.-cal.	Sp. gr. of gas.	% CO, in gas.
Upper Bavarian coal	50	31.32	5,100	0.58	12.13
Lignite	24	30	3,400	0.60	14
Peat	15	30	3,400	0.75	22
Wood	15	30	4,000	0.70	25
Oil shale	60	30	3,800	0.90	32

All were defective in some respects, such as high content of ash or moisture, and high content of oxygen which led to the production of low-grade gas. The large proportion of carbon dioxide and moisture in the gas caused the removal of carbon deposits from the retort material and consequent loss by leakage. Purification was difficult and costly, especially when the sulphur content was excessive. No material yielded a satisfactory coke. The relative costs of production of 1 cub. metre of gas were as follows (the figures in parentheses are costs per unit of heat): From gas coal 1 (1), Upper Bavarian coal 1.201 (1.1), oil shale 1.709 (2.44), wood 3.018 (4.312), peat 2.111 (3.267), lignite 2.432 (2.34).—H. J. H.

Tar; Determination of — in gas. C. H. Stone and N. F. Prince. Gas Age. Gas. J., 1920, 151, 238.

THE gas is led into a wide glass tube which fits into a Gooch crucible containing a thick layer of

asbestos, the connexion being made by means of a rubber band. The bottom of the crucible is fitted into a rubber connexion on a glass tube, the base of which is constricted to pass through a hole in the stopper of an Erlenmeyer flask, whilst a second tube from the flask is connected with the gas meter. Purified dried gas is passed through the crucible for 1½ hrs., and the crucible then left for a few mins. in the desiccator before weighing. It is then again connected with the apparatus, and the gas under examination passed through it at about 2 to 6 cub. ft. per hr. for a period depending on the proportion of tar. Finally the dried purified gas is again conducted through the apparatus for 2 hrs. to remove the moisture, and the crucible containing the tar weighed as before.—C. A. M.

Ignition of gases. Part I. Ignition by the impulsive electrical discharge. Mixtures of methane and air. R. V. Wheeler. Chem. Soc. Trans., 1920, 117, 903—917.

THE relative "ignitibilities" of a series of mixtures of methane and air have been compared by the determination of the "minimum igniting currents" necessary to inflame the mixtures. These are the currents in the primary circuit of an induction coil, which, when broken at a constant rate, induced secondary discharges, at a fixed spark gap, just capable of igniting the mixtures. The gap in these experiments being formed by sharply pointed electrodes, the sparking voltage for a gap of constant width follows, over a wide range, a straight line relationship with the primary current. The steel contacts of the primary circuit breaker must be kept polished, and the sparking points clean, since any oxidation of the former or a speck of dust on the latter result in irregular values being obtained. The neglect of such precautions is the most probable cause of the "stepped" curves obtained by Thornton (Proc. Roy. Soc., 1914, A, 91, 17) and by Paterson and Campbell (Proc. Phys. Soc., 1919, 31, 193). A similar curve to the one obtained by plotting minimum igniting currents with a fixed spark gap against percentage of methane was obtained by plotting minimum spark gaps with constant current through the primary against percentage composition. The characteristics of these curves are the greatly increased difficulty of ignition as the limits of inflammability are approached, particularly on the high limit side; and the position of a range for optimum ease of ignition between 8.2 and 8.5% CH₄. It is suggested that the curve for relative igniting currents is compounded of the relative ignition-temperature curve and the inverse of the curve relating composition of the mixtures with initial speed of propagation of flame therein.—W. Coke; Apparatus for producing—. A. M. Smith. U.S.P. 1,346,515, 13.7.20.

THE coking chamber is provided with an extension which forms a quenching chamber, and is provided with an air-tight door at its lower end. A portion of a previously coked mass is severed and held as a plug at the end of the coking chamber, against which plug the new charge of coal to be coked may

rest. The previously coked mass is passed into the quenching chamber, and is separated from the plug by an air space until the mass in the quenching chamber is sufficiently cool.—A. G.

Furnace retorts [for partial carbonisation of coal]. C. H. Smith. E.P. 132,487, 16.4.19. Conv., 9.9.18.

THE retort is provided with a paddle-shaft, journalled in bearings which permit of limited universal movement, e.g., ball and socket members. The bearing has a spherical portion which is forced against a seat by springs or the like. The tubular shell of the retort is made of calorised steel (steel) with a coating of aluminium and is fitted with intermediate metal reinforcing bands contacting with partitions or walls which, with the above bands, define the circumferential heating flues for the retort. The end plates of the retort are formed of steel lined with masonry having a facing of cast iron and are connected with the tubular shell and adapted to support the universal bearings for the paddle-shaft. The end plates are relieved from excessive stress by means of counterweight devices.—A. G.

[Gas] retort mechanism. C. H. Smith. E.P. 147,965, 17.2.19.

A HORIZONTAL retort for coal distillation, of the kind in which a part of rotary conveyors operate in the two parts of a retort of heart-shaped cross-section, is provided with change-speed gearing between the conveyor shafts and the constant-speed motor which drives them. The conveyor shaft is journalled in bearings which are supported on a separate platform so that the shaft is not affected by movements of the end walls of the retort due to expansion or contraction. The end walls are formed so as to provide a recess for the bearing members.—W. F. F.

Gds producers. A. Ritte, and Soc. Franc. de Matériel Agricole et Ind. E.P. 145,807, 21.3.17.

THE producer is provided with several series of supplementary air inlets at different levels above the grate, which is divided into a number of sections, each of which can be agitated from the outside. Several gas outlets from the ash-pit are also provided to ensure an equal draught all over the grate, and a number of feed hoppers at the top of the shaft.—A. G.

Gas producers. H. H. Spicer. From J. F. Wells. E.P. 145,873, 1.4.19.

THE producer is furnished with an inclined grate disposed to support a body of fuel contained in a hopper, the fuel acting as a seal to the chamber. The hopper is flush with one side of the gas chamber and is provided with a movable gate for controlling the supply of fuel to the grate. The producer is intended specially for poor fuels, e.g., "cotton sticks," leaves, chopped straw, etc.—A. G.

Water-gas; Process and apparatus for producing enriched — and products and by-products of such process. J. W. Gibson and R. L. Wyman. E.P. 145,947, 30.5.19.

TAR is atomised and vaporised by admitting it to a current of steam and the current of the resulting mixture then meets the current of water-gas to be enriched. The tar residues are deposited as a by-product. The tar may be vaporised inside or outside the carburation apparatus, and it is exposed to a relatively large surface such as is provided by wooden grids.—A. G.

Coal gas and the like; Apparatus for washing and scrubbing —. F. G. Brockway. E.P. 145,856, 31.3.19.

SUPERPOSED tiers of troughs each have a downwardly directed inlet passage down the middle of

which liquid is caused to descend in the form of a curtain dividing the flow of gas. The two streams of gas pass down on either side of the curtain, and a certain volume is carried down into the main body of the liquid in the trough and is compelled to bubble up through the liquid, whilst the remainder is exposed to the action of the washing liquor running down over sloping plates composed of ribbed or corrugated metal. The gas leaves the troughs through outlet chambers filled with metal or other suitable scrubbing material on to which liquor is sprayed by jets.—A. G.

Ammonium chloride; Method of and apparatus for recovering — [from coal gas]. M. E. Mueller. U.S.P. 1,346,967, 20.7.20. Appl., 21.7.19.

THE gas, before it is cooled and separated from tar, passes along a main through which a quantity of aqueous and tarry liquor from the coolers and tar-extractors is circulated. The temperature in the main is kept above that at which much water vapour condenses from the gas, and quantities of the liquor are withdrawn from time to time, and are replaced by fresh liquor.—L. A. C.

Bituminous binders and processes for making the same. G. A. Henderson. E.P. 148,003, 30.4.19.

FROM 10 to 15% of water is added to natural or artificial bitumen or pitch preheated to above 212° F. (100° C.), and a mixture of petroleum (10% by vol.) and sulphur (10% by weight, of the pitch), previously heated together to about 400° F. (205° C.), is added. Chlorine is introduced into the mass until 3% by weight has been absorbed, and the mass is simultaneously heated and agitated under suction until the water and petroleum have been removed. Alternatively, vegetable matter, such as "denatured" hard wood chips, or mineral matter, such as particles of stone, slag, or the like, containing 10–15% of water, may be added instead of the water alone, or sulphur chloride may be used instead of sulphur and chlorine.—L. A. C.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Tar-still operation in hardwood distillation plants. L. F. Hawley and N. H. Calderwood, jun. J. Ind. Eng. Chem., 1920, 12, 684–685.

IN recovering the acetic acid remaining in the tar after distillation of the pyroligneous acid, the distillation with steam should be effected at as low a speed as possible, so as to increase the concentration of the distillate. More acetic acid can be obtained with less steam when the tar is kept at a higher temperature, i.e., when a higher pressure is maintained in the closed coils. Live steam is subsequently introduced, while the steam in the closed coils still remains at 50 lb. or higher, until 91 c.c. of distillate is required to neutralise 10 c.c. of $N/2$ alkali. The flow of live steam is then reduced to at least one-half its original speed (e.g., 30–35 galls. per hr.), and the distillation continued until not more than 9.4 c.c. of distillate is required to neutralise the alkali.—C. A. M.

Potash from kelp. Spencer. See VII.

PATENTS.

Hydrocarbons from coal or other carbonaceous matter; Process of and apparatus for extracting —. W. D. Roek. E.P. 145,906, 16.4.19.

PULVERISED coal is blown into the distillation chamber against the under side of a dome arranged near the top and having a diameter slightly less than that of the chamber. Superheated steam, with or without heated air, is blown in near the bottom of the chamber, and passes upwards so that the falling coal dust is subjected to the action of successive zones of increasing temperature. The residue falls into water at the bottom of the tower, from which it is periodically discharged, and the distilled hydrocarbons are drawn off through pipes at the top.—W. F. F.

Solid fuels; Destructive distillation of —. W. Beswick and N. E. Rambush. E.P. 147,311, 1.5.19.

CRUDE producer gas made in an ordinary by-product producer of the Mond type is introduced, without substantial cooling, into an internally heated gas retort. The gas as it leaves the producer contains the proportion of steam to producer gas which gives the best yields of valuable products, and especially ammonia, in the distillation of ordinary fuel in an internally heated retort.

—C. A. M.

Coal, shale, and so forth; Recovery of valuable products from the gases evolved in the destructive distillation of —. The Skinningrove Iron Co., Ltd., and E. Bury. E.P. 147,360, 16.8.19.

SULPHURIC acid is used for absorbing olefines from the gases produced in the destructive distillation of coal, etc., the heat for the absorbing plant being derived from the waste heat of the gases. These may first be freed from ammonia, benzene, etc., and then re-heated by means of the hot gases issuing from the carbonising plant. The sulphur is recovered by the use of hydrogen sulphide purifiers in combination with an apparatus for supplying sulphur dioxide derived from the plant in which alcohol is distilled from ethylsulphuric acid, and from the sulphuric acid concentration and heating plant, and this sulphur is used in the manufacture of sulphuric acid for the olefine scrubbers etc. The several processes are carried out in a closed cycle. (Cf. J., 1920, 94 A.)—C. A. M.

Filaments for electric lamps and the like; Methods of and apparatus for forming —. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 147,955, 9.5.17.

III.—TAR AND TAR PRODUCTS.

Phenolsulphonic acids; Rapid method for the analysis of —. L. Desvergues. Ann. Chim. Analyt., 1920, 2, 211–214.

FROM 5 to 6 g. of the sample is dissolved in water to 200 c.c., care being taken that the mixture does not become heated. *Total sulphuric acid (T)*. Ten c.c. of the solution is mixed with 25 c.c. of water and 25 c.c. of hydrochloric acid saturated with bromine, boiled for 15 mins., diluted with 200 c.c. of water, cooled, filtered, and the sulphuric acid in the filtrate determined as barium sulphate. *Combined sulphuric acid*. Ten c.c. of the solution is titrated with $N/2$ sodium hydroxide solution, using methyl-orange as indicator; this gives the free sulphuric acid plus one-half the combined sulphuric acid, or S , hence the combined sulphuric acid = $2(T-S)$. *Phenol*. Ten c.c. of the solution is

heated at 50° C. in a closed vessel for 30 mins. with 100 c.c. of water, 50 c.c. of hydrochloric acid (sp. gr. 1.18), and 25 c.c. of standardised potassium bromate-bromide solution; the mixture is then cooled and the excess of bromine determined iodometrically. The amount of free sulphuric acid present is calculated from the results obtained, and the proportion of phenol to combined sulphuric acid gives the quantities of mono- and disulphonic acids.

—W. P. S.

Aniline and ethyl alcohol; Catalysts which promote reaction between —. T. B. Johnson, A. J. Hill, and J. J. Donleavy. *J. Ind. Eng. Chem.*, 1920, 12, 636—644.

THE highest yields of diethylaniline were obtained by heating 100 g. of aniline hydrochloride with 360 g. of alcohol, 10 g. of sodium bromide, 5 g. of cupric chloride, and 10 g. of calcium chloride for 8 hrs. in an autoclave at 175°—180° C. The use of 95% alcohol instead of anhydrous alcohol reduced the yield of diethylaniline by about 7%. In the best results thus obtained the product contained only 5% of monoethylaniline. Zinc chloride is less efficient as a catalyst than calcium chloride, whilst potassium iodide is slightly more effective than sodium bromide. (*Cf. J.C.S.*, Sept.)—C. A. M.

PATENTS.

Sulphonating processes and apparatus for carrying out the same. F. C. Sutton. *E.P.* 147,967, 20.2.19.

AN aromatic hydrocarbon and sulphuric acid are charged through atomisers arranged opposite one another at the upper end of a tower. The tower is fitted with a condenser on top which returns any condensed hydrocarbon to the charging apparatus for the same, and the reaction product flows down baffle plates to the bottom of the tower, whence it is removed.—L. A. C.

Halogenated homologues of benzene; Production of —. L. P. Kyrides, Assr. to General Chemical Co. *U.S.P.* 1,345,373, 6.7.20. *Appl.*, 26.7.17.

TOLUENE is treated with chlorine in the presence of sulphur chloride.—A. J. H.

IV.—COLOURING MATTERS AND DYES.

Indigoid dyestuff; New —, 5-(dioxy-2,4-pyrimidine)-2-indoleindigo. J. Martinet and O. Dornier. *Comptes rend.*, 1920, 171, 184—187.

WHEN the technical melt of indoxyl is added to an acetic acid solution of alloxan heated on a water bath, 5-(dioxy-2,4-pyrimidine)-2-indoleindigo is obtained. It crystallises in opaque violet needles and dyes wool and silk heliotrope. Its sulphonic derivative dyes wool and silk violet. It sublimes above 300° C., giving violet-red needles. (*Cf. J.C.S.*, Sept.)—W. G.

Diazo compounds; Volumetric determination of — by reduction. E. Knecht and L. Thompson. *J. Soc. Dyers and Col.*, 1920, 36, 215—219.

BENZENEDIAZONIUM chloride may be titrated with titanium trichloride solution, using H acid as external indicator:

The titration must be made in dilute hydrochloric acid solution, since the reaction does not take place in the presence of moderately concentrated hydrochloric acid. The determination may also be made by adding an excess of titanium trichloride solution and titrating the excess with standardised Acid Green solution in the presence of sodium tartrate. Sodium hydrosulphite solution reduces benzenediazonium chloride, in hydrochloric acid solution,

quantitatively to phenylhydrazine hydrochloride; in this case the reduction is effected at 0° C. with an excess of the reagent and the excess then titrated with Acid Green solution. In cold alkaline solution *p*-nitro-sodiazobenzene is reduced directly to *p*-nitrophenylhydrazine by sodium hydrosulphite solution. Rosinduline or Safranin is used as internal indicator; the latter is not reduced until the reduction of the diazo group is complete but is reduced before the nitro group is attacked. In slightly alkaline solution containing sodium tartrate, *p*-nitro-sodiazobenzene is reduced by an excess of titanium trichloride to *p*-phenylenediamine and ammonia; the excess of the reducing agent may be titrated with Crystal Scarlet solution which acts as its own indicator.—W. P. S.

Henna (Lawsonia inermis). Chemical constitution of lawson. II. G. Tommasi. *Gaz. Chim. Ital.*, 1920, 50, I., 263—272.

LAWSONE, $\text{C}_{10}\text{H}_8\text{O}_3$, the colouring matter contained in henna leaves, is fixed well by wool and silk and rapidly and tenaciously by the skin. This compound is shown to be a hydroxynaphthoquinone, and is probably identical with 2-hydroxy-1,4-naphthoquinone. Its reactions with various reagents and its chemical transformations are described. (*Cf. J.C.S.*, Sept.)—T. H. P.

Sulphur colour and process of manufacturing the same from (A) aloe resin and (B) aloes. A. T. Appelbaum, Assr. to The Import and By-Products Co. *U.S.P.* (A) 1,346,153 and (B) 1,346,154, 13.7.20. *Appl.*, 10.6.18 and 5.2.19.

(A) ALOE resin is heated with sulphur and a solution of sodium sulphide. (B) Aloes, sulphur, and caustic soda liquor are heated under pressure, the product dissolved in water, and the dye subsequently precipitated.—A. J. H.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Adsorption capacity of —. *Electrometric micro-analysis of chlorine*. P. Rona and L. Michaelis. *Biochem. Zeits.*, 1920, 103, 19—30.

CELLULOSE does not appreciably adsorb surface-active non-electrolytes (heptyl alcohol, secondary octyl alcohol). Only in the case of extremely surface-active substances (*n*-octyl alcohol) can very slight adsorption be established. The more marked adsorption of electrolytes (dyes) by cellulose is due to the mineral content of the cellulose, principally calcium silicate, which is present in small quantities, sufficient to account for the adsorption observed, even in so-called ash-free filter paper. The estimation of chlorine by the electrometric method with a calomel electrode is described and discussed.—S. S. Z.

Sulphite cellulose waste liquor; Utilisation of —. R. H. McKee. *Pulp and Paper Mag.*, 1920, 18, 715—718.

A NEW method is described in which the waste sulphite liquor is freed from most of its sulphur dioxide by the action of a counter-current of steam in a desulphurising column, 16 ft. high, and is then evaporated to about half its vol. in an evaporator of the thermo-compressor type. It is then cooled to about 29° C. by means of a counter current of water, and pitched with yeast, together with hydrolysed

yeast, ammonium sulphate, and calcium acid phosphate, while a slow current of air is introduced into the bottom of the fermentation tank. After 60–72 hrs. the alcohol is distilled, preferably in a continuous still, and redistilled in an intermittent still on to the upper plates of which is run a dilute solution of soda ash to neutralise the free sulphur dioxide. The yield of 95% alcohol varies from 0.55 to 1.35% of the vol. of waste liquor; av. 1.0%, at a total cost of 28.4 cents per U.S. gall. The residual sulphite liquor from the stills yields a dry residue suitable for fuel. A typical liquor yielded a residue with heat value of 7950 B.Th.U. per lb., ash 13.9; sulphur in residue 5.4; and sulphur in ash, 1.9%. Each ton of pulp yields about 2772 lb. of a mobile pitch containing 50% of solids.—C. A. M.

PATENTS.

Mergerisation [of cotton-viscose silk unions]. S. M. Jones, Assr. to Arnold Print Works. U.S.P. (A) 1,346,802 and (B) 1,346,803, 13.7.20. Appl., 12.5.20.

COTTON fabrics containing viscose silk are mergerised without damage when (A) glycerin or (B) monoacetin is added to the caustic soda solution. (Cf. U.S.P. 1,343,138–9; J., 1920, 542 A.)—A. J. H.

Yarn in hank form; Machine for treating —. J. S. and S. S. Lord. U.S.P. 1,346,833, 20.7.20. Appl., 15.12.19.

SEE E.P. 136,666 of 1918; J., 1920, 186 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Phosphoric acid; Production of — by smelting phosphate rock in a fuel-fed furnace. W. H. Waggaman and T. B. Turley. J. Ind. Eng. Chem., 1920, 12, 646–650.

MIXTURES of calcium phosphate, quartz flour, and carbon yield nearly the whole of the phosphorus as P_2O_5 , when heated in an open or closed crucible in an oil-furnace, provided that the temperature is kept at about 1500° C., and that reducing conditions are maintained until a fusible slag has been formed. The addition of a small amount of alumina is advantageous, since it lowers the m.p. of both acid and basic slags. The proportion of silica required varies with the composition of the phosphate rock. In experiments on a large scale the material was used in the form of small briquettes prepared from a mixture of 20 pts. of finely-ground natural phosphate (containing 20–25% clay-like constituents), 16.6–22 pts. of silica, and 4.8–5.6 pts. of coke, with 10% water. The flames and gases of the furnace were made to pass through a central shaft, and so brought into direct contact with the material. Copious fumes containing up to 93.55% of the P_2O_5 were liberated, whilst the residual briquettes contained from 1.63 to 11.52% P_2O_5 , according to their degree of fusion.—C. A. M.

Potash from kelp. II. Distillation of kelp at low temperatures. G. C. Spencer. J. Ind. Eng. Chem., 1920, 12, 682–684.

THE distillation of dried kelp in an oil-jacketed wood-distillation retort at temperatures not exceeding 320° C., yielded a residual charcoal which had not been sufficiently heated either to form a suitable filtering medium or for the extraction of potash. Hence kelp should be distilled at a much higher temperature.—C. A. M.

Ammonia; Iodic acid as a characteristic micro-chemical reagent for gaseous —. G. Denigès. Comptes rend., 1920, 171, 177–179.

WHEN a drop of a 10% solution of iodic acid is exposed to an atmosphere containing ammonia it becomes covered with a crystalline film of ammonium iodate. These crystals may readily be identified under a microscope, and the reaction is not given by volatile amines under these conditions. For the detection of traces of ammonium salts in a solution, the latter is first evaporated to a small bulk and then the ammonia is liberated by the action of magnesia and detected as above.—W. G.

Evaporation [of solutions of salts]; Spontaneous —. H. B. Weiser and E. E. Porter. J. Phys. Chem., 1920, 24, 333–341.

SOLUTIONS of copper sulphate, potassium ferrocyanide, and potassium tartrate all evaporate more slowly than pure water. The rate of evaporation furnishes an approximate method of estimating the lowering of the vapour pressure of solutions. Chromic anhydride in aqueous solution exists mainly as dichromic acid.—J. F. S.

Zinc oxide, phosphorus pentoxide, and water; The system — at 25° C. and 37° C. N. E. Eberly, C. V. Gross, and W. S. Crowell. J. Amer. Chem. Soc., 1920, 42, 1433–1439.

THE tetrahydrate of normal zinc phosphate, $Zn_3(PO_4)_2 \cdot 4H_2O$, is prepared by saturating a solu-

tion of phosphoric acid (50% P_2O_5) with zinc oxide at the boiling point, cooling in ice-cold water and stirring violently while 10 vols. of ice-cold water are added, filtering and warming in a water bath, when shining orthorhombic plates of the tetrahydrate separate. At $25^\circ C$. the compounds $Zn_3(PO_4)_2 \cdot 4H_2O$, $ZnHPO_4 \cdot 3H_2O$, and $Zn(H_2PO_4)_2 \cdot 2H_2O$ separate from the system zinc oxide, phosphorus pentoxide, and water, whilst at $37^\circ C$. the additional compound $ZnHPO_4 \cdot H_2O$ is obtained.—J. F. S.

Manganese salts; Simplification of Caron and Raquet's reaction for —. G. Denigès. *Ann. Chim. Analyt.*, 1920, 2, 215–216. (*Cf. J.*, 1919, 574 A, 662 A.)

FIVE c.c. of the manganese salt solution is treated with a few drops of sodium hydroxide solution and shaken until a brown coloration is obtained; saturated oxalic acid solution is then added drop by drop. The brown coloration disappears and is replaced by the red coloration characteristic of manganese salts.—W. P. S.

Zirconium; Investigations on —. J. W. Marden and M. N. Rich. *J. Ind. Eng. Chem.*, 1920, 12, 651–656.

Preparation of zirconium oxide:—Good yields were obtained from zircite by fusion with sodium carbonate and hydroxide, lixiviation with hot water, digestion of the residue with hydrochloric acid (1:1), neutralisation of the filtrate with sodium carbonate, and precipitation of the zirconia by means of sulphur dioxide: by fusion with nitre cake, extraction with hot water, and precipitation as zirconium phosphate; and by decomposition with sulphuric acid, extraction with cold water, neutralisation of the filtrate with sodium carbonate, and ignition of the precipitated basic zirconium sulphate: this yields 99.8% ZrO_2 . *Pure potassium zirconium fluoride* is prepared by dissolving zirconium oxide in hydrofluoric acid, treating the solution with potassium carbonate in sufficient quantity to form K_2ZrF_6 , and recrystallising the salt three times. When fused in a graphite vessel at $900^\circ C$. and treated with $1\frac{1}{2}$ times its weight of aluminium it yields an alloy, which when freed from excess of aluminium by treatment with sodium hydroxide solution, and then with hydrochloric acid (1:1), consists of silvery-white crystals containing 30% Al and 68% Zr, with about 1% Fe, Si, Ti, etc. This aluminide (Zr_3Al_4) may be prepared in impure condition by fusing zircite with sodium fluoride and then adding aluminium. *Metallic zirconium* was prepared in its various forms, the physical and chemical properties of which are described. Coherent metal obtained by aluminothermic reduction contained: Zr, 99.40–99.50; Ti, 0.45–0.40; Fe, 0.01–0.02; and Al and Si (diff.) 0.14–0.08%. (*See J.*, 1910, 218, 358; 1913, 197.) Methods for determining zirconium and separating it from other metals are also discussed. (*Cf. J.C.S.*, Sept.)—C. A. M.

Mercuric oxycyanide. A. J. Jones. *Pharm. J.*, 1920, 105, 87–89.

THE composition of commercial mercuric oxycyanide is very variable and the pure salt is never supplied. The pure salt is stated to be dangerous to handle, and explosions have occurred during its manufacture. It was prepared by grinding 40 g. of mercuric cyanide and 30 g. of yellow mercuric oxide with 15 c.c. of water and, after 15 mins., adding 0.5 c.c. of 20% sodium hydroxide solution. Next day the mass was diluted with 200 c.c. of water, acidified slightly with acetic acid and added to 700 c.c. of boiling water containing 20 g. of mercuric cyanide. The solution was filtered, the filtrate

cooled, the separated crystals collected, washed with a small quantity of cold water and dried over sulphuric acid.—W. P. S.

Hydrogen peroxide; Preservation of —. H. R. Jensen. *Pharm. J.*, 1920, 105, 87.

HYDROGEN peroxide may be preserved by the addition of acetanilide (0.002%) and hydrochloric acid (2%) or phosphoric acid (0.1%); boric acid and amino compounds in general also act as preservatives.—W. P. S.

Finely divided gases; Action of extremely —. [*Reduction of carbon dioxide by hydrogen.*] C. Zenghelis. *Comptes rend.*, 1920, 171, 167–170.

THE reduction of carbon dioxide in aqueous solution by very finely divided hydrogen (*J.*, 1920, 363 A) steadily diminishes in velocity with the time. It takes place very slowly in the dark, but is markedly accelerated by sunlight and still more so by ultraviolet rays. In all cases the formaldehyde first produced undergoes polymerisation.—W. G.

Acetic acid; Distribution of — between water and charcoal. A. Pickles. *Chem. News*, 1920, 121, 49.

WOOD charcoal removes acetic acid from its solutions, rapidly at first, but several hours are required for equilibrium to be reached. The concentration of the acid in the charcoal varies with the nature and condition of the charcoal. Animal charcoal, which removes the acid almost entirely by adsorption, was the most efficient agent, and fruit-stone dust charcoal the best of the vegetable charcoals tried. (*Cf. J.C.S.*, Sept.)—C. A. M.

Charcoal; Adsorption by —. I. Relation of service time to adsorption and absorption. II. Relation of oxygen to charcoal. H. H. Lowry and G. A. Hulett. *J. Amer. Chem. Soc.*, 1920, 42, 1393–1419.

THERE is no relationship between the length of time charcoal has been in use and the adsorption of gases such as nitrogen and carbon dioxide. The adsorptive power of charcoal is changed as much as 100% by changes in the mode of preparation. Water is not adsorbed by charcoal, but absorbed, that is it is held by capillary action. The diameter of the capillaries of charcoal varies from 2.8×10^{-7} cm. to 9.2×10^{-7} cm., and the surface varies from 160 sq. m. to 436 sq. m. per g. The variation in surface is not always accompanied by a corresponding variation in adsorptive capacity. The adsorption of oxygen by charcoal is anomalous owing to a surface combination of the oxygen with the carbon at ordinary temperatures. The product is a solid stable oxide of carbon, which on heating breaks up into carbon monoxide and carbon dioxide and is to be regarded as an intermediate compound in the combustion of charcoal. (*See Armstrong, J.*, 1905, 473.)—J. F. S. *Calcium cyanamide waste product.* Baumann. *See IX.*

PATENTS.

(A, B) *Ammonia; Process of oxidising — to nitric acid.* (C) *Process of catalytically combining gases.* A. Henwood. U.S.P. (A) 1,347,158, (B) 1,347,159, and (C) 1,347,160, 20.7.20. Appl., (A) 8.7.18, (B and C) 9.1.19.

(A) A mixture of gases is caused to react by passage through a catalyst in the form of a diaphragm so thin that practically the whole of the material is active. (B) In the oxidation of ammonia to nitric acid the temperature is reduced by non-automatic

means, and if the minimum permissible temperature is approached heat is supplied automatically. (c) A mixture of gases is passed over a catalyst supported on a carrier provided with flexible supports, to allow for expansion and contraction under temperature variation.—L. A. C.

Ammonium sulphate; Production of —. C. W. Bailey, H. S. Denny, W. H. H. Norris, and H. E. F. Gould-Adams. E.P. 146,516, 5.1.18.

NITRE cake, sodium sulphate, ammonium sulphate, and water are brought together under such conditions that a quantity of anhydrous sodium sulphate is precipitated equivalent to the sodium present in the nitre cake, and, after removal of the precipitate, the liquor is used instead of sulphuric acid to absorb ammonia, e.g., from Mond gas, coke-oven gas, or the like. The proportions of nitre cake, sodium sulphate, and ammonium sulphate in the original mixture may either be so adjusted that after absorption of the ammonia and subsequent evaporation of a portion of the water, ammonium-sodium sulphate crystallises out, and after removal of the crystals and further evaporation of a portion of the remaining water, pure ammonium sulphate separates on cooling, or that after absorption of the ammonia and evaporation of a portion of the water pure ammonium sulphate crystallises out, in which case the liquor separated from the crystals is suitable for the treatment of a fresh supply of nitre cake.—L. A. C.

Ammonium salts; Purification of —. V. Bredlik. U.S.P. 1,346,106, 13.7.20. Appl., 23.8.19.

AMMONIUM salts containing free acid are neutralised with crude ammonia which has been freed from organic impurities.—L. A. C.

Alumina; Method of producing —. Norsk Hydro-Elektrisk Kvaestofaktieselskab. E.P. 134,531, 25.10.19. Conv., 26.10.18.

ALUMINA is precipitated in a granular form, which can be readily filtered and washed, by treating a solution such as that obtained by dissolving labradorite or the like in acids with ammonia above 100° C. and under a pressure of 10–15 atm. Ammonia is regenerated from the liquor after separation of the precipitated alumina by treatment with finely ground labradorite, under a pressure slightly higher than that in the precipitation vessel, and the ammonia gas generated can thus be passed directly into the precipitation vessel for treating a fresh supply of solution.—L. A. C.

Cuprous oxide; Process for the manufacture and use of —. E. C. R. Marks. From Hüttenwerk Niederschöneweide A.-G. vorm. J. F. Ginsberg. E.P. 147,958, 1.2.18.

CUPROUS oxide in a form especially suitable for the manufacture of copper compounds, such as copper sulphate, cuprammonium salts, etc., is prepared from copper which has been refined by blowing, to about 99% purity, by continuing the oxidation until the whole of the liquid copper has been converted into a thin liquid mass of cuprous oxide. When cold the product is ground to a fine powder.—L. A. C.

Hypochlorites; Electrolytic apparatus for the direct production of —. P. Pestalozza. E.P. 148,095, 19.12.19.

A SOLUTION of a metallic chloride is fed into one end of a vat divided into a number of cells by transverse partitions provided with openings so arranged that the liquor passes through the series in a zig-zag course. Each cell is provided with a vertical anode plate of platinum, two vertical cathode plates of carbon, graphite, or the like, and glass cooling

coils. The vat and electrode supports are formed by moulding under pressure a mixture of 80–85% of Portland cement and 20–15% of asbestos fibres, to which the requisite amount of water has been added; after drying, the vat is rendered non-porous and inert to chlorine by immersion for 1 hr. in a bath of paraffin and a neutral oil at 200° C.

—L. A. C.

Alkali-metal hydrates [hydroxides]; Process of producing —. H. W. Charlton, Assr. to American Potash Corp. U.S.P. 1,346,002, 6.7.20. Appl., 12.10.16.

MINERAL material containing an alkali metal is heated and digested with a mixture containing an alkali hydroxide and an alkaline-earth hydroxide under a pressure and for a time sufficient to produce the desired alkali hydroxide, which is then extracted from the mixture.—L. A. C.

Pyrophosphates; Process of producing —. H. A. Webster. U.S.P. 1,346,148, 13.7.20. Appl., 24.9.19.

MONOCALCIUM phosphate is allowed to react with a salt containing a stronger basic ion than the calcium ion and a weaker acid ion than that of pyrophosphoric acid.—A. J. H.

Asbestos; Process of bleaching —. C. L. Hill. U.S.P. 1,346,316, 13.7.20. Appl., 1.5.20.

Moist asbestos fibres are treated with an acid gas, and the material is then washed with water to remove soluble salts.—L. A. C.

Silicates; Apparatus for treating —. W. Glaeser, Assr. to Potash Extraction Corp. U.S.P. 1,347,024, 20.7.20. Appl., 19.9.17.

A STATIONARY furnace chamber is connected by means of a rotary tubular shell with a stationary stack chamber. A kiln mounted in the shell extends through the chambers and projects through the front wall of the furnace chamber into a receiver.—J. W. D.

Hydrogen; Process of and apparatus for producing —. L. S. Abbott, Assr. to The Improved Equipment Co. U.S.P. 1,345,905, 6.7.20. Appl., 6.11.15.

AN apparatus for the manufacture of hydrogen by the process in which there are separate heating, steaming, and reducing stages contains a number of units each of which is so constructed that the three stages can be performed therein; the number of units is adjusted according to the times of operation of the different stages, so that by simultaneous operation of the stages in different units a continuous supply of hydrogen is obtained.—L. A. C.

Cyanogen and ammonia; Method of producing —. R. L. Gould. From Balfour-Guthrie Investment Co. E.P. 145,824, 25.3.19.

VIII.—GLASS; CERAMICS.

Glass-pot mixtures; Porcelain —. D. H. Fuller. J. Amer. Ceram. Soc., 1920, 3, 569—570.

SEVEN glass-pot bodies of a porcellaneous character were made from felspar, ball clay, kaolin, and grog (white ware bisque) of various grades, and the water content in plastic state, shrinkage on drying, modulus of rupture in dry and fired states, contraction under a load of 50 lb. per sq. in. at 1350° C., and refractoriness determined. The water-content and drying shrinkage were similar in all the mixtures; the transverse strength in both dry and fired states was greatest with little 10–20-mesh grog and a larger proportion of 20–80-mesh grog. These bodies withstood load conditions at working temperatures satisfactorily. The most rapid rate of vitrification occurred when the bodies were fired between cones 11 and 13; coarser grog retarded vitrification and finer grog promoted it. The effect of the addition of felspar in promoting vitrification was greater the finer the grog, but more than 8% of felspar could not be used without impairing the rigidity of the pots at 1450° C. The most satisfactory body appears to be felspar 6·5, ball clay 22·0, kaolin 23·5, 10–20-mesh grog 16·8, 20–40-mesh grog 19·2, 40–80-mesh grog 9·6, and 80-mesh to dust grog 2·4%.—A. B. S.

Glass pots; Lining for —. S. R. Scholes. J. Amer. Ceram. Soc., 1920, 3, 498—500.

A NON-POROUS lining for glass pots is made by adding 5–10% of felspar to the mixture ordinarily used for the pots, lining the glass-pot to a thickness of about $\frac{1}{2}$ in. up to the metal line and to a gradually diminishing thickness for a further 8 in. with the felspathic mixture, and then firing in the usual manner. Owing to the density and porcellaneous structure of the lining, the attack of the glass is reduced to a minimum, the useful life of such lined pots when used for making potash-lead glass being two or three times that of ordinary pots.—A. B. S.

Glass to metal joints. E. C. McKelvy and C. S. Taylor. J. Amer. Chem. Soc., 1920, 42, 1364—1377.

SOLDERED joints between metal and glass tubes are best made by roughening 15–20 mm. of the glass tube, which must fit easily into the metal tube, and then coating it with platinum by covering it with a suspension of platinum chloride in lavender oil and burning off the volatile matter in a Bunsen flame. The inside of the metal tube is coated with tin, solder, or lead, heated to melt the coating, the platinised end of the glass tube then inserted, and the whole allowed to cool slowly. Fused joints between metal and glass are made by coating the inside of the metal tube with Kraus flux (equal weights of zinc oxide, borax, and powdered soda-glass fused together), the glass tube is flared out to a flat ring of a width equal to three times the thickness of the glass wall and whilst hot pressed into the flux-lined metal tube. Fusion is completed by heating the outside of the metal tube in such a way that the glass tube is kept cool enough to prevent deformation.—J. F. S.

Refractories; Possible explanation of failure under load at high temperatures as displayed by fire-clay —. A. S. Watts. J. Amer. Ceram. Soc., 1920, 3, 448—459.

FIRECLAY refractories may fail at 1300° C. when under a sufficient pressure even when the proportion of fluxes is extremely low and when the $\text{Al}_2\text{O}_3:\text{SiO}_2$ ratio resembles that of pure kaolinite. Refractory articles with a high content of ball clay do not show this weakening and as they do not develop sillimanite, it is suggested that the production of

sillimanite when fireclays are heated to 1300° C. is an important cause of weakening at that temperature.—A. B. S.

Firebricks; Behaviour of — in malleable furnace bungs. H. G. Schurecht. J. Amer. Ceram. Soc., 1920, 3, 556—559.

COMPLETE 7-ft. arches each containing 40 bung-bricks arranged as headers, were built in over the firebox of a 40-ton malleable iron furnace and heated repeatedly. Of six different kinds of bricks examined, three, made by the soft mud process, withstood 18 heatings; these contained over 40% Al_2O_3 and had porosity about 15%, bulk sp. gr. about 2·0, refractoriness corresponding to cone 32, deformation when heated at 1350° C. under a load of 25 lb. per sq. in. 6–15%. Two other bricks of similar composition, refractoriness, and porosity but only 1·9 bulk sp. gr. withstood 12 and 14 heatings respectively. A dry-press brick containing 29·8% Al_2O_3 , sp. gr. 2·03, porosity 13·4%, and deformation under the load-test 11·8%, only withstood three heatings.—A. B. S.

[Pottery] *sagger mixtures; A high temperature transverse-strength test as a method of testing* —. S. C. Linbarger and C. F. Geiger. J. Amer. Ceram. Soc., 1920, 3, 543—555.

TEST-PIECES, measuring $8 \times 2\frac{1}{2} \times 2$ in., of various mixtures to be used in the manufacture of saggars, fired to cone 12 in commercial sagger kilns, and ground so as to have two flat and parallel faces, were supported on two carbofrax prisms with a 6 in. span, heated to 1300° C. for 45 mins., and the transverse strength determined at that temperature. The load was transmitted from a weighted lever through a carbofrax cylinder resting on a carbofrax prism, the effective load on the test-piece being increased at the rate of 6 lb. per min. The modulus of rupture,

$M = \frac{3Pl}{2bd^2}$, in which P is the breaking load in lb., l the length of span in inches, and b and d the width and depth of the test-piece in inches. During the test the piece must be protected from direct contact with the flame. When cold some sagger mixtures had moduli as low as 450, others as high as 3000 lb. per sq. in. At 1300° C. the weakest mixture tested had a modulus of 70 lb. per sq. in. and the strongest 600 lb. per sq. in. The tests already made suggest that mixtures with a modulus of over 350 lb. per sq. in. at 1300° C. are suitable for saggars.—A. B. S.

Terra-cotta glazes and colours; Composition of kiln gases and their effect on —. F. B. Ortman. J. Amer. Ceram. Soc., 1920, 3, 476—488.

THERE is an appreciable amount of sulphur trioxide in the gases passing through kilns in which terra-cotta is burned, but in the early stages of heating it is rapidly removed by the excessive ventilation. The fused glaze is not readily susceptible to the action of sulphur trioxide on its surface. The danger of sulphuring is greatest between "red heat" and the fusion of the glaze, because the sulphur dioxide produced on heating from the pyrites in the clay encounters a moist atmosphere, and forms sulphuric acid, which may cause any or all of the following defects:—Sulphur dioxide may be displaced by silica from combined sulphuric acid during the fusion of the glaze and the escaping gas may form blisters. The sulphuric acid may displace boric acid in the glaze. The sulphuric acid may react with colouring oxides and other fluxes and prevent the development of the desired colour and texture. The occurrence of these defects may be lessened by providing the maximum ventilation consistent with satisfactory heating of the kiln; by firing so as to avoid choking the flues with large quantities of gas; by maintaining an adequate supply of secondary

air in the fire-boxes, and by maintaining an adequate draught and oxidising conditions throughout, particularly after the trial holes have been closed.

—A. B. S.

Fish-scaling [in enamelled ware]. J. B. Shaw. J. Amer. Ceram. Soc., 1920, 3, 489—497.

The defect known as "fish-scaling" on enamelled sheet steel consists of small pits formed by a speck of the ground-coat enamel "jumping off." The pits may be very small and numerous, or they may be $\frac{1}{8}$ — $\frac{1}{4}$ in. diam. and less numerous. The defect is commonest on heavy gauge steel but must be distinguished from blistering (which is due to impurities rolled into the steel) and from pitting due to rusting of the metal. In the author's opinion, fish-scaling is due to several causes, the chief of which are to be found in the preparation, application, and burning of the enamel and particularly in the use of enamels with too large a proportion of finely ground material.—A. B. S.

Enamels; Relative action of acids on —. W. J. Amer. Ceram. Soc., 1920, 3, 560—567.

In further work by the Sub-Committee on Enamels of the Standards Committee of the Amer. Ceram. Soc. (cf. Poste, J., 1919, 287 A), various enamelled vessels were filled with a solution containing 6 oz. of citric acid in 1 quart of water (=15.73%) and kept for 23 hrs. at 12°—20° C. The liquid was then transferred to a measuring flask, the vessel rinsed with water which was added to the liquid, and the whole diluted to 500 c.c. Two portions of 100 c.c. each were withdrawn, evaporated to dryness in weighed platinum dishes, and ignited. The gain in weight in each case, less the ash in the citric acid, indicates the amount of enamel removed by the acid. If a 0.3% solution of malachite-green is poured into the vessels which have been treated with acid, and after five minutes the solution is poured out and the dishes rinsed with water, the resulting discoloration of the etched portion appears to be approximately proportional to the activity of the acid used.—A. B. S.

PATENTS.

Glass-furnace. J. R. Seohy. U.S.P. 1,347,181, 20.7.20. Appl., 28.11.19.

A GLASS furnace is provided with floaters and adjacent pockets for collecting the scum held back by the floaters.—H. S. H.

Brick; Light-weight refractory —. R. C. Purdy and M. F. Beecher, Assrs. to Norton Co. U.S.P. 1,345,632, 6.7.20. Appl., 1.11.18.

Porous bricks are made from burned refractory lignite clay.—L. A. C.

Resistance material. H. T. Bellamy and B. T. Sweely, Assrs. to Western Electric Co. U.S.P. 1,346,874, 20.7.20. Appl., 16.11.18.

A compound having a high electrical resistance at high temperatures, comprises talc, silica sand, ball clay, and a glass binder.—H. S. H.

Refractory composition and process of making same. A. T. Hineley, Assr. to National Carbon Co. U.S.P. 1,346,959, 20.7.20. Appl., 9.10.19.

A REFRACTORY composition comprises fully shrunk, graded carbon particles in mutual contact, and a ceramic bonding material proportioned to fill the interstitial spaces.—H. S. H.

Glass; Process and apparatus for separating — into mould charges. W. J. Mellersh-Jackson. From Hartford-Fairmont Co. E.P. 146,617, 10.4.19.

IX.—BUILDING MATERIALS.

Calcium cyanamide; Preparation of Portland cement from a waste product from —. J. Baumann. Chem.-Zeit., 1920, 44, 562.

In the decomposition of calcium cyanamide into calcium carbonate and ammonia a waste sludge is left in the autoclave. When dried at 100° C. this is a black powder of variable composition. One sample contained: SiO₂, 3.55; SO₃, 0.98; Fe₂O₃, and Al₂O₃, 2.05; CaO, 43.85; MgO, trace; free carbon, 15.00; and loss on ignition, 34.67%. When mixed with the calculated proportion of dried clay and heated in a furnace to a white heat it yielded a cement with the properties and approximate composition of normal Portland cement.—C. A. M.

PATENTS.

Cement; Method of making —. F. L. Smidth & Co. E.P. 137,534, 8.1.20. Conv., 8.1.19.

MOLER, silicious earth, diatomite, or infusorial earth, previously burnt to about 900° C., is mixed and ground with Portland cement. The amount of moler which can be added advantageously is doubled by burning, while a mixture containing 25% by weight of burnt moler (referred to the cement) has a strength more than 50% greater than a mixture composed of the same proportions of raw, dried moler and cement.—H. S. H.

Wood; Fireproofing of —. H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,346,287, 13.7.20. Appl., 17.8.18.

WOOD impregnated with a solution of barium sulphide is treated with gaseous carbon dioxide, whereby hydrogen sulphide is expelled and barium carbonate is formed within the body of the wood.—L. A. C.

Cement, cement-concrete, reinforced concrete, lime trass mortar, natural stone or bricks, and the like; Process for forming a covering and hardening coating on, or impregnating articles or plastering of —. L. A. and A. J. Sanders. E.P. 145,806, 26.4.16. Addn. to 102,042.

ARTICLES or plastering made according to the original patent (J., 1919, 863 A) are heated, wholly or locally.

Woods; Composition for hardening and preserving impregnable soft —. A. Lambert. U.S.P. 1,346,830, 20.7.20. Appl., 4.1.19.

SEE E.P. 139,974 of 1919; J., 1920, 336 A.

Bricks, tiles, clinker, and the like; [Plant for] manufacture of —. Burners for firing brick kilns, furnaces, or the like. H. Atkins and J. A. Colquhoun. E.P. 147,239 and 147,240, 16.11.18.

Bituminous binders. E.P. 148,003. See IIA.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Electrolytic iron; Annealing of —. J. Cournot. Comptes rend., 1920, 171, 170—171.

HEATING at 950° C. for 2 hrs. or at 1050° C. for 1 hr. is necessary to obtain complete annealing of electrolytic iron. At 850° C. annealing is not complete even after 4 hrs. The characteristic structure due to the presence of the hydride is present after annealing at 650° or 750° C., but it has disappeared after annealing at 850° C. for 1 hr., although the hardness has not reached its minimum.—W. G.

[Steel;] *Flaky fracture and segregation phenomena* [in —]. P. Oberhoffer. *Stahl u. Eisen*, 1920, 40, 705—713, 872—878.

MICROGRAPHIC examination after etching with an ammoniacal copper reagent showed that the so-called flaky fracture of steel (*cf.* J., 1919, 289 A, 368 A, 683 A, 733 A) is closely connected with phosphorus-segregation resulting from the formation of blow-holes in the interior of the metal.

Steels; Dynamic tests on special —. A. Gessner. *Stahl u. Eisen*, 1920, 40, 781—783.

DYNAMIC tensile tests on an Amsler machine and static tests were carried out with two qualities of nickel-chrome steel and on ordinary carbon steel after they had undergone various heat treatments. With the special steels, which were of marked tenacity and had a breaking stress of about 100 kg. per sq. mm., the ability to flow under stress was developed completely in the short period of 0.003—0.005 sec. in the dynamic tests, and higher values for the ultimate tensile strength and the work utilised in producing deformation at fracture were obtained than in the corresponding static tests. The reduction of area was also greater.—J. W. D.

High-chromium steel; Heat treatment of —. H. J. French and Y. Yamauchi. *Chem. and Met. Eng.*, 1920, 23, 13—16.

SAMPLES of chromium steel containing 12.4—13.2% Cr and 0.27—0.29% C were quenched in oil from various temperatures. With increasing quenching temperature both the Brinell and Shore hardness increase until 1066° C. (1950° F.) is reached. Maximum hardness is generally obtained by quenching from or above this temperature, although in some cases with higher temperatures the hardness decreases owing to retention of solid solution. The best combination of strength and ductility is obtained by quenching from 955° C. (1750° F.), which condition coincides with maximum tensile strength. Ductility as measured both by elongation and reduction of area decreases rapidly as the quenching temperature increases. It attains a very low value at 1010° C. (1850° F.), above which temperature it remains practically constant. Maximum ductility does not correspond with maximum tensile strength or proportional limit. Tempering previously quenched samples for short periods at temperatures up to 427° C. (800° F.) decreases brittleness. Tempering above 427° C. causes marked decrease in strength and hardness. Ductility increases to a greater extent in tempered samples quenched from 955° C. The most rapid change in tensile properties and hardness occurs in tempering between 427° and 538° C. (800°—1000° F.). The structure of samples tempered for short periods tends to persist even when tempering is effected at temperatures comparatively close to the lower critical range.

—J. W. D.

Corrosion of iron and steel. W. D. Richardson. *Amer. Inst. Chem. Eng.*, June, 1920. [Advance copy.] 94 pages.

WITH ordinary varieties of iron and steel oxygen determines the beginning of corrosion, and the rôle of oxygen appears to be that of a depolariser, since it combines not only with hydrogen at the corrosion cathodes, but also with ferrous iron at the corrosion anodes. Corrosion will start in the absence of oxygen, but it soon drops to a negligible rate. Corrosion produced by salt solutions depends principally on the amount of oxygen in solution. Oxygen causes much more rapid corrosion than air, but may also produce a protective layer of rust not produced in air, thus reducing corrosion below that in air under similar conditions. Rust accelerates corrosion by acting as a cathode, but may also reduce corrosion by adhering and acting as a pro-

tector. This is more noticeable with cast iron than with the purer forms of iron. Carbon dioxide only plays a minor rôle in the corrosion of iron. Experiments carried out on the corrosion of 12 common varieties of iron and steel under 8 different conditions (in still and agitated water and brine) for 1000 days indicated that pure iron corrodes relatively slowly under non-oxidising conditions or with limited supply of oxygen and relatively rapidly in presence of oxygen or air. Cast iron, on the other hand, corrodes relatively more in the absence of air or oxygen, or with limited supply, and relatively less in the presence of air or oxygen compared with purer irons. Solution pressure, while fundamental in corrosion phenomena, is not as a rule the determining factor. This is shown by aluminium corroding not only less than iron, but also less than copper under similar conditions.—J. W. D.

Iron and steel; Rates of solution of — in non-oxidising and oxidising acids. W. D. Richardson. *Amer. Inst. Chem. Eng.*, June, 1920. [Advance copy.] 12 pages.

RELATIVELY pure iron dissolves at a low rate in non-oxidising acids such as N/1 sulphuric and hydrochloric acids, while less pure irons such as cast iron, white iron, and malleable iron dissolve at a relatively high rate. Cast steel dissolves at a rate intermediate between the two. In an oxidising acid such as N/1 nitric acid, the rates of solution of the metals are reversed, pure iron dissolving at a higher rate than cast iron, steel again being intermediate. Difficulties were experienced in producing exactly similar conditions during solution, the temperature of 16° C. used with the sulphuric acid rising to 39° C. with nitric acid. The results obtained, however, appear to indicate a general rule. Air agitation of the acids accelerates the rate of solution, but not to the extent anticipated.

—J. W. D.

Corrosion; Suggested basis for an index of — for iron and steel. W. D. Richardson. *Amer. Inst. Chem. Eng.*, June, 1920. [Advance copy.] 8 pages.

THE index of corrosion (C) recommended represents the relation between the loss per sq. cm. per hr. in N/1 nitric acid (O), and the similar loss in N/1 sulphuric acid (H). The index cannot yet be expressed as a simple ratio $C=O/H$ owing to the small amount of data available. It has to be considered as really consisting of two indices written together as a ratio for convenience, but subjects for separate consideration. H the index for one metal ought to be compared with H the index for another, and similarly the two O indices.

—J. W. D.

Tungsten, molybdenum, and vanadium; Estimation of — in their ferro-alloys. Mitt. Chemikerausschuss Ver. deuts. Eisenhüttenleute. *Stahl u. Eisen*, 1920, 40, 857—858.

Tungsten in ferro-tungsten.—0.5 g. of the finely-powdered alloy is roasted in a platinum crucible, the residue fused with 6 g. of sodium potassium carbonate, and the melt leached with water. The residue is filtered off, washed, and again fused etc. as before. The united filtrates are boiled with ammonium carbonate and alcohol to precipitate silica, alumina, and manganese oxide; the solution is allowed to stand for 2 hrs., then filtered and the precipitate washed with very dilute sodium carbonate solution. The filtrate is just neutralised with nitric acid, using methyl orange as indicator, boiled to expel carbon dioxide, and treated hot with a slight excess of mercurous nitrate, then with ammonia, drop by drop, until the precipitate becomes permanently grey. The precipitate is filtered off, washed with dilute mercurous nitrate, and ignited. The residual tungsten trioxide is heated

successively with hydrofluoric acid and ammonium chloride till of constant weight. If chromium is present, the weighed oxide is fused with alkali carbonate, the melt leached, and the chromium determined in the solution with thio sulphate. *Molybdenum in ferro-molybdenum*.—1 g. of the finely-divided alloy is dissolved in nitric acid (sp. gr. 1.2), any residue being fused with sodium potassium carbonate and the solution of the melt added to the main solution, which is then evaporated to fumes with 5 c.c. of strong sulphuric acid. The mass is treated with water, a considerable excess of ammonia added, and the liquid set aside for 2 hrs. in a warm place. It is then cooled, diluted to 1 l., 200 c.c. filtered through a dry paper and saturated with hydrogen sulphide. The light red solution is just acidified with dilute sulphuric acid (1:5) and allowed to stand for 2 hrs.; the precipitate is filtered off, washed first with hydrogen sulphide water containing sulphuric acid, then with dilute alcohol, dried, ignited apart from the paper, and the residue weighed as MoO_3 . *Vanadium in ferro-vanadium*.—0.3 g. of the finely-powdered alloy is dissolved in 20 c.c. of nitric acid (sp. gr. 1.2), and the solution evaporated to fumes with 20 c.c. of concentrated sulphuric acid. After cooling, the residue is evaporated three times with 25 c.c. of concentrated hydrochloric acid, the last evaporation being prolonged until the sulphuric acid fumes strongly. The flask is kept covered with a clock-glass during these operations to prevent re-oxidation. The final liquor is diluted with 300 c.c. of air-free water containing 15 c.c. of phosphoric acid (1:3) and the solution titrated at $60^\circ\text{--}70^\circ\text{C}$. with permanganate, which should be standardised against ferro-vanadium of known vanadium content or against pure vanadic acid.—A. R. P.

Copper assay; Electrolytic —: a new modification. F. G. Hawley. Eng. and Min. J., 1920, 110, 162—165.

From 1 to 3 g. of the sample is mixed with 1 g. of sodium bisulphate, 1 g. of ammonium sulphate, and 5 c.c. of 70% sulphuric acid; 5 c.c. of nitric acid saturated with potassium chlorate is added, and, after standing for a few minutes, a further 10 c.c. The mixture is digested warm for a short time, then evaporated until strong fumes are evolved and the mass has become pasty. After cooling, 1 c.c. of water is added, followed immediately by 50 c.c. of dilute ammonia (ammonia 2 l., water 4 l., ammonium nitrate 100 g.); the liquid is well stirred, heated to boiling, cooled slightly, 5 c.c. of strong ammonia added, and the precipitate filtered off, washed once with water, once with ammonia (1:1), and once again with water. The filtrate is boiled to expel ammonia, cooled, and treated with 3 c.c. of sulphuric and 3 c.c. of nitric acid. Meanwhile the precipitate is dissolved off the filter with dilute nitric acid, the solution made ammoniacal, a few drops of 2% potassium cyanide added, and the warm solution, without filtration, electrolysed for $\frac{1}{2}$ hr. at 0.2 amp., using a rotating cathode. The beaker is then removed and replaced by that containing the bulk of the copper, the current is switched on in the opposite direction to re-dissolve the small amount of impure copper that was deposited from the iron precipitate, then switched back to the original direction and the electrolysis continued for 1—1½ hr. at 1—1.5 amp., and finished as usual. Hydrochloric acid should be used in dissolving oxidised ores, and, if molybdenum is present, a small amount of a soluble lead salt should be added before the ammonia solution.—A. R. P.

Brasses; Special —. L. Guillet. Comptes rend., 1920, 171, 172—173. (Of J., 1906, 510, 813; 1913, 90, 913; 1920, 157A, 269A.)

BRASSES containing cobalt are in no way superior to those containing nickel, and consequently have

no industrial importance. When chromium is introduced into brasses, a portion of it enters into solution in the constituents of the brass, but another portion forms a special constituent, probably metallic chromium, which diminishes the value of the alloy. Silver has no very pronounced action on the structure of a copper-zinc alloy, but gold, on the contrary, gives a fictitious copper content (J., 1906, 540) markedly greater than the real content. —W. G.

Brasses; Special —. L. Guillet. Mem. Soc. Ing. Civils de France, 1920, 73, 154—182.

A FULL account of investigations, the chief results of which have been published previously (J., 1906, 540, 813; 1913, 90, 913; 1914, 358; 1918, 338A; 1920, 157A, 269A; also preceding abstract).

Anode corrosion of lead. Brown and others. See XI.

PATENTS.

Steel melting plant. E. and W. Waring. E.P. 147,244, 7.2.19.

A MIXTURE of iron ore and coal is passed through a producer chamber on a conveyor and delivered with lime to a cupola from which the material is conveyed to a furnace, the gases from which pass through the cupola to a combustion chamber in which a part of the conveyor and a boiler are situated. The gases from the producer are conveyed to tuyères in the producer chamber and furnace.—J. W. D.

Iron; Production of —. A. Jackson. E.P. 147,999, 25.4.19.

REFINED iron containing Si 0.3—0.6%, total C 1.5—2.5%, P 0.3—0.6%, and less than 0.1% S, is prepared by melting in a cupola a mixture of steel scrap and selected pig iron in suitable proportions according to analysis.—J. W. D.

Ferro-alloys; Production of —. H. L. Suhman and W. B. Ballantine. E.P. 145,925, 9.5.19.

CASTINGS resistant to rust and corrosion are produced by reducing a pure compound of iron and chromium (e.g., oxides) with a thermo-reducing agent containing white iron, or forge scale containing silicon, or calcium silicide, so that silicon is introduced into the alloy during reduction.

—J. W. D.

Chromium-containing [iron] alloys; Process of producing —. F. A. Fahrenwald. U.S.P. 1,346,187, 13.7.20. Appl., 25.8.19.

FERROUS metal ores are mixed with just sufficient carbon to reduce all the metallic constituents, and the mixture is first heated for a long time to a temperature sufficiently high to carry out the reduction without reducing the silica in the charge; finally, the heat is raised until the reduced metal melts and the unreduced constituents are slagged off.—A. R. P.

Firearm and [iron and copper] alloys for making same. F. A. Fahrenwald. U.S.P. (A) 1,346,188, (b) 1,346,189, (c) 1,346,190, and (d) 1,346,191, 13.7.20. Appl., (A) 25.8.19, (n) 15.10.19, (c) (d) 15.12.19.

(A) An alloy of one or more iron group metals with one or more chromium group metals. (b) An alloy of approximately 36% Ni and 64% Fe. (c) An alloy of copper and not less than 25% Ni. (n) An alloy of iron with at least 30% of one or more metals at the iron group.—A. R. P.

Metallic powders; Production of —. E. Odam. E.P. 129,631, 21.6.19. Conv., 10.7.18.

GRANULATED metal, waste metal cuttings, etc., are reduced to powder by causing them to flow under

the action of centrifugal force into a conduit which directs the material between balls and the races in which they run. The material is passed several times successively through the device before being discharged.—J. W. D.

Crucible and like furnaces. J. A. Gaskill. E.P. 132,266, 3.9.19. Conv., 3.9.18.

A CRUCIBLE for melting steel, iron, or other metals, reducing refractory ores, or annealing and heat treating metal articles, is mounted on supports within a refractory combustion chamber, closed at the bottom by hinged doors, and at the top by a cover having a central vent opening. The combustion chamber is surrounded by a jacket into which the air for combustion passes tangentially at the bottom, and is preheated while passing round the combustion chamber to the outlet at the top. Two burners for fuel gas or oil project tangentially into the combustion chamber at opposite sides near the bottom. The side wall of the combustion chamber projects inwards at its middle zone, so that the combustion products are deflected into contact with the crucible and are then allowed to expand before escaping at the top.—W. F. F.

Regenerators for smelting furnaces and the like. P. Kühn. E.P. 138,103, 20.1.20. Conv., 4.5.18.

THE regenerators are provided with gratings in two compartments inclined to one another, the floor of the compartment nearer the furnace sloping downwards to the rear. This arrangement prevents clogging of the gratings when coal dust is used as fuel.—J. W. D.

Furnaces for the heat treatment of metal articles. A. Hardy, J. H. Hunt, and M. Wigglesworth. E.P. 145,958, 5.6.19.

GAS from a producer passes into a horizontal longitudinal flue below the horizontal heating chamber. This flue is provided with inclined outlets arranged alternately on opposite sides and the gas on leaving each outlet meets a stream of preheated air. The burning gas from each outlet passes through separate transverse flues, extending completely around the heating chamber. The hot gas then passes through tortuous passages adjacent to the passages through which the air supply for combustion is passed to preheat it.—W. F. F.

Alloy; Metal — for the armourings of electric cables. D. Stenquist. E.P. 136,143, 9.10.19. Conv., 5.12.18.

THE alloy is composed of lead and 0.01 to 0.1% of magnesium.—B. N.

Metal alloy. A. E. Farmer. E.P. 145,956, 4.6.19. THE alloy consists of copper, 53 lb., aluminium 0.25 lb., tin 0.25 lb., spelter 28 lb., and nickel 25 lb. The copper and 23 lb. of the spelter may be replaced by 75 lb. of 70–30 cartridge metal.—W. F. F.

Aluminium castings; Production of —. Metall-industrie Schiele und Bruchsal. E.P. 137,325, 2.1.20. Conv., 18.2.18.

IN the production of aluminium castings in metal moulds the surfaces of the moulds and their metal or sand cores are coated before each pouring with a varnish containing either aluminium or an aluminium alloy, and then slowly heated to 400° C. to burn off organic matter and leave an even coating of aluminium which prevents oxidation and ensures clean castings. The moulds and cores are then fitted together, heated to 550°–700° C., and the aluminium cast in them in the usual manner.—A. R. P.

Castings; Process of making —. Z. Jeffries, Assr. to Aluminium Castings Co. U.S.P. 1,347,481, 20.7.20. Appl., 24.9.17.

INTRICATE castings of aluminium alloys or other

metals having high coefficients of expansion are prepared by casting the molten metals into a permanent mould formed of metal having approximately the same coefficient of expansion as the metal of the casting, and a high coefficient of thermal conductivity compared with iron.

—J. W. D.

Ores; Concentration of —. L. A. Wood, and Minerals Separation, Ltd. E.P. 145,852, 23.3.19.

ORES containing copper sulphide and/or carbonaceous material, and/or molybdenite may be separated from other ingredients such as iron, zinc, or lead sulphides by the froth flotation process using frothing agents such as amyl and butyl alcohols, camphor, furfural, phenol, cresol, aniline, toluidine, picoline, lutidine, or aqueous extracts of commercial oils, such as wood tar or eucalyptus oil. The differential separation effected by these substances is improved by the addition of alkali silicates, hydroxides, or carbonates.—W. F. F.

Ores; Concentration of — and apparatus therefor. Minerals Separation, Ltd. From E. H. Emerson. E.P. 145,870, 1.4.19.

THE ore pulp is mixed with a mineral-frothing agent, and is supplied to the top of a separating vessel placed at the top of an inclined trough. The pulp is delivered into a funnel having a wide stem projecting downwards into the vessel, and the mixture is aerated and agitated by a jet of water and air which is projected downwards into the stem of the funnel. The froth carrying the mineral particles overflows at the top into the inclined trough. The residue passes from the bottom of the separating vessel to the top of a second separating vessel, and so on through a series of vessels arranged at progressively lower levels along the inclined trough. The mixing jet for each vessel is produced by a water-air injector, and the jets are directed against a transverse baffle at the centre of each separating vessel.—W. F. F.

Flotation process. R. Gahl, Assr. to Pneumatic Process Flotation Co. U.S.P. 1,346,819, 20.7.20. Appl., 10.12.18.

ADDITIONAL sand substantially free from slimes is introduced into the normal pulp and the mixture subjected to froth flotation.—J. W. D.

Corrosion of metallic surfaces; Composition for preventing —. C. A. Allison. From Naigai Kagaku Seihin Kabushiki Kaisha. E.P. 146,676, 15.5.19.

A COMPOSITION for preventing oxidation of metallic surfaces immersed in liquids consists of borax, 8–15 pts., dextrin 2–3 pts. An addition of 1% of the above to ink made from tannic and sulphuric acids prevents corrosion of pens. The composition is also applicable for protecting metal articles immersed in disinfecting solutions such as mercuric chloride, and for preventing corrosion of steam boilers.—W. F. F.

Rust-preventing treatment. W. R. Swan, Assr. to J. J. Woolverton. U.S.P. 1,346,473, 13.7.20. Appl., 8.1.20.

IRON and steel articles are heated in a sealed chamber, the chamber is then partially evacuated, and the vapour of a non-corrosive substance admitted.—A. R. P.

Electrolysing cobalt solutions. E. B. Cutten. U.S.P. 1,344,869, 29.6.20. Appl., 20.10.19.

COBALT is deposited by electrolysing a solution of cobalt sulphate, which is maintained neutral by the action of a reagent that forms an insoluble and innocuous precipitate with the liberated sulphuric radical.—B. N.

Metals [copper]; Process of extracting — from their ores. W. E. Greenawalt. U.S.P. 1,315,846, 6.7.20. Appl., 13.12.15. Renewed 15.9.19.

COPPER ores are leached with an acid solution to dissolve the copper; the rich solution is drawn off and electrolysed to deposit the copper and regenerate the acid. The gangue is washed, the washings treated with hydrogen sulphide, and the precipitated copper sulphide digested with the electrolyte to reduce the metallic salts therein to their lower state of oxidation.—A. R. P.

Nickel ores; Process of treating —. M. H. Caron, Assr. to Clevenger and Caron. U.S.P. 1,346,175, 13.7.20. Appl., 19.5.19.

NICKEL silicate ores are subjected to a preparatory reducing roast, the reduced ore being cooled under non-oxidising conditions.—A. R. P.

Metal from ores etc.; Apparatus for extracting —. H. H. Godfrey. U.S.P. 1,347,026, 20.7.20. Appl., 4.8.19.

THE apparatus consists of an ore concentrating shaking table inclined longitudinally and transversely, covered with a cathode, and an anode spaced above the cathode.—J. W. D.

XI.—ELECTRO-CHEMISTRY.

[*Electrical precipitation.*] **Motion of droplets and particles in the field of the corona discharge.** R. C. Tolman and S. Karrer. Chem. and Met. Eng., 1920, 22, 1203—1206.

By photographing the form of a water jet arranged within a precipitation chamber containing a central wire between two parallel sheet metal plates, the jet being discharged parallel to the central wire, it is shown that there are four methods whereby particles in the field of a corona discharge may ob-

tain charges of electricity, namely, by induction, by conduction of electricity from the earth, by the adsorption of ions present in the corona field, and by actual contact with an electrode. The motion of the particles is determined by the charge received and by the potential gradient of the field. The space charge in the major part of the corona discharge is of the same sign as the central wire. It is believed that the adsorption of ions having the same charges as the central wire is the underlying process in the action of Cottrell precipitators.

—J. S. G. T.

Lead; Anode corrosion of — in sodium hydroxide solutions. O. W. Brown, C. O. Henke, and L. T. Smith. J. Phys. Chem., 1920, 24, 367—378.

THE amount of corrosion of lead anodes in the electrolysis of sodium hydroxide solutions rapidly increases with increasing temperature; thus using a solution of 152 g. of sodium hydroxide per l. the amount of corrosion is 4.5% of the theoretical at 20° C., 98.3% at 60° C., and theoretical at 75° C. At all temperatures the corrosion increases, with increasing concentration of the sodium hydroxide, to a maximum which it reaches with 152 g. per l. and then falls with further increase in concentration. Thus at 60° C. the following fractions of the theoretical amount of corrosion are found with the concentration given: 35 g. per l., 5.7%; 71 g., 49.3%; 110 g., 96.4%; 152 g., 98.3%; 192 g., 58.5%; 304 g. per l., 37.7%. The current efficiency increases rapidly with increase in temperature, this being especially marked for solutions containing 152 g. per l. and a current density of 4 amps. per sq. dm. There is a 100% corrosion when the bath tension is low (0.2—0.3 volt), and a low corrosion when the voltage is high (3.2 volts). When the anode is corroding properly the discharge potential is about 0.2 volt, but when it ceases to corrode the discharge potential rises to -1.317 volt.—J. F. S.

Salts; Electrical conductivity of mixtures of fused and solid —. C. Sandonnini. Gaz. Chim. Ital., 1920, 50, I., 289—321.

THE conductivities of various binary mixtures of salts, some of which merely mix while others form compounds, have been measured. For the fused mixtures the equivalent conductivity—in which allowance is made for the slight change in specific gravity occurring on mixing—is always less than the value calculated from the law of mixtures; the divergences are the more marked for those pairs of salts with which compounds exist in the fused mass, but the conductivity isotherms in general exhibit no singular points corresponding with the composition of such compounds, although for KCl—CaCl₂ this is approximately the case. XII.—FATS; OILS; WAXES.

Linseed oil; Hexabromide test of the purity of —. Amer. Soc. Testing Materials. Circ. No. 99. Educat. Bureau, Paint Manufacturers' Assoc., U.S.A., July, 1920. 16 pages.

In Bailey's modification of Steele and Washburn's method (J., 1920, 197 A) the linseed oil fatty acids are prepared in an atmosphere of carbon dioxide. 1 g. is dissolved in 25 c.c. of ether, which has been purified, dried, and saturated with linolenic hexabromide at 0°–2° C., in a weighed centrifuge tube (1 in. diam. × 5 in. long), which is then placed in a freezing mixture at about –5° C. (crushed ice and dilute hydrochloric acid). Freshly-prepared bromine solution (5 c.c. in 25 c.c. of glacial acetic acid) is added, drop by drop, until a deep red coloration is produced. The tube is left for about 14 hrs. in an ice-chest, then centrifuged, cooled in an ice-bath, and the ether decanted. The deposit is washed with 20 c.c. of the prepared ether at 0° C. and the tube again centrifuged, and this washing and decantation repeated twice more. Finally the tube is warmed in water at 60° C. until most of the ether has evaporated and attached to a vacuum pump showing a pressure of 30–40 mm., and after 15 mins. is removed from the water bath, allowed to stand for 15 mins. and weighed. The results are somewhat lower and less concordant than those given by Steele and Washburn's method. (Cf. J., 1920, 417 A.)—C. A. M.

Tung oil; Standard specifications for the purity of raw —. Amer. Soc. for Testing Materials. Circ. No. 100. Educat. Bureau, Paint Manufacturers' Assoc., U.S.A. July, 1920. 12 pages.

It is proposed that raw tung oil shall answer to the following requirements:—Sp. gr. 15.5°/15.5° C., 0.943–0.939; acid value, 6 (max.); saponif. value, 195–190; unsaponif. matter, 0.75% (max.); n_D^{25} = 1.520–1.515; iodine value (Hübl 8 hrs.), 165 (min.); and heating test, 12 mins. (max.). The following modification of Browne's heating test is prescribed:—Test tubes for the oil should be 15 cm. by 16 mm., and be closed by a cork through which a glass rod 3 mm. in diam. can move easily. A beaker (800 c.c.), 15 cm. high and 10 cm. in diam., is filled to 7.5 cm. with cottonseed or soya bean oil, and in this is suspended a thermometer at 1.5 cm. from the bottom. The oil is heated, and at 293° C. (560° F.) two test-tubes containing respectively 5 c.c. of the tung oil and 5 c.c. of a control sample are introduced so that the bottom of each tube is level with the lowest part of the thermometer bulb. The source of heat is removed for about 45 secs. and then replaced, and the temperature maintained at 282° C. (540° F.) as constantly as possible. After 9 mins. the glass rods are raised at intervals of ¼ min., and a note taken of the time required for each sample to set firmly. The average time of setting of pure American pressed tung oil was 9½ mins., whilst the same oil with 5% of soya bean oil required 10½ mins. to set.—C. A. M.

Yeast fat; Nature of —. J. S. MacLean and E. M. Thomas. Biochem. J., 1920, 14, 483–493.

CRUDE yeast fat is a brown liquid with a high iodine value and a low saponif. value, and has a large proportion (25–45%) of unsaponifiable matter. It may contain as much as 20% of a sterol, apparently identical with ergosterol, partly in the free state and partly as fatty acid esters. Palmitic, oleic, and linolic acids have been identified with certainty in yeast fat, and there is evidence for the presence of lauric and possibly arachidic acids. (Cf. J.C.S., Sept.)—W. G.

Cockle-burr oil. A new seed oil. L. B. Rhodes. J. Amer. Chem. Soc., 1920, 42, 1507–1508.

THE burrs were of the species *Xanthium echinatum*.

The kernels freed from the black shucks amounted to 30.69% of the burrs, and contained moisture, 6.95–7.22%; crude protein, 40.34–40.53%; oil, 29.78–29.89%; crude fibre, 2.47–2.58%; ash, 5.42%. When cold pressed they gave a light yellow sparkling oil, with a pleasant odour and a nutty flavour. It had sp. gr. at 15.5° C. 0.9251; $n_D^{15.5}$ = 1.4773; Zeiss butyrometer reading at 20° C. 1.4771, 40° C. 1.4691; solidif. pt. –18.0° C.; iodine value, (Hanus) 140.8; saponif. value 190.2; Reichert-Meissl value 0.233; Hehner value 89.7; acetyl value 10.6; m.pt. of fatty acids 19.0° C. The oil is a drying oil. The kernel meal and the press cake were both highly toxic to guinea-pigs.—W. G.

"Stearic" acids; Explanation of uniform composition of —. B. H. Nicolet. J. Ind. Eng. Chem., 1920, 12, 677–679.

COMMERCIAL "stearic" acids were found to agree within 0.5° in solidif. pt. (55.18°–55.66° C.) after allowing 0.2° C. for each 1% of oleic acid calculated from the iodine value. In the case of mixtures of pure stearic and palmitic acids the solidif. pt. curve falls continuously from 100% stearic acid to a point B (55° C. 50% palmitic acid), then rises to a maximum at C (55.4° C. 55% palmitic acid), falls to D (about 72% palmitic acid), and finally rises normally to 100% palmitic acid. It is concluded that in accordance with the behaviour of solid solutions the commercial "stearic" acids examined have been derived from mixtures containing between 53 and 72% of palmitic acid in their saturated fatty acids, so that their composition would fall within the section of the curve from B to D, and on pressing would approach the composition corresponding to the maximum point C, and thereafter show no further alteration.—C. A. M.

Fatty acids; Synthesis of — from paraffin wax and other petroleum fractions. K. Löffl. Chem.-Zeit., 1920, 44, 561–562.

In the catalytic oxidation of petroleum hydrocarbons (cf. J., 1920, 459 A, 521 A) the best yields of fatty acids are obtained with lead or mercuric compounds, which apparently dissolve completely in the products of oxidation. The best results are obtained by oxidising at 115°–120° C., under a pressure of 3 atm. and with agitation for about 7 hrs., in the presence of water, which is an essential factor. Alkalis have not the catalytic influence claimed by Schaal and by Franck (J., 1920, 395 A). The oxidation products (98–120%; av. 106–110% on the original material) consist of about 7–20% of water, 25–40% of lower fatty acids, with small amounts of aliphatic aldehydes and ketones, and 78–50% of higher fatty acids and 10–15% of unsaponifiable matter. They may be fractionated by distillation (up to 200° C.) with superheated steam and then by distillation with steam *in vacuo*. The unsaponifiable hydrocarbons may be separated by fractional precipitation with alcohol, alcohol-ether, and alcohol-ethyl acetate. The fatty acids mixed with 10–20% of tallow or coconut oil fatty acids yield satisfactory soaps.—C. A. M.

Fats; Comparison of different methods for determining the iodine value of —. T. Sundberg and M. Lundborg. Z. Unters. Nahr. Genussm., 1920, 39, 87–95.

THE Hanus method gives results which agree with those found by the Hübl method, whilst considerably higher values are found by the Wijs method and slightly lower by Winkler's method. In the case of fats or oils with high iodine values the Hübl method gives results which are nearest to the calculated values, e.g., linolic acid, 181.1 (calculated), 194.3 (Hübl), and 201.1 (Wijs).—W. P. S.

Cottonseed oil. Daniels and Loughlin. See XIXA.

PATENT.

Linseed oil substitute. U.S.P. 1,347,074. See XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Air in paint and varnish containers; Composition of —. H. A. Gardner and T. M. Rector. Paint Manufacturers' Assoc., U.S., and National Varnish Manufacturers' Assoc. Circ. 103, Aug., 1920. 2 pp.

The oxygen in the air contained in the space above the liquid in a sealed can of paint or varnish is found to be completely absorbed by the drying oils in a period of two weeks.—A. de W.

PATENTS.

Phenolic condensation product; Process of producing a —. Method of preserving infusible phenolic condensation products from discoloration. L. V. Redman, A. J. Weith, and F. P. Brock, Assrs. to Redman Chemical Products Co. U.S.P. (a) 1,345,694 and (b) 1,345,695, 6.7.20. Appl., (a) 16.9.18 (Renewed 12.5.19), (b) 24.7.19.

(A) To obtain a phenolic condensation product without the aid of a condensing agent, a solution of formaldehyde and a phenolic substance largely in excess of the formaldehyde is boiled until the formaldehyde is substantially eliminated from the supernatant aqueous layer which forms, the aqueous layer is discarded, the viscous gummy lower layer is concentrated by further heating, then mixed with a solution of formaldehyde in lesser proportion than in the first step, poured into moulds, caused to set at a temperature below 100° C., removed from the moulds, and hardened to an infusible and substantially insoluble condition by prolonged heating below 100° C. (b) An infusible and practically insoluble phenolic condensation product of the transparent order is preserved in a medium which is inert thereto when exposed to the action of sunlight. —A. de W.

Linseed oil substitute and process of making same. R. C. Bone, Assr. to M. A. Esteve. U.S.P. 1,347,074, 20.7.20. Appl., 23.3.18.

A MIXTURE of 60 pts. of kerosene and 40 pts. of lubricating oil is mixed with 10 pts. of rosin, the mixture heated to boiling for approximately 50 mins., agitated, 2½ pts. of manganese hydroxide added with stirring and the mixture boiled for about 15 mins., the supernatant liquid withdrawn, about 1 pt. of red-rod oil added, and the mixture allowed to rest for about 12 hrs.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; New elasticity testing machine for soft (vulcanised) —. A. Schob. Gummi-Zeit., 1920, 34, 995—997.

A METAL bob supported pendulum-fashion, with an effective weight of 200 g., falls through a vertical height of 25 cm., and at the bottom of its swing strikes a disc of the rubber, 6 mm. thick and approximately 36 mm. diam., supported vertically against the heavy base of the machine. The extent of the recoil of the pendulum is read from a graduated arc and indicates the relative elasticity of the material of the disc. The test pieces are dusted with tale before use and the temperature is kept as near 20° C. as possible. Results are quoted illustrating the effect of different temperatures and of different thicknesses of material.

—D. F. T.

PATENT.

Vulcanising dissolved caoutchouc; Process for —. S. J. Peachey. E.P. 146,731, 2.8.19.

RUBBER in solution in e.g. benzene, naphtha, carbon bisulphide, etc., can be vulcanised at ordinary temperatures by treatment with sulphur in the presence of nitrosobenzene or similarly constituted nitroso-hydrocarbons of the cyclic series.—A. de W.

XV.—LEATHER; BONE; HORN; GLUE.

Tan liquors; Determination and control of acidity in —. W. R. Atkin and F. C. Thompson. J. Soc. Leather Trades' Chem., 1920, 4, 143—152.

A RAPID method is described for determining the actual hydron concentration of tan liquors, by the use of bromophenol blue, which changes colour from $pH=2.8$ to $pH=4.6$. The colour observed through two test-tubes, one containing the tan liquor and the other the standard acid solution and indicator, is matched through a yellow screen against two other tubes, one containing water and the other the indicator, to which is added increasing amounts of tan liquor until the matching is complete. The quantity of tan liquor in the first tube is increased to correspond with that in the last one, and thus allowance is made for the colour of the tan solutions. A simple calculation shows the acid present in the amount of tan liquor necessary to match the standard. For control purposes the tan liquor can be titrated with a standard solution of acid until its acidity reaches that required as shown by the test. Figures are given for various tan liquors and comparisons are made with figures obtained by Procter's lime water method.—D. W.

Leather; Estimation of hide substance in —. P. Chambard. J. Soc. Leather Trades' Chem., 1920, 4, 159—161.

DISCREPANCIES in hide substance determinations by the Kjeldahl method have been attributed to incomplete combustion of organic matter following the use of an insufficient quantity of potassium permanganate and also the difficulty of obtaining an average sample. The author recommends that the leather should be very finely cut up, and 2.8 g. heated with 25 c.c. of sulphuric acid, 12 g. of pure potassium bisulphite, and 0.6 g. of anhydrous copper sulphate. The mixture is boiled for 2½ hrs. With 9 different samples of leather the method gave higher figures than those obtained by oxidising with permanganate.—D. W.

Glues and gelatins; Properties and constitution of —. R. H. Bogue. Chem. and Met. Eng., 1920, 23, 5—12, 61—66, 105—109, 154—158, 197—203.

THERE is no variation in the viscosity of solutions of normal glues with time up to 90 mins. Vigorous agitation of a glue or gelatin solution results in a lowering of the viscosity as also does prolonged heating. Dehydration produces a reversion of "soluble" gelatin to "insoluble" collagen. At temperatures well above the melting point the viscosity increases nearly as a logarithmic function of the concentration and varies inversely as the temperature. Addition of formaldehyde, chloral hydrate, and alums increases the viscosity. Alums have no effect upon the gel strength, but the other substances decrease the strength. Nearly all electrolytes produce a lowering in gel strength, but their effect upon viscosity may be continually to increase, continually to decrease, or first to increase and later to decrease the viscosity. It is probable that the colloid aggregates of protein molecules are united into a "streptococcic thread" which would account more adequately than the older theories for the various properties of gelatin. If the gel strength remains constant the viscosity varies as the melting point, and if the normal viscosity remains constant the gel strength varies as the

melting point. There appears to be no relation between the proximate constitution of glues and their gel strength and viscosities except that the water content of the air-dry glue is proportional to the gel strength. The water-retaining capacity of glues and gelatins is therefore controlled by the same factors as determine the gel strength. This varies directly as the protein nitrogen content and indirectly as the proteose and peptone nitrogen in all glues and gelatins. The amino-acid nitrogen is greater in bone glue than in hide glues, and tends slightly to increase with decrease in gel strength. The melting point and therefore the viscosity of a glue is determined normally by the balance between the protein content and that of its hydrolysed products, but at any given uniform gel strength the melting point and viscosity will depend upon the ratio of large to small sized molecules within the protein group. As the boiling of a glue progresses it is probable that some foreign substances as chondridin, keratin, mucin, etc., become hydrolysed and enter the solution, causing variations in the different grades. Hide and bone glues differ from each other in chemical constitution. Fish glue corresponds more closely in its composition to low-grade bone glue than to any other. Fish glue and isinglass differ from animal glues in their low content of proline, oxyproline, and tryptophane. The strength of a glue in service is a function of the gel strength and of the viscosity, and directly proportional to the melting point. The melting point method for evaluation of glues is recommended as yielding a true index of actual strength in service. A very full bibliography on the subject is given.

—D. W.

Gelatin solutions; Acidity of ash-free and of commercial — H. E. Patten and T. O. Kellems. *J. Biol. Chem.*, 1920, 42, 363—366.

The isoelectric point of ash-free gelatin lies at $p_H = 4.8$, corresponding to a hydrogen-ion concentration of 1.59×10^{-5} , and that of commercial gelatin at $p_H = 5.64$, corresponding to a hydrogen-ion concentration of 2.28×10^{-5} .—W. G.

Leather; Process of making — A. Rogers. U.S.P. 1,346,385, 13.7.20. Appl., 5.5.20.

HIDES and skins are subjected to a mineral tannage followed by treatment with shark liver oil.—D. W.

XVI.—SOILS ; FERTILISERS.

Protozoa in the soil; A method for estimating the number of active — D. W. Cutler. *J. Agric. Sci.*, 1920, 10, 135—143.

THE total number of protozoa in the soil is first found by a dilution method. A fresh portion of the

soil is then treated with sufficient 2% hydrochloric acid to neutralise the carbonate present and leave an excess of acid, and the sample is left overnight. By this means all the active forms are killed. A second count by the dilution method gives the number of cystic protozoa in the soil, and the number of active forms can then be found by difference.—W. G.

Arable soil; Measure of the ammonifying power of — R. Peretti. *Att. R. Accad. Lincei*, 1920, 29, i., 251—256.

THE best conditions for carrying out the solution method of determining the ammonifying power of arable soil are as follows:—10 c.c. of 1.5% peptone solution is treated in a test-tube with 5 c.c. of the solution obtained by steeping 50 g. of the soil in 500 c.c. of well-water. The tube is kept in a thermostat at 20°—25° C. for 4 days, after which the ammonia produced is estimated by distilling the contents of the tube in presence of magnesia. The mean of four separate determinations is taken.

—T. H. P.

Cyanamide in the soil; Mechanism of the decomposition of — G. A. Cowie. *J. Agric. Sci.*, 1920, 10, 163—176. (*Cf. J.*, 1919, 380 A.)

CYANAMIDE is first broken down to urea in soils by a purely chemical change, and then the urea is converted into ammonia by soil organisms. In sterile soils (previously heated to 120° C. or 135° C.) only the first change occurs and there is an accumulation of urea. In the case of an inert sand in which the cyanamide did not undergo decomposition, it was found that the addition of a zeolite, prehnite, resulted in the conversion of the cyanamide into urea. Cyanamide does not appear to break down in this manner in peat and fen soils; in these it gives rise to a relatively small production of urea under normal conditions.—W. G.

Humic acid. F. Fuchs. *Chem.-Zeit.*, 1920, 44, 551.

THE results obtained with humic acid prepared from peat by means of alkali indicated that it was a true acid, with molecular weight of about 680. It formed simple salts with different metals, and was precipitated by inorganic or organic acids. When treated with sodium sulphide or sulphite it yielded a soluble sulphite compound which reacted with aniline and other organic bases. (*Cf. J.C.S.*, Sept.)—C. A. M.

Plant growth; Action of chromium and manganese on — T. Pfeiffer, W. Simmermacher, and A. Rippel. *Bied. Zentr.*, 1920, 49, 259—263.

EXPERIMENTS on oats and barley treated with an ordinary fertiliser and with small proportions of chrome iron ore or potassium bichromate failed to reveal any beneficial effect of the chromium, and similar experiments on oats treated with manganese sulphate indicated that the effect of the manganese is at most very minute.—T. H. P.

Iron; Toxicity of — [to plants] and the antitoxic properties of copper with respect to ferrous salts. L. Maquenne and E. Demoussy. *Comptes rend.*, 1920, 171, 218—222.

FERROUS salts are much more toxic to young plants than ferric salts. Any condition which tends to facilitate the oxidation of ferrous salts will consequently diminish their toxicity. This explains the beneficial effect of copper sulphate in diminishing the toxicity of ferrous salts to plants, since the former has been shown to exert a catalytic effect on the oxidation of the latter.—W. G.

Manurial composts; Occurrence and nature of the plant growth-promoting substances in various organic — F. A. Mockridge. *Biochem. J.*, 1920, 14, 432—450.

LEAF-MOULD, fresh and well-rotted stable manure,

as well as well-manured fertile soil, contain, in varying proportions, water-soluble substances, which are effective as plant growth-promoting substances, as is shown by the effect of their aqueous extracts on the development of plants of *Lenina major*. In all cases the extract of rotted manure was more effective than that of fresh material. All these materials contain appreciable quantities of nucleic acid and its derivatives in various stages of decomposition, and the greater the bacterial decomposition of the material concerned, the greater is the resolution of the original nucleic acid into its free bases.—W. G.

XVII.—SUGARS; STARCHES; GUMS.

Glucosan. A. Pietet and P. Castan. *Comptes rend.*, 1920, 171, 243—245. (See *Gelis ibid.*, 1860, 51, 331.)

When dextrose is heated at 150°—155° C. under a pressure of 15 mm. it gives a crystalline anhydride, glucosan, m.p. 108°—109° C., which is very deliquescent, gives a tribenzoyl derivative, and a sodium bisulphite compound. (*Cf.* J.C.S., Sept.) —W. G.

XVIII.—FERMENTATION INDUSTRIES.

Brewing water; Zikes' method of testing — for organisms injurious to wort. R. Heuss. *Z. ges. Brauw.*, 1920, 43, 177—180.

In Zikes' method for the biological examination of brewery water (*Allg. Z. Bierbr. Malzfabr.*, 1915, 43, 237), different volumes of the water, ranging from 50 to 0.5 c.c., are mixed with equal volumes (*i.e.*, 50 to 0.5 c.c.) of sterile brewery wort previously concentrated to twice its normal extract-content. The mixtures, contained in a series of special U-shaped apparatus of corresponding capacities, each having one limb closed and the other plugged with cotton wool, are incubated at 25° C. and observed after 7 days. The closed limb, which is completely filled with the liquid, enables the development of anaërobic organisms to be detected, whilst film-formation and the growth of aerobic organisms may be observed in the plugged limb. This method, compared with Hansen's method, has the advantage of employing a much larger volume of the water, and it also ensures that the organisms are incubated in presence of wort constituents at the normal concentration of the latter. In comparative tests of a number of waters by Zikes' and Hansen's methods the former was found the more sensitive, revealing in some of the waters the presence of organisms which Hansen's method failed to show.—J. H. L.

Inversion of sucrose; Physico-chemical investigations of the diastatic —. A. Chaudun. *Ann. Chim.*, 1920, 43, 307—319.

A FULL account of work already published (*J.*, 1918, 525 A, 600 A; 1919, 550 A, 957 A).—W. G.

Fermentation of dextrose, galactose, and mannose by Lactobacillus pentoaceticus n.sp. W. H. Peterson, E. B. Fred, and J. A. Anderson. *J. Biol. Chem.*, 1920, 42, 273—287.

Dextrose, galactose, and mannose are fermented by *Lactobacillus pentoaceticus* (*J.*, 1920, 381 A) to give lactic acid, ethyl alcohol, and carbon dioxide together with a little acetic acid, which is probably produced by secondary fermentation of the lactic acid. Dextrose and galactose are fermented at approximately the same rate and to the same extent, but mannose is fermented more slowly and less lactic acid is produced than in the case of the other two sugars.—W. G.

Worts and beers; Changes in the acidity, surface tension, and colour of —, produced by ultrafiltration. W. Windisch and W. Dietrich. *Woch. Brau.*, 1920, 37, 231—233, 237—239.

A MALT wort, the corresponding beer, and the same beer after boiling for 20 mins. under a reflux condenser, were subjected to ultrafiltration in a series of Beechhold glacial acetic acid collodion filters (*cf.* *J.*, 1906, 1177; 1907, 993) of 1, 3, 4.5, 6, and 7.5% impregnation. The original surface tension of the beer was practically the same as that of the wort; in both cases ultrafiltration through filters of increasing fineness brought the surface tension nearer and nearer to that of water. The greater part of the colouring matters of the wort and beer was removed by the 3% or 4.5% filter; only a pale yellow colour remained, resembling that of cold water extracts of ground barley, and this colour was not removed by the finest filter used (7.5%). The acidity of the wort and beer (as determined by titration) was reduced by ultrafiltration, the maximum reduction, amounting to 25—35% of the original acidity, being effected by the 7.5% filter. The 6% filter gave anomalous results, having no more effect, and in some cases less effect, than the 4.5% filter.—J. H. L.

Beer foam. H. Lüers, K. Geys, and A. Baumann. *Z. ges. Brauw.*, 1920, 43, 185—187, 193—195, 201—203. (See also Windisch and Bermann, *J.*, 1920, 462 A.)

LARGE quantities of foam from beers of various types were collected and allowed to subside in closed vessels and the resulting liquids were analysed and compared with the original beers. The most significant differences observed were as follows:—In general the foam contained rather more total nitrogen but considerably less amide nitrogen (determined by "formol-titration") than the original beer. The foam also possessed a higher ester-content and total acidity than the beer, and a volatile acidity 2—10 times as great as that of the latter. The surface tension of the foam was somewhat lower than that of the beer. The collapsed foam contained numerous flecks of coagulated protein, due to the fact that colloidal substances in liquid films tend to change from the sol to the gel state, whereby the stability of the films is much increased. Colloidal particles of nitrogenous substances of a certain size are more favourable to foam formation than larger or smaller ones. Hence the formation of head on beer may be detrimentally affected by excessive proteolysis, or by filtration through too fine a medium which retains particles of the optimal size; on the other hand, chilling may in some cases diminish head-forming power by causing particles of the optimal size to coalesce into larger particles, but this process may usually be reversed by warming again.—J. H. L.

Moselle wines; Addition of sugar to, and reduction of acidity of —. Wellenstein and Seiler. *Z. Unters. Nahr. Genussm.*, 1920, 39, 1—30.

From inferior musts, made partly from frost-bitten grapes, and possessing abnormally high acidity, it was found possible to obtain marketable wines of fine flavour by suitable treatment, including warm storage, de-acidification with calcium carbonate, re-fermentation, especially in the early part of the year after vintage, and fining with isinglass and gelatin. Contrary to a widely held opinion, long storage at 15°—16° C. tended to improve the flavour, and also accelerated maturation and reduction of acidity. Addition of sugar solution did not always reduce the final acidity in proportion to the dilution brought about by the added solution. The conditions favourable to the spontaneous biological reduction of acidity are: warm

storage, omission or minimisation of sulphuring, and frequent rousing of the yeast after the main fermentation. Reduction of acidity is impeded by the presence of a high proportion of tartaric acid, and therefore de-acidification with calcium carbonate before fermentation or re-fermentation promotes a rapid biological destruction of acidity. De-acidification with pure, precipitated calcium carbonate, in the early months or autumn of the year after the vintage, followed by re-fermentation, was found to give excellent results, but de-acidification of unfermented musts proved detrimental to the character of the wines. De-acidification and sugaring of young wines should only be carried out when they have been transferred to casks free from tartar.—J. H. L.

Wine; Balance of the specific gravity of —. W. J. Baragiola and O. Schuppli. Z. Unters. Nahr. Genussm., 1920, 39, 313—335.

THE sp. gr. of an aqueous solution of the total solids of a wine was found to be 1.0072, as calculated from the sum of the sp. grs. of 25 separate constituents, whilst direct determination of the sp. gr. gave 1.0084. The difference, 0.0012, between the calculated and found sp. gr. would correspond with about 3 g. per l. of total solids consisting of unknown or undetermined constituents.—W. P. S.

Jerusalem artichokes; Production of alcohol from —. M. Rüdiger. Z. Spiritusind., 1920, 43, 203.

LABORATORY experiments indicated that a fair yield of alcohol could be obtained from Jerusalem artichokes in small distilleries. Tubers which had remained in the ground until the new year, and had thus deteriorated, gave a yield of 6.4 l. of alcohol per 100 kg. by fermentation of a mash of the raw pulped material without preliminary hydrolysis. By heating the mash for an hour at 55° C. before fermentation the yield of alcohol was increased by 0.4 l., but heating at 75° or 100° C. reduced the yield. Higher yields were obtained by heating with acid, but this would not be economical for small distilleries. The spirit obtained, carefully re-distilled once, was more palatable than spirit from beets.—J. H. L.

PATENTS.

Glycerol; Manufacture of — from sugar. Verein. Chemische Werke A.-G. E.P. (A) 138,099, 20.1.20, and (B) 138,329, 21.1.20. Conv., (A) 12.4.15, (B) 22.4.16.

(A) COMMERCIAL sucrose, dextrose, levulose or invert sugar is fermented by yeast in presence of one or more organic or inorganic substances of alkaline reaction, e.g., disodium phosphate, sodium or ammonium carbonate, or sodium bicarbonate. Catalysts such as manganese or iron sulphate may also be added. (B) The yeast may be employed for successive fermentations if after each alkaline fermentation, which is preferably conducted in presence of sodium sulphite together with a small quantity of a hydrosulphite or sulphonylate, the yeast is regenerated by a purifying fermentation in presence of dilute acid. The yeast thus treated produces a higher yield of glycerol in each successive alkaline fermentation, and it also yields a surplus which can be used for baking or fodder. (Cf. Connstein and Lüdecke, J., 1919, 691 A).—J. H. L.

XIXA. FOODS.

Flour; Pentosans as a basis for determining the grade of —. J. Gerum. Z. Unters. Nahr. Genussm., 1920, 39, 65—69.

THE pentosan content of a flour affords but little evidence as regards the proportion of the wheat grain present, since the amount of pentosans contained in different grades of flour varies only within narrow limits; a "94%" flour yielded 8.77%, and an "82%" flour 7.47% of phloroglucide. Better information is obtained from the starch and ash content of the flour.—W. P. S.

Wheat flour; Detection and determination of — in mixtures with rye and barley flour. J. Abel. Z. Unters. Nahr. Genussm., 1920, 39, 44—47.

RYE flour gives no gluten, and in mixtures with wheat flour it prevents the recovery of the calculated amount of gluten from the latter; mixtures containing more than 60% of rye flour give no gluten at all. Thus mixtures of wheat and rye flours containing 0, 10, 20, 30, 40, 50, and 60% of the latter gave respectively 9.0, 8.1, 7.2, 6.0, 4.5, 2.8, and 0.6% of dry gluten. Mixtures of wheat and barley flours containing respectively 0, 10, 80% of the latter gave 9.0, 8.9, 9.2, 9.1, 9.0, 8.3, 6.2, 3.5, and 0.1% of dry gluten. The method is applicable also to doughs which have been mixed with yeast for a day or even longer.—J. H. L.

Milk; Detection of added water in — by means of the refractometer. Utz. Milchw. Zentr., 1920, 49, 137—143.

THE refractometer value of milk serum affords more trustworthy evidence of the presence of added water than does the sp. gr.; the lowest value for genuine milk is 51.0 scale degrees. The milk serum is best prepared by the use of the mercury chloride reagent (Ambühl and Weiss; J., 1920, 464 A).

—W. P. S.

Milk; Acidity of ropy —. K. Freear and E. C. V. Venn. Biochem. J., 1920, 14, 422—431.

FROM two samples of ropy milk organisms were isolated which were either identical with or closely related to *Streptococcus Hollandicus*. When these were inoculated into milk they produced ropiness associated with a minimum acidity of 0.43% lactic acid, and the ropiness continued for varying periods of time accompanied by an acidity which, except on one occasion, never rose above 1%. In every case the ropiness diminished, and after sufficient time finally disappeared. From electrometric determinations it appeared that ropiness was found in milk with a pH range of 5.82 to 4.10. With diminishing ropiness no appreciable alteration in the pH value could be detected.—W. G.

Milk, blood, and other nitrogenous substances; Improvement and treatment of —. E. F. W. Rasch. Milchw. Zentr., 1920, 49, 61—67, 77—79.

TREATMENT of the milk, blood, etc., with bases (soda, potash, lime, ammonia) or basic salts is advocated in order to neutralise the acidity and to form albuminates etc.; such treated milk or blood is suitable for drying to a powder and for other purposes.—W. P. S.

Vitamine; Quantitative method for the determination of —. R. J. Williams. J. Biol. Chem., 1920, 42, 259—265.

A KNOWN amount of the solution to be tested is added to 100 c.c. of a stock culture solution containing both asparagine and ammonium sulphate, and the mixture is made up to 110 c.c. and sterilised. 1 c.c. of a freshly-prepared suspension of yeast containing 0.3 g. of fresh yeast per l. is added and the whole is incubated for 18 hrs. A little formalde-

hyde is added to stop the growth, any growth of wild yeast on the surface is skimmed off with a copper gauze scoop, and the yeast proper is collected in a Gooch crucible, washed with water and alcohol, dried at 103° C. for 2 hrs. and weighed. The weight of yeast produced minus that produced in a control is proportional to the amount of vitamin present. The results are expressed as the "vitamine number" of the material, which is the number of mg. of yeast produced by the addition of 1 g. of the material.—W. G.

Vitamine studies. V. Antiscorbutic properties of raw beef. R. A. Dutcher, E. M. Pierson, and A. Biester. *J. Biol. Chem.*, 1920, 42, 301—310.

The addition of water extracts of raw lean beef to a basal ration deficient in antiscorbutic ingredients had no effect on the time of onset of scurvy or the length of life of guinea-pigs. The beef extract contained no deleterious ingredients, since on the further addition of orange juice to the diet there was no scurvy and the animals were in excellent condition.—W. G.

Antiscorbutic property of vegetables. II. Experimental study of raw and dried potatoes. M. H. Givens and H. B. McClugage. *J. Biol. Chem.*, 1920, 42, 491—515.

Ten grams of raw white potato per day was sufficient to protect guinea-pigs against scurvy for the duration of the experiment (129 days). There is no appreciable reduction of the antiscorbutic potency of the potato by boiling it in water for 15 mins., but if the cooking is prolonged to 1 hr. the material can no longer ward off scurvy. Various methods of drying potatoes were tried, but all caused a reduction in the antiscorbutic factor, which was still further reduced by boiling the product with water for 15 mins. Potatoes baked at 204° C. and then dried at 35°—40° C. gave the most satisfactory results, in that 2.5 g. of material daily afforded the guinea-pigs protection against scurvy.—W. G.

Vitamine; Occurrence of water-soluble — in some common fruits. T. B. Osborne, L. B. Mendel, and A. J. Wakeman. *J. Biol. Chem.*, 1920, 42, 465—489.

The fresh juices of the edible parts of the orange, lemon, and grape-fruit contain water-soluble B vitamin, being about equivalent in this respect volume for volume with cow's milk. Grape juice contains less of this vitamin. These juices may be suitably dehydrated on starch without losing their efficiency. The edible portions of apples and pears furnish some water-soluble B, but from a comparative standpoint they cannot be regarded as rich in this factor. Prunes are somewhat richer than apples and pears. From preliminary experiments it is doubtful whether lemon or grape-fruit juice contains more than traces, if any, of the fat-soluble vitamin, which, however, appears to be present in orange juice.—W. G.

Fat-soluble growth-promoting substance in lard and cottonseed oil. A. L. Daniels and R. Loughlin. *J. Biol. Chem.*, 1920, 42, 359—362.

Born lard and cottonseed oil apparently contain appreciable amounts of the fat-soluble growth-promoting substance.—W. G.

Fat-soluble factor of cabbage and carrot; Extraction of the — by solvents. S. S. Zilva. *Biochem. J.*, 1920, 14, 494—501.

Alcohol extracts the fat-soluble factor from both cabbage and carrots. In addition, such an extract from carrots contains the antineuritic and, to a lesser extent, the antiscorbutic factors. An amount of such extract equivalent to 10—12 g. of fresh carrots given daily is sufficient to promote normal

growth in rats subsisting on a diet lacking the fat-soluble factor. An ethereal extract of the alcoholic extract equivalent to 25 g. of fresh carrots promotes recovery and renews growth in rats declining in weight owing to a deficiency in fat-soluble factor.—W. G.

Apples; Odeorous constituents of —. Emanation of acetaldehyde from the ripe fruit. F. B. Power and V. K. Chesnut. *J. Amer. Chem. Soc.*, 1920, 42, 1509—1526.

The odorous constituents from the parings of different varieties of apples consist essentially of the amyl esters of formic, acetic, and caproic acids, with a very small amount of the caprylic ester. In addition there is a considerable proportion of acetaldehyde and probably some free acids. The aqueous distillate from fresh parings contains exceedingly small amounts of methyl and ethyl alcohols and furfural, the latter probably being a product of some chemical change during distillation. There is no evidence of the presence of amyl valerate. Acetaldehyde is present in the exhalations of ripe apples.—W. G.

Lupins; Loss of nutritive matters and alkaloid in the treatment of — by Löhnert's method for removing bitter substances and by the method of cold aqueous extraction. W. Dietrich and H. Jankon. *Woch. Brau.*, 1920, 37, 203—205, 211—212.

EXTRACTION of seeds of the yellow lupin in a continuous current of cold water for 72 hrs. removed only 26% of the alkaloid originally present. This treatment is therefore useless. Löhnert's method was carried out as follows:—500 g. of the seeds, without previous steeping, was boiled with 2 l. of water for 2 hrs.; the water was then replaced by 1 l. of fresh cold water, which was renewed twice within the 3 days following. This treatment removed 84% of the alkaloid originally present. Löhnert's process, like Kellner's, yields a satisfactory fodder rich in protein. Since neither of these processes, however, removes the alkaloid entirely, horses should not be given more than 1 kg. (dry substance) of the treated lupins per head per day, as they are very sensitive to alkaloids.—J. H. L.

Cocoa; Process of roasting — [by indirect heating], and apparatus for the purpose. L. A. Lévy. E.P. 148,082, 20.10.19.

XIXB.—WATER PURIFICATION; SANITATION.

Toxicity of organic compounds to wireworms; Influence of chemical constitution on the —. F. Tattersfield and A. W. R. Roberts. *J. Agric. Sci.*, 1920, 10, 199—232.

THE substances were tested in the form of vapour diluted with air. Aromatic hydrocarbons and their halides are, on the whole, more toxic than aliphatic hydrocarbons and their halides. When introduced singly into the benzene ring the substituents which influence toxicity most may be arranged in descending order of effectiveness as methylamino, dimethylamino, hydroxy, nitro, amino, iodine, bromine, chlorine, methyl groups. This order is, however, modified if another group is present. Chlorine and hydroxy groups together give rise to highly poisonous substances. The association of chlorine and nitro groups together in chloropicrin gives rise to one of the most toxic substances tested. Compounds with irritating vapours usually have high toxic values, e.g., allyl isothiocyanate, chloropicrin, benzyl chloride, but their toxic values are not closely correlated with their vapour pressures or rates of evaporation. In the case of compounds of the same chemical type there is a fairly close relationship between toxicity and vapour pressure, rate of evaporation, and volatility. In a series of such compounds decrease in vapour pressure and in volatility is associated with increased toxicity. Chemically inert compounds boiling above 170° C. are generally uncertain in their poisonous effect on wireworms. Nearly all organic compounds boiling above 215° C. are uncertain in their action, while those boiling above 245° C. are non-toxic, though these limits depend to some extent on the resistance of the insect, the length of exposure, and the temperature at which the experiment is carried out.—W. G.

Sand-filters. N. M. Barron. E.P. 146,577, 3.4.19.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Glycerophosphates; Detection of inorganic phosphate in —. J. L. Lizius. *Pharm. J.*, 1920, 105, 100—101.

WHEN 0.1 g. of a glycerophosphate is treated with 10 c.c. of dilute nitric acid and 10 c.c. of 10% ammonium molybdate solution, the development of a turbidity indicates the presence 0.1%, or more, of inorganic phosphate. A more sensitive reagent (Scott and Plimmer, *J. Physiol.*, 1906, 35, 120) is prepared by adding 80 c.c. of 10% ammonium molybdate solution to 12 c.c. of hydrochloric acid (sp. gr. 1.16) and then introducing, successively, 20 g. of ammonium chloride and 10 c.c. of saturated potassium persulphate solution. Five c.c. of this reagent is mixed with 0.1 g. of the glycerophosphate; a turbidity forms within a few mins. if as little as 0.001% of inorganic phosphate is present. The U.S.P. test is untrustworthy, possibly due to the fact that an excess of molybdate reagent is not used.—W. P. S.

Acetylsalicylic acid; Determination of free acetic acid in —. A. N. Smith. *Pharm. J.*, 1920, 105, 90—94.

ONE gram of the sample is spread in a thin layer

on the surface of a piece of "robe muslin" tied over the top of a funnel of 3.5 in. diam.; the stem of the funnel fits through a hole in a ground-glass plate and the whole is covered with a bell-jar. A tube from the top of the bell-jar is connected with a vessel containing water (previously boiled), and this in turn with a water-pump by which a current of pure air is aspirated through the apparatus. The air enters through the stem of the funnel, passes through the layer of acetylsalicylic acid and then bubbles through the water; the acetic acid is absorbed and is determined by titration. Free salicylic acid does not volatilise under these conditions.—W. P. S.

Diazo compounds; New catalytic elements for the transformation of —. A. Korczynski, W. Mrozinski and W. Vielau. *Comptes rend.*, 1920, 171, 182—184.

NICKEL and cobalt salts may be used equally well in place of copper salts for certain of the changes brought about by the Sandmeyer reaction. Thus nickel salts may be used for the preparation of nitriles, and cobalt salts for the preparation of thiocyanates from the corresponding diazonium salts. Zinc and iron salts showed no sign of any catalytic action for these changes. (*Cf.* J.C.S., Sept.)—W. G.

Nitriles; Catalytic hydration of —. A. Mailhe. *Comptes rend.*, 1920, 171, 245—247.

NITRILES may be converted into the corresponding acids by passing their vapours along with steam over thoria at 420° C.—W. G.

Catalytic oxidation of alcohols by the use of metallic oxides and of finely divided metals. J. B. Senderens. *Ann. Chim.*, 1920, 13, 266—283.

NONE of the oxides tried (nickel, copper, vanadium, molybdenum, and zinc oxides) was satisfactory as catalyst in the oxidation of alcohols to aldehydes or acids. Of the metals tried in the form of turnings or powder, silver was the only one which gave at all satisfactory results.—W. G.

Formaldehyde; Degree of alkalinity necessary for the phloroglucinol test for —. P. J. Hanzlik. *J. Biol. Chem.*, 1920, 42, 411—413.

THE minimum alkalinity necessary for a positive reaction in the phloroglucinol test for formaldehyde is equivalent to $pH=12.13$, or $N/100$ sodium hydroxide. The optimum alkalinity is $pH=13.0$ or $N/10$.—W. G.

Cineol; Determination of — in eucalyptus oils. T. T. Cocking. *Pharm. J.*, 1920, 105, 81—82.

THREE grams of the eucalyptus oil is mixed with 2.1 g. of o-cresol and the solidifying pt. of the mixture is determined. Reference to a graph, constructed from the results obtained with mixtures containing known amounts of cineol, gives the percentage of cineol corresponding with the solidif. pt. found.—W. P. S.

"Cresineol," a compound of cineol and o-cresol. T. T. Cocking. *Pharm. J.*, 1920, 105, 81.

CINEOL and o-cresol combine in molecular proportions to form a crystalline product termed "cresineol." m. p. 55.2° C., sp. gr. at 60°/60° C. 0.9661, $n_D^{20}=1.4846$; this substance is soluble in organic solvents generally and is decomposed into its constituents by alkali hydroxides.—W. P. S.

See also pages (A) 596, *Mercuric oxycyanide* (Jones), *Action of finely-divided gases* (Zenghelis); 611, *Fluorometry* (Desha), *Organic acids etc.* (Foreman), *Oxalic acid* (Ban), *Methyl alcohol* (Gettler).

PATENTS.

Camphor; Process of oxidising iso-borneol to —. R. L. Andreau, Assr. to E. L. du Pont de Nemours and Co. U.S.P. 1,347,071, 20.7.20. Appl., 12.11.17.

ISOBORNEOL is oxidised to camphor by means of mixed nitric and sulphuric acids.—A. de W.

Tuberculosis, leprosy, and other diseases; Substance for treatment of —. R. S. Paschall. E.P. 116,078, 5.4.18. Conv., 17.11.17.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENT.

Colour photography. Natural Colour Pictures Co., Assees. of W. F. Fox. E.P. 143,180, 14.10.19. Conv., 12.5.19.

PRINTS are made in register from two complementary colour-sensation negatives on opposite sides respectively of a transparent base sensitised on both sides. Both prints are toned to a colour corresponding to that through which one of the negatives was taken, then the positive printed through that negative is toned in a solution which will change the tone already obtained to its complementary. For example, if a red and a green filter have been used in taking the negatives, the first toning bath may be a uranium ferri cyanide solution and the second toning bath, applied to the positive from the "red" negative, may be a ferric ammonium oxalate solution. In the second toning operation, the solution may be applied to one side by a suitable rolling or brushing device, or the side not required to be toned may be protected by a waterproof coating.—B. V. S.

XXIII.—ANALYSIS.

Melting point curves; Estimation of impurities by means of —. W. P. White. J. Phys. Chem., 1920, 24, 393—416.

FREEZING points are more accurately determined by immersing the thermometer in the substance than by the capillary tube method. If in addition the form of the melting point curve is observed, an indication of the amount of impurity present is obtained, which is independent of all previous knowledge or uncertainty as to the melting point of the pure substance and even of the absolute accuracy of the thermometer. Small tubes diminish local temperature differences and are often a superior substitute for a stirring rod. A small thermocouple may also with advantage be used instead of a thermometer.—J. F. S.

Fluoremetry. Quantitative analysis by comparative fluorescence. L. J. Desha. J. Amer. Chem. Soc., 1920, 42, 1350—1363.

A NEW method of micro-analysis, of the same order of sensitiveness as colorimetry and nephelometry, is described. This should prove generally applicable to the estimation of minute quantities of substances, which are either fluorescent themselves or may be rendered so by the addition of a suitable reagent. Ultraviolet rays from a quartz mercury lamp, from which most of the visible radiations

have been removed by means of a colour filter, are used to excite fluorescence in solutions of such substances contained in the comparison tubes of the Kober nephelometer. The intensity of the fluorescent light thus produced, as observed in the eyepiece of the instrument, is equalised in the usual manner by altering the heights of the exposed columns. For sufficiently dilute solutions the curves obtained by plotting the scale readings against concentrations are quite regular. Calibration curves for solutions containing 0.5—2.0 mg. per l. of quinine sulphate in N/1 sulphuric acid and for solutions of 2—4 mg. per l. of Anilino Iodococin in N/10 alkali are given.—J. F. S.

Methyl orange as indicator. V. Macri. Boll. Chim. Farm., 1920, 59, 193—196.

CHLORINE in either acid or alkaline solution destroys methyl orange and bromine acts similarly, whereas iodine is without effect. Hydrosulphurous acid destroys methyl orange, but not in presence of formaldehyde; the destruction caused by certain alkali sulphides depends on the presence of accidental impurities. Of oxygen-yielding compounds, hydrogen peroxide is without action on methyl orange, but ozone readily destroys it. In the alkalimetric titration of percarbonate the indicator is destroyed immediately any free alkali carbonate is completely neutralised and the percarbonate begins to undergo decomposition. The indicator is readily destroyed by nitrous acid but serves in titrating cyanic, thiocyanic, and carbonylferrocyanic acids; with hydrocyanic acid it is insensitive and with ferrocyanic acid uncertain. Certain bases, notably ferrous and manganous oxides, destroy it, the yellow colour persisting when a solution of a ferrous or manganous salt, precipitated by addition of alkali, is re-acidified. This phenomenon, due to the reducing action of the two hydroxides, is not observed if hydrogen peroxide is added prior to the alkali. Both the free and the combined acid in solutions of ferrous and manganous salts may hence be determined by titration. With ferrous salts it is necessary to allow for the free acid entering into combination in accordance with the equation: $2\text{FeSO}_4 + n\text{H}_2\text{SO}_4 + \text{O} = \text{Fe}_2(\text{SO}_4)_3 + (n-1)\text{H}_2\text{SO}_4 + \text{H}_2\text{O}$; with manganous salts, however, manganic salts are not formed under ordinary conditions. Stannous chloride also destroys the indicator, but only in acid solution, and here, too, when hydrogen peroxide is used, the free acid combining to form the stannic salt must be taken into account. Copper salts behave like those of tin, and cobalt salts like those of iron and manganese. The mercurous oxide precipitated from the nitrate by addition of alkali does not destroy the coloration but carries down the colouring matter with it. In the titration of commercial and fuming sulphuric acid methyl orange is sometimes destroyed owing to the impurities present, and the same is observed with alkali hydroxides, even with those sold as pure. Ethyl alcohol is markedly alkaline towards methyl orange, whereas methyl alcohol is without effect.—T. H. P.

Methyl red; Preparation of —. L. Desvergnès. Ann. Chim. Analyt., 1920, 2, 209—210.

A MIXTURE of anthranilic acid, 137, water, 1000, crushed ice, 300 g., and hydrochloric acid (sp. gr. 1.18), 222 c.c., is stirred and kept below 5° C., while a mixture of sodium nitrite, 59, and water, 150 g., is added. The whole is stirred for a further 20 mins. and then added to a mixture of dimethylaniline, 121, water, 200 g., and hydrochloric acid (sp. gr. 1.15), 90 c.c. After a few mins., a mixture of fused sodium acetate, 165, and water, 500 g., is added. The purple red crystals which separate when the mixture is set aside for some hrs. are collected, washed with cold water, dried at 50° C., and recrystallised from alcohol. The yield of the crude product is about 43% of the theoretical amount calculated on the anthranilic acid.—W. P. S.

Sodium thiosulphate, arsenious acid, potassium bromate, potassium iodate, etc. solutions; Standardisation of — by means of standard sulphuric acid solution. L. Bertiaux. *Ann. Chim. Analyt.*, 1920, 2, 207—208.

THE equivalent quantity of iodine liberated from a mixture of potassium iodate and iodide by a definite volume of standard sulphuric acid solution may be used for the standardisation of thiosulphate or arsenious acid solutions. The latter solutions then serve for the standardisation of bromate or iodate solutions.—W. P. S.

Titration with the hydrogen electrode. W. D. Treadwell and L. Weiss. *Helv. Chim. Acta*, 1920, 3, 433—446.

A HYDROGEN electrode is described which is highly stable and readily renewed, and serves for the titration of both strong and weak acids.—T. H. P.

Potassium; Determination of — and its separation from sodium by means of sodium cobaltinitrite. P. Wenger and C. Hémen. *Ann. Chim. Analyt.*, 1920, 2, 198—199.

POTASSIUM cobaltinitrite precipitate obtained in the usual way has the composition $K_2NaCo(NO_2)_6$, and the author recommends a determination of the cobalt as a measure of the potassium present. The precipitate is dissolved in hydrochloric acid, the solution treated with sodium hydroxide, the precipitated cobalt hydroxide collected, reduced to metallic cobalt, and weighed. Alternatively, the cobalt may be determined electrolytically in the hydrochloric or sulphuric acid solution of the precipitate.—W. P. S.

Lead; Determination of — in acid solution. N. Evers. *Pharm. J.*, 1920, 105, 85—86.

THE sulphide colorations obtained in the determination of small quantities of lead are not comparable unless the solutions have the same hydrogen ion concentration; the author recommends neutralisation of the test and comparison solutions before the addition of hydrogen sulphide. Bromophenol-blue is used as indicator. Iron does not give a coloration under these conditions, and the interference of copper may be prevented by the addition of cyanide. If both iron and copper are present, the original solution should be treated with alum and ammonia, the aluminium hydroxide precipitate (this also contains the lead whilst the copper remains in solution) collected, dissolved in dilute acid, and this solution used for the determination of the lead.—W. P. S.

Manganese; Estimation of — in biological material, together with data on the manganese content of human blood and tissues. C. K. Reiman and A. S. Minot. *J. Biol. Chem.*, 1920, 42, 329—345.

FOR the preliminary conversion of manganese in the blood or tissue into manganese sulphate Bertrand's method (*J.*, 1911, 650) of fusion with potassium bisulphate is modified, the fusion being conducted in quartz beakers at 500°—600° C. The beakers are liable to contain manganese and must first be tested by a preliminary fusion. For the conversion of the manganese sulphate into potassium permanganate, treatment with potassium persulphate is recommended, Bertrand's modification (*loc. cit.*) of Marshall's method (*Chem. News*, 1901, 83, 76) being further modified.—W. G.

Manganese; The use of phenolphthalein and diphenylamine in the persulphate method for the determination of —. D. H. Wester. *Rec. Trav. Chim.*, 1920, 39, 600—602. (*Cf. J.*, 1920, 469 A.)

THE author was unable to obtain accurate results by the use of phenolphthalein in alkaline solution

as a comparison liquid, or by the use of diphenylamine for intensifying the colour as recommended by Tillmanns and Mildner (*J.*, 1914, 709).—W. G.

Barium sulphate; Rapid identification of the two ionic elements of —. G. Deniges. *Bull. Soc. Chim.*, 1920, 27, 560—564.

A FULLER account of work already published (*cf. J.*, 1920, 469 A).—W. G.

Diphenylamine - sulphuric acid reagent [for nitrates]; Preparation of —. F. Haun. *Z. Unters. Nahr. Genussm.*, 1920, 39, 355—356.

SULPHURIC acid which yields a reaction for nitric acid with the brucine test is unsuitable for the preparation of diphenylamine reagent. Occasionally a blue coloration, which develops in a reagent made with sulphuric acid free from nitric acid, may be due to the presence of traces of ferric salts; if the acid is heated to boiling the ferric salts are reduced and no longer interfere. By adding a small quantity of permanganate to the acid before it is heated, the reduction of the ferric salts may be followed, since the permanganate is reduced at the same time and a colourless acid results. The presence of manganese in the reagent does not interfere and in some cases accelerates the reaction between the reagent and nitrates.—W. P. S.

Hydrocyanic acid; Determination of —. R. L. Morris. *Pharm. J.*, 1920, 105, 83—85.

IN applying Liebig's method to the determination of free hydrocyanic acid, the latter must be neutralised previously and only a slight excess of alkali must be present. Borax solution may be used in place of alkali hydroxide for the neutralisation (Guerin, *J.*, 1905, 1258), and an excess of borax does not interfere. The iodometric method proposed by Fordos and Gelis (*cf. Guerin, loc. cit.*) tends to give low results. In the B.P. (1914) method, based on Deniges' modification of Liebig's process (*cf. J.*, 1894, 664), to obtain accurate results it appears to be necessary to add about four times the prescribed quantity of potassium iodide.—W. P. S.

Recording [gas] calorimeters; Differential air thermometers and —. H. A. Madsen and A. Herber. *Gas J.*, 1920, 151, 338—339.

THE principle of the differential air thermometer is applied to the construction of a recording gas calorimeter. The long tube connecting the two bulbs of the differential air thermometer is bent into a ring or spiral which is balanced on friction wheels. The lower part of the ring is filled with mercury. One bulb is exposed to the hot products of combustion arising from a flame due to the combustion of gas at a controlled rate, the air supply for combustion and the supply of air to be heated being separated. The latter supply is automatically controlled by means of a damper. A pen is affixed to a lever attached to the horizontal portion of the tube connecting the bulbs, and serves, after calibration of the instrument, to record the calorific value of the gas on a drum.—J. S. G. T.

Gas analysis apparatus accurate to 0.001% mainly designed for respiratory exchange work. A. Krogh. *Biochem. J.*, 1920, 14, 267—281.

TWO improvements are introduced into the usual apparatus. Three separate gas burettes are used, the first for moving the air to and from the absorption pipettes, the second for measuring the air after the absorption of carbon dioxide, and the third for measuring the air after the absorption of oxygen. The mercury is raised and lowered in the burettes by means of air pressure.—W. G.

Carbon dioxide in flue gases etc.; Continuous electrolytic determination of — and automatic regulation of the draught in accordance with the analysis. K. von Haken. *Z. angew. Chem.*, 1920, 33, 188.

The gases are passed through an ordinary purifying apparatus, and enter the electrolytic apparatus through a valve controlled by a sensitive differential manometer charged with two immiscible liquids of different sp. gr., and regulated by a float. They are then mixed with a standard solution of sodium hydroxide to remove the carbon dioxide, and passed through a second differential manometer, which regulates the pressure in the mixing vessel in the reverse direction. The solution of sodium bicarbonate produced flows into the electrolytic vessel which has a regulated overflow, and is electrolysed with an alternating current, the current of the secondary coil being conducted through a milli-ampere-meter or similar device, which shows directly the amount of CO_2 in the gas. The method is based on the difference in the conductivity of the original sodium hydroxide solution and of that containing the dissociated salts and acid salts after the absorption of the CO_2 , and is sensitive to fractions of 0.1%. The draught is regulated by an automatic shutter, the aperture of which varies with the variation in the amount of CO_2 .—C. A. M.

Organic substances; Incineration of — prior to analysis for the mineral elements which they contain; application to the analysis of blood. A. Desgrez and J. Meunier. *Comptes rend.*, 1920, 171, 179—182.

For the preparation from organic material of an ash suitable for subsequent analysis it is advisable to conduct the incineration in two stages. The dry material is first ignited and allowed to burn at as low a temperature as possible. In this way a carbonised material is obtained which on further incineration readily becomes incandescent and burns to a white ash. If excess of alkali salts is present these should be extracted with water before the final incineration. By means of this method the presence of copper, manganese, and lithium in blood was detected.—W. G.

Capillary active and inactive modifications of the higher homologues of the fatty acid series and their relation to titration with capillary active substances as indicators. W. Windisch and W. Dietrich. *Woch. Brau.*, 1920, 37, 215—217, 225—228. (*Cf. J.*, 1920, 128A.)

UNDECYLIC, nonyllic, and capric acids may exist in capillary inactive as well as capillary active forms. In a state of molecular dispersion, and in a relatively coarse suspensoid state, the acids are inactive, but in an intermediate colloidal state they are active. Solutions of the pure fatty acids might be used as indicators in place of their sodium salts, but the latter are preferable in most cases, because in solution the free fatty acids become inactive in the course of a few days, i.e., the surface tension of their solutions gradually approximates to that of pure water, probably owing to the colloidal particles increasing in size beyond the optimum.—J. H. L.

Amino-acids, organic acids, and organic bases; Rapid volumetric methods for the estimation of —. F. W. Foreman. *Biochem. J.*, 1920, 14, 451—473.

The method, which is applicable to the estimation of organic acids, and amino-acids except arginine, is as follows:—(1) 5—10 c.c. of the aqueous solution is titrated with $N/10$ -aqueous sodium hydroxide. (2) 10 vols. of 97% alcohol is added to 5—10 c.c. of the aqueous solution and the mixture is titrated with $N/10$ -alcoholic potassium hydroxide. (3) To the liquid from titration (2) 12.5 c.c. of neutral 13% aqueous formaldehyde is added for every 50 c.c.

of alcohol present and the titration is continued to the same end-point. Phenolphthalein is used in all cases as the indicator. Titration (1) gives useful information when dibasic amino-acids are present. Titration (2) gives the correct estimation of a number of amino-acids. In titration (3) the carboxyl groups of all the amino-acids in an amino-acid mixture, except that of arginine, are estimated. The method is based on the fact that ammonia, primary, secondary, and tertiary amines and basic methylene derivatives of secondary amines do not form ionisable compounds with phenolphthalein in aqueous-alcoholic solution providing the concentration of alcohol is above 80%, and also that, under similar conditions, the amino- or imino-groups of certain amino-acids show no basicity to phenolphthalein. For the estimation of volatile bases and amino-acids in "alcoholic extracts" (Foreman and Graham-Smith, *J. Hyg.*, 1917, 16, 144) to an aliquot portion of the extract the amount of alcoholic alkali necessary for neutralisation as determined by titration (3) is added and the mixture is distilled with steam free from carbon dioxide for about 5 mins., the distillate being collected in standard acid. The excess acid is titrated, using alizarin as indicator, and thus a measure of the volatile bases is obtained. The residual liquid in the distillation flask is now free from alcohol and, owing to hydrolysis in the water of the alkali salts of the amino-acids, is alkaline. It is titrated with $N/10$ -acid and thus a value is obtained for the amino-acids present in the original "alcoholic extract." (*Cf. J.C.S.*, Sept.)—W. G.

Arginine; Modification of the Van Slyke method for determining —. A. E. Koehler. *J. Biol. Chem.*, 1920, 42, 267—268.

VAN SLYKE's method (*J.*, 1911, 1135) is modified by drawing a slow current of air through the liquid during the whole of the digestion with alkali, the apparatus for absorbing the ammonia being a simple gas wash-bottle.—W. G.

Oxalic acid; Determination of —. III. A. Bau. *Woch. Brau.*, 1920, 37, 201—203, 209—211, 217—219. (*Cf. J.*, 1918, 524 A; 1920, 349 A.)

THE extraction of materials with water or dilute hydrochloric acid, for the determination of oxalic acid, should be carried out in an atmosphere of carbon dioxide to prevent the decomposing action of iron salts in presence of air. A further reason for this procedure is furnished by Stachelin's discovery of the wide distribution, in vegetable materials, of an oxydase capable of decomposing oxalic acid in presence of air (*Biochem. Zeits.*, 1919, 96, 1). Liquids of yellow colour, such as beer or urine, containing oxalic acid, may be exposed to daylight for months without any destruction of oxalic acid occurring. For the preservation of standard oxalic acid solutions Junk's method (*J.*, 1919, 481 A) is probably the best, but the solutions should be kept in yellowish-brown bottles and standardised every three months.—J. H. L.

Methyl alcohol; Critical study of methods for the detection of —. A. O. Gettler. *J. Biol. Chem.*, 1920, 42, 311—328.

A CRITICAL study of 58 tests for the detection of methyl alcohol, 46 being based on the oxidation of the alcohol to formaldehyde and the subsequent detection of this compound, and twelve applied directly to the alcohol after suitable isolation. Of the first series the author recommends five colorimetric tests which can be used to detect one part in 200,000, and two tests in which crystalline products are obtained, these being less sensitive but used for confirmation. The second group of tests require considerably more alcohol and only two are recommended. Full details of typical pro-

cedures for the detection of methyl alcohol in liquors and in tissues are given, and there is a very full bibliography. (*Cf.* J.C.S., Sept.)—W. G.

Ion concentration in ultra filtrates and other protein-free solutions; Determination of the —.
R. Brinkman and E. van Dam. *Proc. K. Akad. Wetensch.* Amsterdam, 1920, 22, 762—771.

THE method depends on the addition of an ion which forms a sparingly soluble salt with the ion, the concentration of which is to be measured. The appearance of a milkiness denotes when the limit of solubility of the sparingly soluble salt is passed. The method gives results correct to 2—3 mg. of calcium per litre.—J. C. D.

 25,206 (1919). Denoel. Decantation apparatus. (149,551.) Aug. 25.
 27,427 (1919). Ehrhart. Surface condensers. (131,852.) Aug. 25.
 32,370 (1919). Smith and Stephenson. Heat-exchange apparatus. (149,882.) Sept. 1.
 13,058 (1920). Chantaine. Recuperators or regenerators for furnaces. (143,244.) Aug. 25.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Angold and Railing. Electric arc lamps. 23,479. Aug. 11.
 Bamber and Parker. Means for supplying air and steam to producer-gas plants. 23,648. Aug. 12.
 Barrele. Manufacture of coke for metallurgical purposes. 24,270. Aug. 20.
 Barrett Co. Manufacture of coke. 23,455. Aug. 10. (U.S., 10.12.19.)
 Bennett. Mechanically-operated grates for gas-producers and furnaces. 24,892. Aug. 28.
 British Thomson-Houston Co. (General Electric Co.) Electric incandescent arc devices. 24,546. Aug. 24.
 Brown. Regenerative coke-ovens. 23,545. Aug. 11.
 Charpy. Coke-oven. 23,809. Aug. 14. (France, 10.9.19.)
 Coke and Gas Ovens, Ltd., and Smee. Gas burners of coke-ovens. 23,622. Aug. 12.
 De Beaufort and Claude. Manufacture and working of luminous tubes. 24,190. Aug. 19. (France, 29.8.19.)
 Edser. Fuel. 23,825. Aug. 14.
 Farbw. vorm. Meister, Lucius, u. Brünig. 23,446. *See* XX.
 Filippo, Lely, and N. V. Philips Gloeilampen-fabrieken. Electric discharge lamps. 24,835. Aug. 27. (Holland, 27.8.19.)
 Fischer. Process for converting combustible substances into soluble organic compounds. 23,354. Aug. 9. (Germany, 10.6.19.)
 France. Coal etc. washing apparatus. 24,195. Aug. 19. (Belgium, 20.8.19.)
 France. Filament electric lamps. 24,018. Aug. 18.
 General Electric Co., and Ryde. Electric incandescent lamps. 24,660. Aug. 25.
 Heenan. 23,507. *See* XII.
 Hilger. Operating gas-producers. 23,869. Aug. 16. (Germany, 11.8.19.)
 Jackson (Sperry Gyroscopo Co.). Arc lamps. 23,552. Aug. 11.

Keillor. Combination plant for manufacture of coal gas, blue-water gas, and coal-tar or oil-gas. 23,700. Aug. 13.
 Massy. Appliances for conversion of fuel energy for heating or power. 23,672. Aug. 13.
 Morton and Morton. 24,890. *See* I.
 Noding. 24,217-9. *See* VII.
 O'Dell. 24,480. *See* III.
 Parr and Pearson. Process for desulphurising carbonaceous material. 24,432. Aug. 23.
 Roberts. Coking coal. 24,338. Aug. 21.
 Stephens (Canadian-American Finance and Trading Co.). Process for volatilising and decomposing hydrocarbons. 23,357. Aug. 9.
 Stephens (Canadian-American Finance and Trading Co.). Process for treating hydrocarbons. 23,646. Aug. 12.
 Stephens (Canadian-American Finance and Trading Co.). Process for saturating unsaturated compounds. 23,647. Aug. 12.
 Turner. Electric generator lamps. 24,607. Aug. 25.
 Wells. Gas producers. 23,992. Aug. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

6139 (1914). British Thomson-Houston Co. (General Electric Co.). Filaments for incandescent electric lamps and methods of making the same. Sept. 1.
 2764 (1919). Gregory. Means for generating and storing combustion products under pressure for use in turbines and other engines. (149,367.) Aug. 25.
 11,420 (1919). Marks (U.S. Industrial Alcohol Co.). Process of producing liquid fuel and product thereof. (149,398.) Aug. 25.
 11,773 (1919). Doherty. Process and apparatus for producing water-gas and for carbonising coal. (132,488.) Aug. 25.
 12,175 (1919). Dressler Tunnel Ovens, Ltd., and Dressler. Treatment of coal and other materials capable of being distilled, vaporised, or decomposed by heat. (149,086.) Aug. 18.
 12,317 and 26,640 (1919). Brown and Pickston. *See* XXIII.
 12,393 (1919). Markle. Fuel and process of forming the same. (126,972.) Sept. 1.
 12,396 (1919). Bentley and Appleby. Gas-producers. (149,759.) Sept. 1.
 12,585 (1919). Wells. Process and apparatus for carbonising wood and other carbonaceous material. (149,773.) Sept. 1.
 12,621 (1919). Armstrong. Manufacture of fuel, and apparatus therefor. (149,449.) Aug. 25.
 13,225 (1919.) Milton. Gas producers. (149,790.) Sept. 1.
 27,370 (1919). Ulmann. Process and apparatus for the treatment of peat-mass and for the production of turf or peat briquettes. (149,869.) Sept. 1.
 29,003 (1919). Pintsch A.-G. Porous charges for containers for the storage of acetylene or like explosive gases dissolved in liquids. (135,511.) Aug. 25.
 14,775 (1920). British Thomson-Houston Co. (General Electric Co.). Manufacture of incandescent electric lamps. (149,605.) Aug. 25.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Anderson and Meikle. Process of treating mineral tars other than coal tar. 23,569. Aug. 12.
 Barrett Co. 23,454. *See* XIII.
 Commin. Covering of pitch composition. 23,296. Aug. 9.
 Fischer. 23,422. *See* XIII.
 O'Dell. Hydrogenating bituminous substances. 24,480. Aug. 23.
 Schroeter, and Tetralin Ges. Hydrogenation of naphthalene. 23,530. Aug. 11.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

Carpmael (Farbenfabr. vorm. F. Bayer und Co.). Manufacture of soluble chromium lakes of azo dyes. 23,551. Aug. 11.

Cassella und Co. Manufacture of dye-stuffs. 24,877. Aug. 27. (Germany, 27.8.19.)

COMPLETE SPECIFICATION ACCEPTED.

25,916 (1919). Imray (Soc. of Chem. Ind. in Basle). Manufacture of azo-dyestuffs and intermediate products therefor. (149,553.) Aug. 25.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Bearder. Manufacture of cellulose-acetate filaments. 24,594. Aug. 25.

Billings. Fibrous product, and process for treating eucalypti barks and bass fibres for use in manufactures. 23,716. Aug. 13.

Brougham (Technochemia A.-G.). Manufacture of artificial silk etc. 24,277. Aug. 20.

Denington and Perry. 24,746. *See* XVIII.

Duvinae and Muth. 23,960. *See* VII.

Jackson (Tanners Products Co.). Manufacture of felt. 23,434. Aug. 10.

Meldia Manufacturing Co., and Melsom. Manufacture of flexible waterproof and gas-proof material. 23,364. Aug. 9.

Raitt. Isolating or extracting cellulose or paper pulp from fibrous vegetable materials. 23,864. Aug. 16.

Whittaker. Manufacture of paper. 24,266—7. Aug. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

4451 (1914). Frankel & Runge, and Colombek. Manufacture of waterproof material. Sept. 1.

18,938 (1917). Wood and Russell. Paper-making machines. (149,359.) Aug. 25.

13,226 (1919). Pilkington, and Mandleberg and Co. Proofing of fabrics. (149,791.) Sept. 1.

31,190 (1919). Gillet et Fils. Treating vegetable fibres. (136,569.) Aug. 25.

31,790 (1919). Great Northern Paper Co. Paper-making. (136,839.) Aug. 18.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Brandwood and Brandwood. Dyeing, bleaching, etc. textile fibres etc. 24,423. Aug. 23.

De Blicquy and Callebaut. Dye-vats etc. 24,823. Aug. 27.

Farbw. vorm. Meister, Lucius, und Brüning. Producing fast dyeings on cotton etc. 24,303. Aug. 20. (Germany, 30.5.14.)

Winslow. Apparatus for dyeing yarn in cop, cheese etc. form. 24,330. Aug. 21.

COMPLETE SPECIFICATION ACCEPTED.

11,958 (1919). McMyn. Application of dyestuffs containing the sulphonamide group to dyeing and printing. (149,428.) Aug. 25.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Alby United Carbide Factories, and Mitchley. Production of calcium carbide. 23,425. Aug. 10.

Amsterdamsche Superfosfaatfabriek, and Hirschel. Manufacture of phosphoric acid. 24,193. Aug. 19. (Holland, 24.6.20.)

Duvinae and Muth. Process for preparing compounds of alumina for sizing paper etc. 23,960. Aug. 17. (Germany, 18.8.19.)

Heinemann, and Hoesch & Co. Process for recovery of pure caustic alkalis from impure lyes. 23,818. Aug. 14.

Holden and Pandrich. Utilisation of nitre cake and waste liquor from the ammonia-soda process. 24,937. Aug. 28.

Kestner. 24,052. *See* I.

Macfarlane and Spink. 24,529. *See* XI.

Nöding. Methods of obtaining hydrogen. 24,247. 24,249. Aug. 20.

Nöding. Retort furnace for generation of hydrogen. 24,248. Aug. 20.

Noef. Recovery of sulphur from sulphuretted hydrogen and ammonium sulphide and gases containing such. 24,387. Aug. 23.

Norske Aktieselskab for Elektrokemisk Industri Norsk Industri-Hypotekbank. Process for production of alumina from aluminium nitrate solutions. 24,847. Aug. 27. (Norway, 19.9.19.)

Tyrer. Extraction of alumina 24,579. Aug. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

3754 (1919). Freeth and Munro. Removal of calcium and magnesium from rock salt, brine, or solutions of rock salt in water. (149,707.) Sept. 1.

12,494 (1919). Morel. Process for the manufacture of alumina. (149,769.) Sept. 1.

12,642 (1919). Freeth and Cocksedge. Manufacture of ammonium nitrate. (149,095.) Aug. 18.

12,698 (1919). Hood. Preparation of aluminium nitrate. (149,783.) Sept. 1.

12,699 (1919). Hood. Conversion of powdered aluminous materials into granular form. (149,453.) Aug. 25.

25,688 (1919). Hedstrom. Production of compounds of radium. (149,552.) Aug. 25.

VIII.—GLASS; CERAMICS.

APPLICATIONS

Atkinson, and Stein and Atkinson. Drying china clay etc. 24,250. Aug. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

17,254 (1918). Vergniaud. Apparatus for drying crucibles. (149,703.) Sept. 1.

12,025 (1919). Smith. Treatment of clays, and manufacture of articles and materials therefrom. (149,440.) Aug. 25.

30,586 (1919). Sato. Manufacture of decorative glass, porcelain, and the like. (149,567.) Aug. 25.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Berry. Manufacture of artificial stone, cement, etc. 24,469. Aug. 23.

Boyerolle. Manufacture of cement from slag. 23,277. Aug. 9. (Belgium, 7.3.19.)

Commin. 23,296. *See* III.

Imperial Trust for the Encouragement of Scientific and Industrial Research, and Schryver. Manufacture of plastic material for flooring etc. 23,640. Aug. 12.

Vaughan. Cement. 24,649. Aug. 25.

COMPLETE SPECIFICATIONS ACCEPTED.

2341 (1914). Leger. Composition for use in the construction of walls, linings, panels, roof coverings, coach bodies, or the like. Aug. 18.

12,438 (1919). Fasting. Rotary kilns for burning cement and the like. (149,764.) Sept. 1.

16,136 (1919). Steiger. Manufacture of tiles, flags, sheetings, or the like of cement and fibre. (149,120.) Aug. 18.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.**APPLICATIONS.**

- Ball. Production of powdered metals. 23,738. Aug. 13.
 Barrelle. 24,270. *See* II.
 Bengough. Coating metals with lead. 23,721. Aug. 13.
 Boveroulle. 23,277. *See* IX.
 British Thomson-Houston Co. (General Electric Co.). Arc-welding compositions. 24,261. Aug. 20.
 Brunskill. Treatment for prevention of surface corrosion in aluminium alloys. 24,035. Aug. 18.
 Chambers and Fisher. Treating iron and iron alloys. 23,745. Aug. 13.
 Chesterfield and Harden. Applying lead linings to steel etc. pipes. 24,582. Aug. 21.
 De Lavandeyra. Method of heat-treating alloys and operating heat-treating furnaces. 24,585. Aug. 24. (U.S., 3,320.)
 Gamlen. Process for reducing iron ore. 24,551. Aug. 24.
 Hale. Metal, and method of manufacturing same. 23,494. Aug. 11.
 James. Manufacture of tin, terne, etc. coated plates etc. 24,936. Aug. 28.
 Jones. Treatment of impure zinc etc. 24,886. Aug. 28.
 Krupp A.-G. Grusonwerk. Process of separating slags containing iron from coke etc. residues. 24,343. Aug. 21; and 24,471. Aug. 23. (Germany, 26.8 and 11.10.19.)
 Manchester Furnaces, Ltd., and Russell. Heat-treatment furnaces. 24,670. Aug. 25.
 Marino. 24,659. *See* XI.
 Mond (Metallbank u. Metallurgische Ges.). Process for separation of metals from alloys. 24,047. Aug. 18.
 Perkins. Treatment of complex sulphide ores. 23,487, 24,924. Aug. 16 and 28.
 Stein et Cie. Crucible smelting-furnaces. 23,987. Aug. 17.
 Wills. Alloy steel. 24,524. Aug. 21. (U.S., 9.6.17.)
 Wood and Wood. Cupolas or melting or heating furnaces. 24,102. Aug. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

- 243 (1919). Wilson. Treatment of arsenious ores. (149,366.) Aug. 25.
 4161 (1919). Jensen. Preservation of metals and metallic articles. (149,371.) Aug. 25.
 13,420 (1919). Deziel. Process of heating metal objects. (149,793.) Sept. 1.
 18,048 (1919). Wellman Smith Owen Engineering Corp., and Kemp. Continuous reheating furnaces. (149,509.) Aug. 25.

XI.—ELECTRO-CHEMISTRY.**APPLICATIONS.**

- Barfield and Wild. Electric furnaces. 23,537. Aug. 11.
 Bernard. Process of manufacturing insulators. 24,024. Aug. 18.
 British Thomson-Houston Co. (General Electric Co.). 24,261. *See* X.
 Brown. Electric batteries. 24,320. Aug. 21.
 Haglund. Electrolytic tanks with diaphragm cells. 24,854. Aug. 27. (Norway, 17.9.19.)
 John. Means of cooling electrodes. 24,243. Aug. 20.
 Macfarlane and Spink. Apparatus for production of ozone. 24,529. Aug. 21.
 Marino. Electrolyte for electro-deposition of metals and metallic alloys. 24,659. Aug. 25.
 Mauri. Three-phase electric furnaces. 24,198. Aug. 19.

- Morris. Electrolysis of acetone solutions. 24,210. Aug. 20.
 Oldham (G., J., & O.), and Oldham and Son. Galvanic batteries. 24,314. Aug. 20.
 Seward. Electrolytic apparatus. 24,456. Aug. 23.
 Withers (Renault). Electric furnaces. 24,789. Aug. 26.

COMPLETE SPECIFICATIONS ACCEPTED.

- 20,746 (1918) and 5894 (1919). F.I.A.T. Fabbrica Ital. Automobile Torino. Electrical furnaces. (121,485 and 134,810.) Sept. 1.
 710 (1920). Booth Electric Furnace Co. Electric furnace doors. (137,540.) Aug. 25.
 7417 (1920). August. Electric muffle furnaces. (149,893.) Sept. 1.

XII.—FATS; OILS; WAXES.**APPLICATIONS.**

- Firth. 23,815. *See* XIX.
 Heenan. Treatment of oil. 23,507. Aug. 11.
 Hicks. Soap. 23,464. Aug. 10.
 Norris. Liquid soap. 23,567. Aug. 12.

COMPLETE SPECIFICATIONS ACCEPTED.

- 10,662 (1919). Cox. *See* 1.
 11,871 (1919). Longbottom. Soap. (149,728.) Sept. 1.
 12,287 (1919). Mellersh-Jackson (Twitchell Process Co.). Process for splitting fats and oils in the manufacture of glycerin and fatty acids. (149,748.) Sept. 1.
 12,598 (1919). Nordiske Fabriker De-No-Fa Aktieselskap. Process for polymerisation of unsaturated fatty acids at low temperature. (127,814.) Sept. 1.
 15,076 and 30,653 (1919). Marlborough. Cleaning-composition. (149,111.) Aug. 18.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.**APPLICATIONS.**

- Barrett Co. Production of resins from naphthas. 23,454. Aug. 10. (U.S., 28.8.19.)
 Carpmal (Bayer and Co.). 23,551. *See* IV.
 Fischer. Production of resinous bodies from phenols and oxygen. 23,422. Aug. 10. (Germany, 24.5.19.)
 Imperial Trust for Encouragement of Scientific and Industrial Research, and Schryver. Manufacture of coating-compositions. 23,641. Aug. 12.
 Iverson and Roberts. Pigmental enamel or varnish. 23,623. Aug. 12.
 Lilienfeld. Manufacture of plastic masses. 23,867. Aug. 16. (Austria, May, 1920.)

COMPLETE SPECIFICATION ACCEPTED.

- 18,959 (1918). Iverson and Roberts. Composition impervious to oils, spirits, water, and the like. (149,365.) Aug. 25.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.**APPLICATION.**

- Paterson and Smith. Manufacture of caoutchouc etc. froth. 24,418. Aug. 23.

XV.—LEATHER; BONE; HORN; GLUE.**APPLICATIONS.**

- Elektro-Osmose A.-G. Tanning etc. 23,903. Aug. 16. (Germany, 13.10.19.)
 Long. Process for treating vegetable ivory. 23,697. Aug. 13.
 Manley. Adhesive paste. 24,591. Aug. 25.
 Ross and Walker and Sons. Treatment of skins. 24,505. Aug. 24.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Molassine Co., and De Whalley. Artificial manure or fertiliser. 24,933. Aug. 28.

COMPLETE SPECIFICATION ACCEPTED.

3990 (1920). Norsk Hydro-Elektrisk Kvaestof-aktieselskab. Nitrogenous fertilisers. (139,462.) Aug. 25.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATION.

Denington and Perry. 24,746. *See* XVIII.

COMPLETE SPECIFICATION ACCEPTED.

5512 (1919). Lenders. Method of manufacturing starch and conversion products thereof, and the products obtained therefrom. (149,374.) Aug. 25.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Bargate and Walkey. Preparation of alcohol. 23,849. Aug. 16.

Denington and Perry. Process of converting cellulosic and ligneous material into sugars. 24,746. Aug. 26.

Warwick. Apparatus for fermentation of beer etc. 23,828. Aug. 16.

COMPLETE SPECIFICATIONS ACCEPTED.

2786 (1916). Weizmann. Fermentation processes for the production of acetone and butyl alcohols. (149,355.) Aug. 25.

5512 (1919). Lenders. *See* XVII.

12,020 (1919). Dupire. Process for the manufacture of yeast from fermented musts, and more particularly the fermented musts of molasses and sugar-beet pulp. (149,438.) Aug. 25.

21,915 (1919). Anderschou. *See* XIX.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Barton. Cleansing and/or disinfecting baths etc. 23,804. Aug. 14.

Challis. Preserving eggs. 24,117. Aug. 19.

Elektro-Osmose A.-G. Method of killing micro-organisms. 24,191. Aug. 19. (Germany, 19.8.19.)

Firth. Treatment of soya beans for recovery of oil and production of synthetic milk. 23,815. Aug. 14.

Humphrey. Production of fermentable flours and bread-making mixtures. 24,856. Aug. 27.

Lyman. Manufacture of food for animals, poultry, etc. 23,486. Aug. 11.

Magrath. Water-softening apparatus. 24,662. Aug. 25.

Marshall and Sutcliffe. Method of boiling meat for production of food for animals. 23,663. Aug. 13.

Spear. Preservation of food etc. 24,370. Aug. 21.

COMPLETE SPECIFICATIONS ACCEPTED.

16,477 (1918) and 8961 (1919). Higginbottom. Apparatus for separating and purifying wheat and other cereals and their products. (149,020.) Aug. 18.

3091 (1919). Turner. Scouring of grain. (149,368.) Aug. 25.

9854 (1919). Kershaw. Treatment of refuse in refuse-destructors and the production and treatment of fluid slag obtained therefrom. (149,033.) Aug. 18.

16,592 (1919). Rogers and Frémelin. Milk-sterilising apparatus. (149,500.) Aug. 25.

21,915 (1919). Anderschou. Process of treating waste brewers' yeast to render it suitable for baking purposes. (149,533.) Aug. 25.

22,844 (1919). Hieber. Process of treating fruit juices. (149,537.) Aug. 25.

30,772 (1919). McColl, McColl, and Dryden. Installation of boiling pans for the manufacture of confectionery. (149,172.) Aug. 18.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Cockerton, and Gentosan, Ltd. Manufacture of compressed tablets from aspirin etc. 23,513. Aug. 11.

Elektro-Osmose A.-G. Process for making specific vaccines. 24,192. Aug. 19. (Germany, 19.8.19.)

Elektro-Osmose A.-G. Manufacture of specific vaccines. 24,302. 24,351. Aug. 20 and 21. (Germany, 23.8.19.)

Farbw. vorm. Meister, Lucius, und Brüning. Manufacture of methane. 23,446. Aug. 10. (Germany, 15.4.20.)

Fischer. 23,354. *See* II.

Morris. 24,210. *See* XI.

COMPLETE SPECIFICATIONS ACCEPTED.

15,775 (1919). U.S. Industrial Alcohol Co. Continuous process for the manufacture of esters. (130,968.) Aug. 18.

20,223 (1919). Chem. Fabr. vorm. Sandoz. Process for isolation of alkaloids. (134,197.) Aug. 25.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Aves and Duke. Moving-picture films. 24,931. Aug. 28.

Batty and Whyte. Photographic processes. 24,760. Aug. 26.

Guimoin-Sanson. Kinematograph films. 24,459. Aug. 23. (France, 9.6.20.)

Meissner. Process of renovating kinematograph films. 23,631. Aug. 12. (Germany, 5.2.20.)

Schwartz. Photographic printing. 24,208. Aug. 20.

COMPLETE SPECIFICATION ACCEPTED.

11,036 (1915). Sosna and Biedebach. Photographic developing processes. Aug. 18.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Explosives Trades, Ltd. (Wardenburg). Process for treating gun-cotton etc. 24,313. Aug. 20.

Silberrad. Propellants. 23,564. Aug. 11. (France, 21.8.19.)

XXIII.—ANALYSIS.

APPLICATIONS.

Atherton. Carbon dioxide recorders. 24,495. Aug. 24.

Frink. Determining viscosity of highly-viscous material. 24,264. Aug. 20.

COMPLETE SPECIFICATIONS ACCEPTED.

12,317 and 26,640 (1919). Brown and Pickston. Apparatus for automatic and continuous analysis and recording of gases. (149,752.) Sept. 1.

I.—GENERAL; PLANT; MACHINERY.**PATENTS.**

Evaporating, condensing, and cooling apparatus; Tubular —. E. Barbet et Fils et Cie. E.P. 117,070, 28.5.18. Conv., 21.6.17. Addn. to 114,838 (J., 1919, 750 A).

THE tubes are so spaced that the sheaths may be dispensed with, the desired velocity of the vapour circulating through the space between the tubes being obtained by using a mechanical blower or a fan.—W. H. C.

Cooling and liquefaction of gaseous fluids; Process and apparatus for —. O. Imray. From E. A. W. Jefferies and F. E. Norton. E.P. 148,588, 30.1.19.

By taking advantage of the latent heat of vaporisation, the heat transference is carried out with only small differences of temperature in the exchangers, thus approaching nearer to the principle of reversibility and so effecting considerable economy and enabling the preliminary compression of the working fluid to be dispensed with. (Reference is directed under Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 106,675; J., 1917, 858.) (See also Cottrell, J., 1919, 126 T.) —W. H. C.

Furnaces; Muffle and semi-muffle and like —. C. F. Priest. E.P. 148,630, 26.4.19.

THE combustion chamber is placed adjacent to but not beneath the furnace chamber, and the combustion gases pass first through flues in the side walls of the furnace chamber, then through flues in the front wall, then beneath the floor and up flues in the back wall, and lastly through flues in the roof to the stack. In the case of the semi-muffle furnace the furnace gases pass in part directly over the material under treatment.—W. H. C.

Grinding or disintegrating ores or other materials; Method of —. H. W. Hardinge. E.P. 148,637, 29.4.19.

THE material is fed into a rotating, conical tube-mill, provided with a removable lining, perforated with holes which register with one or several perforations in the shell at that part of the mill where the greatest peripheral force and grinding effect exist. The grinding is effected by balls of various sizes, which arrange themselves in layers, and the ground material is discharged through the perforations as soon as it is fine enough to pass. —W. H. C.

Drying solid liquid-containing bodies; Arrangement for —. J. W. A. Elling, Assr. to A/S. Myrens Verkstad. U.S.P. 1,347,501, 27.7.20. Appl., 21.2.19.

THE material is placed between flexible bags which extend into a drying chamber and communicate with another chamber supplied with the heating medium. The drying chamber is maintained at a lower pressure than the heating medium chamber. —W. H. C.

Dryer; Tunnel —. Internationale Ges. für Trockenanlagen m.b.H. G.P. 322,019, 6.6.18.

THE cars in which the material is carried through the dryer are divided into compartments by transverse partitions. Separate channels are provided in each for the conveyance of air supplementary to the drying air proper, and when the cars are pushed together these form a continuous passage-way through which the supplementary air flows to mix with the drying air. Openings for air are also provided in these channels at the front end of each car, and these lead to the separate compartments of the

car, so that the supply of supplementary air can be accurately controlled.—J. S. G. T.

Filtering; Method of and apparatus for —. N. B. Down, Assr. to Braden Copper Co. U.S.P. 1,318,159, 3.8.20. Appl., 2.1.20.

A SUBSTANTIALLY dry filter-cake is obtained by the use of a curved filtering surface. When the cake is of sufficient thickness the unfiltered liquid is withdrawn and a gaseous medium is passed through the cake. The curvature of the surface is such that any cracks that may form as the material dries do not extend through to the filtering surface. —W. H. C.

Filter; Drum —. H. Hencke. G.P. 318,843, 7.6.16.

THE filter consists of a cylindrical revolving drum mounted on trunnions; the channels leading from the several compartments of the drum to the suction chamber can be closed by means of taps at any desired part of the periphery of the drum, so that the suction can be interrupted, if necessary, while the drum is revolving and solutions of different concentration withdrawn from any section. The suction and pressure chambers are divided into several compartments to admit of the pressure or suction being applied successively to any desired number of compartments of the drum. The material being filtered can also be transferred successively from one compartment to another to be washed and the various solutions collected separately. —A. R. P.

Filter for removing liquids from gases and vapours. E. Christianus. G.P. 319,936, 15.6.19.

THE basket of the filter consists of a system of fine wires woven between spiral steel bands which can be compressed or expanded in order to adjust the capacity of the filter to the amount of gas to be treated.—A. R. P.

Filter-masses; Process and apparatus for washing out loose —. H. Reisert Ges. G.P. 321,815, 25.6.18. Addn. to 311,895 (J., 1919, 961 A).

TWO or more adjacent filter beds can be treated as described (*loc. cit.*) whereby a diminished supply of water to one filter bed is accompanied by an increased air supply to the same and *vice versa*, whilst a diminished water supply and increased air supply to one filter bed is accompanied by an increased water supply and diminished air supply to the other bed and *vice versa*.—J. S. G. T.

Contents of liquids; Apparatus for the recovery of the —. C. P. Grimwood. U.S.P. 1,348,409, 3.8.20. Appl., 15.7.16.

THE liquid is concentrated in a vessel having a conical bottom connected by a downwardly extending leg with a boot which is provided with a conveyor for the removal of the crystals or precipitates that form as the liquid becomes more concentrated and drop by gravity into the boot. A supply of unconcentrated liquid, introduced into the boot, rises into the leg and washes the descending solids. —W. H. C.

Electrical purification of gases; Apparatus for —. Siemens-Schuckertwerke G.m.b.H. G.P. 318,896, 6.12.18. Addn. to 318,432 (J., 1920, 355 A).

THE pit for the collection of the precipitated dust is divided into several compartments with sloping walls and arranged transversely to the direction of the current. An electrode is fixed at the junction of the dividing walls and this arrangement serves to prevent the current from disturbing the dust that has fallen into the pits.—A. R. P.

Electrical purification of gases; Apparatus for —.
Siemens-Schuckertwerke G.m.b.H. G.P. 322,188,
5.12.18.

THE transverse dimensions of the electrical fittings inserted in the gas stream are smaller than those of the gas stream. For this purpose a number of electrodes facing one another are inserted in succession in various parts of the gas stream, the size of the electrodes relative to the cross section of the channel increasing in the direction of the gas stream. This arrangement facilitates the removal of material precipitated upon the electrodes.

—J. S. G. T.

Crystallisation of salts from hot solutions; Apparatus for the —. Deutsche Solvay Werke A.-G.
G.P. 319,751, 17.12.18. Addn. to 296,635.

THE salt is detached from the various ledges and grids in the crystallising vessel by means of hammers, the tails of which are engaged by hooks or eccentric discs on an endless chain or band running through the apparatus. The vibration detaches the crystals, which fall to the bottom, where they can be collected.—A. R. P.

Treating materials; Process for — for purification purposes, either mechanical or chemical. T. Steen. G.P. 319,708, 10.11.17.

THE material together with the liquid with which it is to be treated is made to flow by means of air-lifts through a series of tanks, in which separation of the material takes place, whilst the liquid is returned to the first tank. Further quantities of liquid are introduced at one or several places below the air-lift device, so that a current of liquid is produced in the opposite direction to that of the material, which current passes from tank to tank through overflows and carries with it impurities, which are discharged from the first tank. Different liquids or liquids at different temperatures may be introduced at different parts of the system.

—J. H. J.

Packing material for gas washers and coolers. F. Trappmann. G.P. 321,768, 22.8.19.

THE packing consists of a series of overlapping inclined screens, each composed of a number of strips crossing diagonally. The upper surfaces of the diagonal strips form deflecting surfaces upon which the descending washing liquid is atomised, while its fall is hindered. The liquor collecting upon the diagonal strips runs off at the several points of intersection, and is thus uniformly distributed over the whole of the washing area of the screens.—J. S. G. T.

Separation of the constituents of gaseous mixtures [; Electrical —]. F. Skaupy. G.P. 321,769, 8.4.15.

By passage of direct current through a mixture of two gases, e.g., neon and argon, the one gas, argon, becomes concentrated at the cathode, and the other, neon, at the anode. In the case of a mixture of three gases, e.g., neon, nitrogen, and mercury vapour, one gas is concentrated at the anode, another at the cathode, and the third in the region between the two electrodes.—J. S. G. T.

Tube-mill. H. W. Hardinge. U.S.P. 1,348,642, 3.8.20. Appl., 12.9.16.

SEE E.P. 123,705 of 1918; J., 1919, 242 A.

Evaporating installations; Apparatus for regulating and maintaining a desired level of liquid in —.
E. A. Barbet. U.S.P. 1,349,114, 10.8.20. Appl., 26.3.17.

SEE E.P. 105,543 of 1917; J., 1918, 173 A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; A fundamental study of Japanese —. C. Iwasaki. Technol. Rep. Tôhoku Imp. Univ., 1920, 1, 101—135.

THE majority of Japanese coals are anthracites, semi-anthracites, and semi-bituminous. High-grade bituminous coal is scarce, but a low grade is abundant, its composition averaging 40% of volatile matter, 48% of fixed carbon, and 12% of ash. Lignite, with high ash and water content, is also abundant. Thin sections of the coals were prepared and examined microscopically by reflected and transmitted light, and also with the help of X-rays. Two components are distinguished in coal masses, "wood," and "fundamental matter," their relative quantities varying in coals from different localities. The "wood" is abundant in the margin of the coal field but scanty in the central part of it. The "fundamental matter" is that portion of the coal rich in "resin" and ash. It is composed of spherules, resin, cork, pollens, leaves, stems of grasses, etc., all plant remains, cemented by sapropel formed by the total decomposition of plant substances.—W. P.

Coals; Air-dried condition and hygroscopicity of fossil — in relation to the numerical value of their calorific power. R. Kempf. Mitt. K. Materialprüf., 1920, 37, 178—227. Chem. Zentr., 1920, 91, IV., 202.

HYSTERESIS phenomena interfere to a large degree in the attainment of equilibrium between fossil fuels and a moist atmosphere. If fossil coals are exposed to an atmosphere half saturated with water vapour until constant in weight, they will take up varying weights of water according to whether they have been exposed previously to a moist or to a dry atmosphere. This result is attributed to the colloidal nature of the coals. Results of analysis and calorific value should not, therefore, be referred to air-dried coal of unknown moisture content, but to material of known moisture content.—A. G.

Coal; Examination of — with regard to its gasification in producers. H. Strache. Mitt. Inst. Kohlenvergasung, 1919, 1, 35—37.

THE method proposed by the author in 1911 (J., 1911, 1245) and subsequently improved by Hiller (J. Gasbeleucht., 1916, Feb. 26), is eminently suitable for the examination of coals which are to be gasified in producers. The ash content of the "raw coke" is of much more importance than the ash content of the raw coal; e.g., with a coal of composition — moisture 33.1%, ash 17.3%, fixed carbon 14.7%, volatile matter 34.9%, the ash content of the coke would be 54.0%. The water content is of great importance also, since the efficiency of the producer is largely influenced thereby; but the main factor is not the percentage of moisture in the coal, but the ratio moisture: fixed carbon. The Hiller method gives not only the percentage of tar, but the calorific value of the raw coal and of the tar-free coal. The calorific values in the case cited above are as follows, calculated on raw coal: — Coke, 14.7% at 8137 cal., 1196 cal.; tar, 10.3% at 8500 cal., 876; gas (determined directly), 285; total, 2357 cal. The calorific value of the tar is 876 cal., whence the calorific value of the tar-free coal is 1481 cal. A factor is thus determined of 2357:1481—i.e., 1.59. This factor gives a good indication of the bituminous content of the coal. The fusibility of the ash can be determined by the method of Waidner and Burgess (Phys. Rev., 1906, 22, 357).—A. G.

Coals; Calculation of the efficiency of complete gasification from the analysis of —. H. Strache and A. Gross. Mitt. Inst. Kohlenvergasung, 1919, 1, 75—78, 86—89.

THE calculations are based on the carbonisation of coal and the gasification of the resulting coke to either producer-gas (semi-water-gas) or to water-gas, the coal-gas and producer-gas being afterwards mixed, and the calorific value of the mixture determined. Knowing the volume of the gas produced, the total heat units in the gas can be calculated and the efficiency determined from the calorific value and weight of coal used. Losses occur as carbon in the clinker, carbon in the flue gases, radiation and conduction losses, and finally as loss depending on the specific heat of the issuing gas and as undecomposed steam. The authors discuss the distribution of the heat required for drying and carbonising the coal and the heat evolved in the producer portion of the plant. The efficiency of such a system using raw peat as fuel is 88.6%, or 83% on the tar-free fuel.—A. G.

Lignite; Carbonisation of —. Pfeiffer. J. Gasbeleucht., 1920, 63, 420—422.

VERTICAL retorts, operated in the usual manner, are not suitable for the carbonisation of lignite. In the first trials, which were carried out with mixtures of coal and lignite, the coke delagrated violently and was dangerous to the operatives. Not more than 15% of lignite could be safely mixed with the gas coal. Later experiments were tried using lignite alone in an installation of ten vertical retorts. On withdrawing the coke, which was all under 7 mm. mesh, it burst into flame to a height of 20 m. and caused great damage. This latter problem has been solved by quenching in enclosed conduits. The coke can be burnt in household grates when admixed with 30 g. of "Camo cub" (a by-product containing sodium nitrate) per cwt. of coke. From 1 ton of lignite, 250 kg. of coke and 241.5 cb.m. of gas were produced. The cost of the gas worked out at 27.4 pf. per cb.m., as compared with 29.68 pf. per cb.m. for ordinary coal gas.—A. G.

Gas; Reduction of the carbon dioxide in — from wood carbonised in horizontal retorts. Henke. J. Gasbeleucht., 1920, 63, 422—423.

THE high percentage of carbon dioxide in the gas produced by carbonising young, freshly cut pine logs was reduced by passing the gas from the bottom and middle tiers of retorts through the top tier, the latter being kept full of glowing wood charcoal, which was replenished when necessary from the bottom retorts. The carbon dioxide content was reduced from 16.4—18.6% to 5.4—9.8%, whilst the carbon monoxide increased from 22—27% to 34.4—41.8%. The liquor produced was sent to waste, as its content of ammonia was very small, and of pyroligneous acid only 0.5%. The viscous tar fetched only the same price as coal tar.—A. G.

Coke; Hygroscopicity of by-product —. W. A. Selvig and B. B. Kaplan. J. Ind. Eng. Chem., 1920, 12, 783-784.

FOUR samples of pulverised by-product coke were dried at 105° C., and exposed for 1 to 24 hrs. to the laboratory air (average humidity 20—27%). From 0.14 to 0.54% of moisture was absorbed in 7 hrs. To prevent analytical error from this source, the moisture in the laboratory sample should be determined and allowed for in calculating the results on a dry basis.—C. A. M.

Heat of combustion of benzene, toluene, aliphatic alcohols, cyclohexanol, and other carbon compounds. T. W. Richards and H. S. Davis. J. Amer. Chem. Soc., 1920, 42, 1559—1617.

THE heats of combustion of the following substances

have been redetermined, and the values expressed in 18°-calories per g.: sucrose, 3943; benzoic acid, 6320; naphthalene, 9614; benzene, 10,014; toluene, 10,155; tertiary butylbenzene, 10,434; cyclohexanol 8882; di-isamyl, 11,339; methyl alcohol, 5326; ethyl alcohol, 7101; propyl alcohol, 8033; *n*-butyl alcohol, 8615; isobutyl alcohol, 8590.—J. F. S.

Acetylene; Combustion of — in motors. F. Haber. Z. Elektrochem., 1920, 26, 325—329.

THE use of acetylene in place of benzene or petrol is an economic possibility if the increased production of carbide is rendered possible by improved output of coal. The utilisation of acetylene is notably better than that of benzene, since the former is completely, the latter very incompletely, burnt in motor engines. The usual engines with a pre-compression of 1.4:5 can be used. It is, however, necessary to provide sparking plugs in which the metallic portions extending into the combustion chamber are as well cooled as possible; insulating material of low heat conductivity should only be used in the more remote parts of the plug. With pure acetylene, use of an excess of air cannot be avoided in practice, and in consequence the efficiency of the machine is not quite so good as with benzene. A mixed fuel in which another combustible substance in addition to acetylene is used, with the object of depressing the inflammability of the latter, appears particularly promising.—H. W.

Gasoline from natural gas. II. Use of charcoal in determining the gasoline content of natural gas. R. P. Anderson and C. E. Hinckley. J. Ind. Eng. Chem., 1920, 12, 735—738.

HIGHLY activated gas-mask charcoal (8- to 14-mesh) is an efficient absorbent of gasoline. The gas is passed through two glass tubes about 0.8 in. diam., each containing about 8 in. of the charcoal. Variations from 20 to 50 cb. ft. per hr. in the speed make little difference in the case of gas containing 0.15 gall. of gasoline per million cb. ft. For the amount of charcoal specified, the vol. of gas used in a test may vary from a fraction of 1 cb. ft. to 30 cb. ft. or more. The vol. of gasoline removed by the first tube should be between 5 and 10 c.c., but the second should not contain more than a small fraction of 1 c.c. Drying the gas or the charcoal increases the yield by 5 to 8%, and variations in the temperature make but little difference. The gasoline may be recovered by covering the charcoal with mineral oil and distilling. Only 60% is recovered by dry heat *in vacuo*. A portable apparatus for field use is described.—C. A. M.

Bitumens; Extraction of — from mineral aggregates. M. R. Walczak and H. I. Rice. J. Ind. Eng. Chem., 1920, 12, 738—740.

BITUMENS, and especially tar bitumens (sp. gr. about 1.2), may be separated from mineral aggregates (sp. gr. about 2.70) by the use of a solution of a practically inert salt having a sp. gr. intermediate between the two substances. Two kg. of the material—e.g., bituminous concrete—is introduced into a vertical copper still, the lid of which is screwed down, and is connected with a flanged glass tube, about 1.5 in. diam., fitted by means of a cork into a reflux condenser. Sufficient sodium carbonate solution (sp. gr. 1.27—1.28) is added to make the surface of the liquid just visible, and the flask heated until the bitumen accumulates as a layer in the upper portion of the tube. The reflux condenser is washed with 10 c.c. of the sodium carbonate solution, and then closed, and the still rapidly heated, so as to expel the liquid bitumen through an overflow tube, in the cork, which has meanwhile been opened. The material is collected in a large test-tube, centrifuged for 15 min., the upper bituminous layer decanted, and its consistency determined. The addition of about 100 g. of

sodium bicarbonate to the sodium carbonate solution will promote the separation of bitumens which adhere to the mineral aggregate.—C. A. M.

PATENTS.

Coal; Coking of — with recovery of by-products. E. Fleischer. G.P. 298,085, 9.12.16.

A COMBUSTIBLE gas, as free as possible from steam or carbon dioxide, is introduced above 900° C. into the bottom of a furnace, which is charged above with coal, whilst at the same time air and steam are blown into the furnace at a higher level in such quantities that the temperature of the gases which are then burned does not exceed 600°–800° C. Good yields of coke and distillation products are thus obtained.—C. A. M.

Coal; Conversion of — into soluble organic compounds. F. Fischer. G.P. 306,471, 20.5.16.

COAL or a mixture of coal and other substances is treated with ozone, avoiding excessive heating, until the coal is largely converted into substances soluble in water. The aqueous solution when evaporated leaves a hygroscopic residue which has a strong odour of caramel, and is soluble in alcohol but nearly insoluble in ether.—C. A. M.

Coal; Decomposition of —. Rütgerswerke A.-G. G.P. 320,056, 10.8.18.

COAL is softened and decomposed when heated with a small amount of coal tar oils of high b. pt., soluble oils and part of the coal being dissolved to form a tar-like fluid. The insoluble portions may be separated by filtration, sedimentation, etc., after diluting the mass with more of the solvent, or with other organic liquids, such as oils containing carbolic acid, or tar oils of b. pt. 250°–360° C. —C. A. M.

Gas; Apparatus for making —. D. E. Campbell. E.P. 148,027, 29.5.19.

A HYDROCARBON oil is projected at high speed against a breaker plate, air being admitted at the same time or alternately with the oil. The mixture of air with the gas thus produced passes on through a chamber in which oil globules are separated. Means are provided for returning this oil to the jet, and the gas is stored in a gasometer which actuates the air- and oil-nozzle valves.—A. G.

Gas producers. J. F. Wells. E.P. 148,057, 22.8.19.

THE producer is divided into upper and lower compartments by a transverse plate, having an aperture furnished with a bell or cone extending into the lower compartment. The upper compartment acts as a fuel hopper, the fuel being fed into the lower chamber by a vertical feed-rod on which are teeth arranged helically. The producer chamber is provided with an inclined grate and water seal.—A. G.

Ammonia; Process for obtaining — from gases obtained by dry distillation. Gebr. Hinselmann. G.P. 320,415, 1.10.12.

THE gas is cooled in a scrubber before being led into an acid bath, and the hot condensed liquor, after separation of tar, is stirred with milk of lime to produce ammonia gas without the use of steam and with the employment of only a small amount of external heat.—L. A. C.

II.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Kelp; Potash from —. III. Preliminary examination of kelp distillates. G. C. Spencer. J. Ind. Eng. Chem., 1920, 12, 786–792.

LOW-TEMPERATURE distillation of kelp (243°–305° C.) yielded 1.1% of crude tar. The dried tar (45–65% of the crude tar) when fractionally distilled yielded 34.2% of oil, 10.6% of aqueous distillate, and 55% of pitch (sp. gr. 1.11; m.p. 103° C.). The oil was separated into 8.5% of oil soluble in ammonia and acids, 10.8% of tar acids, and 14.9% of residual oil. The aqueous portion yielded 0.1% of ammonia. High temperature kelp tar (800°–900° C.) yielded similar products and a residual pitch (sp. gr. 1.17; m.p. 130° C.) containing 3.5–5.15% nitrogen, and yielding Prussian blue when fused with iron turnings and caustic alkali. The first distillates contained variable amounts of oils and phenolic substances. The tar acids had sp. gr. 1.024–1.041. When mixed with the residual oil, alkali solution, and rosin they gave a disinfectant $\frac{1}{4}$ times as toxic to a wood-destroying fungus as coal tar creosote. The aqueous distillate (sp. gr. 1.01–1.065) yielded 0.76% ammonia, and left 3.66–7.93% of residue, which, when distilled, gave a main fraction of reddish colour, somewhat less viscous than glycerol, with sp. gr. 1.3431 at 23° C., n_D^{20} = 1.5013, and composition $C_{10}H_{18}O_6$. It appeared to be a hydroxyl compound of the glycol or glycerol series. It might be of value as a glycerin substitute for mechanical purposes.—C. A. M.

Decolorising carbon. Bock. See XVII.

III.—TAR AND TAR PRODUCTS.

Coal tar and pitch; Free carbon in —. R. Hodurek. Mitt. Inst. Kohlenvergasung, 1919, 1, 9–10, 19–21, 28–30.

THE quantity of pitch produced by the distillation of any tar may be represented by the formula $x = 100k/K$, where k is the free carbon content

of the tar and K that of the pitch; in practice the value of x is always too high. Methods for the estimation of free carbon in tar and pitch by extraction with various solvents are all open to the objection that the results vary according to the solvents used, the carbon separated being of a different degree of purity in each case. The carbon separated out by various solvents is always more or less contaminated with bituminous substances, which the solvent is not able to dissolve or which may even be precipitated from the tar. Such bituminous substances (C_{II}) are precipitated from tar by alcohol, methyl alcohol, benzol, petroleum, benzine, toluol, xylol, pyridine, ether, acetone, and acetic acid, but not by aniline, quinoline, phenol, cresols, nitrobenzene, naphthalene, and anthracene oils. The precipitated bituminous substances are soluble in anthracene oil. They are fusible and possess great binding power, and their evaluation is therefore important if the pitch is to be used for briquetting. For determining the true free-carbon content (C_I), $C_I + C_{II}$ is first estimated by treatment with benzol. The C_{II} in the filtered tar is then estimated in a similar manner and the difference gives C_I , the true "free" or "suspended" carbon. In a sample of tar from Zeche Schwerin the content of C_I (true free carbon) determined by the author's method was 1.50%, whereas results ranging from 3.74 to 6.80% were obtained by other known methods. In general, gas tars contain more C_I than C_{II} , whilst coke-oven tars contain more C_{II} than C_I . During the distillation of tar to pitch (amounting to 57% of the tar) the C_{II} increased by 4.22%, whilst the free carbon C_I increased only by 0.37%. On further distillation to yield 48%, 40%, and 30% of pitch respectively, the C_I increased to 6.68%, 16.80%, and 48.70%, whilst the C_{II} increased to 24.90%, 37.40%, and then diminished to 26.80%. With increase in temperature, the bituminous substances which are at first formed during distillation undergo decomposition with the production of more free carbon. Hence the formula for the calculation of the pitch yield should be $x = 100k/K + C$, where C is a constant depending on the process used, the type of apparatus adopted, and the finishing temperature of distillation.—A. G.

o-Chlorodinitrotoluenes. I. G. T. Morgan and H. D. K. Drew. Chem. Soc. Trans., 1920, 117, 784—793.

THE product of the nitration of *o*-chlorotoluene with nitric-sulphuric acid contains four isomerides in the following proportion: 3.5-dinitro-2-chlorotoluene 55—60%, 5.6-dinitrochlorotoluene 18—20%, 4.5-dinitrochlorotoluene 18—20%, and 4.6-dinitrochlorotoluene 1—2%. The 4.5-dinitro-2-chlorotoluene, m.p. 88.5° C., is more readily obtained as the main product of the nitration of 2-chloro-4-nitrotoluene, whilst about 12% of the 4.6-dinitroisomeride, m.p. 49° C., is formed in the same reaction. The further nitration of 2-chloro-6-nitrotoluene gives a 90% yield of the 5.6-dinitro compound. The dinitro-2-chlorotoluenes contain labile acid radicles displaceable by amino groups. In this reaction addition of ammonia to the aromatic compound precedes substitution, and the first phase of the reaction is accompanied by the development of intense colorations.—G. F. M.

Benzol light oils; Recovery of crude products from —. F. Tschudy. U.S.P. 1,348,606, 3.8.20. Appl., 5.7.17.

BENZOL light oils are distilled continuously at the highest temperature required to vaporise the low-boiling homologues. The high-boiling constituents condensed from the vapour by partial fractionation are redistilled in a separate vessel, and the undensified low-boiling constituents are further fractionated by dephlegmation in successive stages.

—L. A. C.

Oils; Manufacture of viscous — readily converted into water-soluble products. Tetralin, G.m.b.H. G.P. 319,799, 4.12.17.

Viscous oils which can be readily sulphonated to yield water-soluble products are prepared by treating hydrogenated naphthalenes with alkyl halides or acid chlorides with or without the addition of condensing agents. Tetrahydronaphthalene forms with benzyl chloride and zinc chloride at 120° C. an oil with b.p. 200°—202° C. (20 mm.), and viscosity 3.2° (Engler) at 50° C.; with chlorinated xylol, an oil of viscosity 5°—6° (Engler) at 20° C.; with benzoyl chloride and a little phosphorus pentoxide at 280°—300° C., an oil with b.p. 228°—230°, and with chlorinated tetrahydronaphthalene and a little phosphorus pentoxide, an oil with b.p. (15 mm.) 240°—243° C., viscosity 35.5° (Engler) at 50° C., sp. gr. (15° C.) 1.104, and flash point about 200° C. From decahydronaphthalene, benzyl chloride, and a little phosphorus pentoxide at 170°—190° C., a very viscous, dark green oil is obtained.—L. A. C.

Alkylamino compounds [alkylaminoanthraquinones]; Manufacture of aromatic —. F. W. Atack and W. N. Haworth. E.P. 147,964, 22.1.19.

AMINOANTHRAQUINONES are alkylated by treatment with a dialkyl sulphate in solution in a high-boiling neutral medium, such as nitrobenzene or tetrachloroethane, in presence of a mild alkali such as sodium carbonate. Thus 20 pts. of 1-aminoanthraquinone may be dissolved in 216 pts. of nitrobenzene and 20 pts. of sodium carbonate added, the mixture being heated to boiling under a reflux condenser, whilst 17½ pts. of dimethyl sulphate is added during a period of about 2 hrs. A yield of about 87% of 1-methylaminoanthraquinone may be recovered from the reaction mixture. When 5 pts. of 2-aminoanthraquinone is treated in the same way with 6 pts. of dimethyl sulphate 2-dimethylaminoanthraquinone is the chief product.

IV.—COLOURING MATTERS AND DYES.

Benzanthrone; Some properties of —. A. G. Perkin. Chem. Soc. Trans., 1920, 117, 696—708.

SOLUTIONS of benzanthrone in glacial acetic acid yield red or scarlet oxonium salts of the type $(C_{14}H_8O)_2HFeCl_4$ with ferric, stannic, and platinum chlorides. They are all readily dissociated on treatment with water. Benzanthrone dissolves in concentrated sulphuric acid with a deep red coloration, but no sulphate could be isolated. Hydroxy-

benzanthrone, however, prepared from 2-hydroxy-anthranol, sulphuric acid, and glycerol, gave scarlet needles of the sulphate when its acetyl compound in acetic acid was treated with concentrated sulphuric acid. Methoxybenzanthrone prepared by the action of methyl sulphate on the above hydroxy compound formed yellow needles, m.p. 198°–199° C., and gave not only oxonium sulphates, ferrichlorides, etc., but also a red hydrochloride and hydrobromide. The *o*-dihydroxybenzanthrone derived from desoxylizarin—the anthranol corresponding with alizarin—was prepared and purified by acetylation, and the subsequent decomposition of the diacetyl derivative, m.p. 199°–201° C. This dihydroxybenzanthrone, for which the name benzalizarin is suggested, forms orange-red plates, m.p. 309°–310° C. (with decomp.), and maroon-coloured oxonium salts with sulphuric and the halogen acids. It dyes mordanted wool shades similar to those given by alizarin, but of a slightly more orange tint. As benzalizarin readily gives a dimethyl derivative, it is concluded that it must be a 7,8-dihydroxybenzanthrone, and the monohydroxybenzanthrone above mentioned will accordingly be the 7-hydroxy compound. On oxidation in acetic acid solution with chromic acid benzanthrone gives anthraquinone-1-carboxylic acid in excellent yield.—G. F. M.

Sulphide dyes; Constitution of yellow —. J. K. Mazumder and E. R. Watson. Chem. Soc. Trans., 1920, 117, 830–834.

THE yellow sulphide dye obtained by the fusion of diformyl-*m*-toluylenediamine with sulphur, having the empirical formula $C_{11}H_{14}N_4S_{6.27}$, yields, on oxidation with alkaline permanganate, a substance of the composition $C_{11}H_{14}O_2N_4S_{3.68}$. On the assumption that this substance is a sulphonic acid, it is deduced that the dye complex formed from 12 mols. of diformyl-*m*-toluylenediamine contains 5 -S.SH groups and 5 -S.S.SH groups, all of which are converted into sulphonic groups on oxidation. The remaining sulphur atoms and half the nitrogen atoms would accordingly be involved in thiazole rings. The action of reducing agents, with the exception of phosphorus and hydriodic acid which resulted in the formation of two bases, gave no definite products.—G. F. M.

PATENTS.

Dyes; Manufacture of —. R. Maclaurin. E.P. 148,617, 24.4.19.

THE ammonia liquor, or the liquor obtained by washing with water the oils obtained in the low-temperature carbonisation of bituminous fuels, either with or without removal of free ammonia, is made sufficiently acid to decompose any sulphides, and is then filtered to remove tarry and precipitated matter. Sufficient ferrous sulphate is added to the liquor, in which any free acid has been neutralised, to throw down a slate-coloured precipitate which dyes wool in an alkaline bath a slate colour, fast to light, which by after-chroming is converted to a brown shade. The liquor remaining after removal of this precipitate is acidified and treated with sodium nitrate and ferrous sulphate, whereby a precipitate is formed which dyes iron mordanted wool a green colour.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose acetate. H. J. H. Fenton and A. J. Berry. Proc. Camb. Phil. Soc., 1920, 20, 16–22.

VARIOUS substances have been tried as substitutes

for acetone as solvent. The authors find no objection to esters as dope constituents, and as far as weak acids are concerned, tensile strength determinations gave excellent results, fabrics doped with acetic acid as the principal solvent comparing most favourably with others. No general conclusion can be drawn as regards the chemical nature of a liquid and its solvent action on cellulose acetate, but there appears to be some relation between the dielectric constant and solvent action. For the determination of the acetyl group the authors prefer Ost's method of cold alkaline saponification (J., 1912, 713). Cellulose acetate differs considerably from cellulose in its power of adsorbing various dyestuffs.—W. G.

Cellulose phthalate; Preparation and properties of —. H. A. Levey. J. Ind. Eng. Chem., 1920, 12, 743–744.

CELLULOSE phthalate is obtained by heating cellulose (preferably modified by treatment with an acetic acid solution of chlorine) for 24 hrs. at 70° C. with phthalic anhydride and zinc chloride in the smallest possible quantity of diethyl phthalate, and washing and drying the ester *in vacuo* at not more than 70° C. The product is practically insoluble in all common solvents. (Cf. J.C.S., Oct.)—C. A. M.

Thymol from p-cymene. Phillips and Gibbs. See XX.

PATENTS.

Straw and the like; Method of treating — for making paper-pulp. E. E. Werner. U.S.P. 1,347,979, 27.7.20. Appl., 5.5.19.

STRAW or the like is treated with an excess of an alkaline solution, and, before further treatment, a portion of the solution is expressed to reduce the alkalinity of the material to a given degree.

Wood-pulp and cellulose manufacture; Removing water from the pulp sheet in —. Apparatus for extracting water from wood-pulp and the like. R. E. Wagner, Assr. to Aktiebolaget Karlstads Mekaniska Verkstad. U.S.P. 1,347,723–4, 27.7.20. Appl., 19.7.17 and 22.1.18.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Mordant or dye and process of making the same. G. M. Lopez and A. Quaglia. U.S.P. 1,348,431, 3.8.20. Appl., 24.6.19.

THE fruit of a tree of the genus *Guaiacum* is desiccated until volatile juices are removed and the gummy portion is dried, the product is then ground and screened, and the powder is compressed.

—L. A. C.

β-Naphthol preparations; Manufacture of — for the production of a bluish Para Red and other azo colours on the fibre. Chem. Fabr. Grünau Landshoff und Meyer A.-G., and C. Bochter. G.P. 320,178, 25.4.15.

β-NAPHTHOL for the production of azo colours on the fibre is mixed with about 1% of a substantive dye capable of coupling with *p*-nitraniline or other developers, such as Diaminenitrazol Violet, Para Violet, Parazol Violet, or the like. The brown shade of the developed dye is thus avoided, and the liability of the *β*-naphthol to sublime is diminished.

—L. A. C.

Dyeing, washing, scouring, sizing, bleaching, and mercerising yarn in hank form; Machine for —. J. S. and S. S. Lord. U.S.P. 1,348,724, 3.8.20. Appl., 11.4.19.

SEE E.P. 121,075 of 1918; J., 1919, 71 A.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric and nitric acids; Freezing points of mixtures of —. W. C. Holmes. J. Ind. Eng. Chem., 1920, 12, 781—783.

THE freezing point of sulphuric acid is at first lowered by the addition of nitric acid, the minimum (−18.2° C.) being reached with 5.4 HNO₃. On continuing the addition the freezing point rapidly rises to a maximum at +2.3° C. with 10.8 HNO₃. It is probable that a definite compound 5H₂SO₄, HNO₃ is then present. (Cf. J.C.S., Oct.)

—C. A. M.

Hydrochloric acid; Indirect method of determining specific heat of dilute solutions, with preliminary data concerning —. T. W. Richards and A. W. Rowe. J. Amer. Chem. Soc., 1920, 42, 1621—1635.

THE specific heats of dilute solutions of hydrochloric acid are:—HCl.10H₂O, 0.752; HCl.20H₂O, 0.849; HCl.25H₂O, 0.8776; HCl.50H₂O, 0.9320; HCl.100 H₂O, 0.9664; HCl.200H₂O, 0.9812, and HCl.400H₂O, 0.9905. (Cf. J.C.S., Oct.) J. F. S.

Sulphates of sodium; Action of alcohol on the —. G. S. Butler and H. B. Dunncliff. Chem. Soc. Trans., 1920, 117, 649—667.

DRY ethyl alcohol, and also methyl, *n*-butyl, and amyl alcohols, act on dry sodium bisulphate with the formation of an intermediate sulphate, Na₂SO₄.NaHSO₄, and liberation of sulphuric acid which is subsequently partially converted into alkyl hydrogen sulphate. Potassium bisulphate is not decomposed in this way. Moist alcohol completely decomposes sodium bisulphate, giving the intermediate salt and finally the normal sulphate, which is sparingly soluble in moist alcohol. Alcoholic sulphuric acid reacts with normal sodium sulphate in the cold (18° C.) with the formation of an acid sulphate, the amount of the interaction increasing with the strength of the alcoholic sul-

phuric acid employed. Sodium bisulphate is converted by alcoholic sulphuric acid into the intermediate sulphate, Na₂SO₄.NaHSO₄, if the strength is below 20%, whilst if it is 30% or more the salt Na₂SO₄.2NaHSO₄ is probably produced, but if so, this compound is slowly decomposed by extraction with pure dry ether and the intermediate sulphate remains. The intermediate sulphate, Na₂SO₄.NaHSO₄, is also produced by heating dry sodium sulphate with dry sodium bisulphate, and it constitutes nitre cake, either alone, or mixed with the bisulphate or normal sulphate, according as the acidity is equal to, greater than, or less than 18.7% of sulphuric acid.—G. F. M.

Potassium salts; Separation of — from the coke or ash obtained from cane molasses. G. E. G. von Stietz. Archief Suikerind. Nederl.-Indië, 1920, 28, 519—533. Int. Sugar J., 1920, 22, 467.

IF the coke or ash obtained from cane molasses be leached with a large amount of water (giving a liquor of sp. gr. about 1.07), the salt obtained on evaporation will be composed of:—K₂CO₃, 70—75; K₂SO₄, 15—20; KCl, 3—7; K₂SiO₃, 1—3; and insoluble matter, about 1%. If less water be used (so as to give a liquor of sp. gr. 1.38) the extract is purer, and contains about 90% K₂CO₃, and less than 1% K₂SO₄. Preferably, the material is extracted with an excess of water, and fractionally crystallised. From 100 tons of molasses 2.0% of pure potassium sulphate and about 4.6% of potassium carbonate of 90% purity are obtained.

—J. P. O.

Hydrosulphides; Volumetric determination of — in the presence of sulphides, thiosulphates, and sulphites. A. Wöber. Chem.-Zeit., 1920, 44, 601.

SODIUM hydrosulphide reacts with mercuric chloride according to the equation

thiosulphate reacts similarly with the liberation of 2 mols. of sulphuric acid, whilst sulphide and sulphite yield neutral mixtures (cf. Sander, J., 1916, 307). If a solution containing a mixture of the sulphur compounds is treated with an excess of mercuric chloride solution, titration of the resulting acidity gives a measure of the hydrosulphide plus the thiosulphate (a); a similar titration after the hydrosulphide and sulphide have been eliminated by treatment with zinc carbonate gives the acidity due to thiosulphate (b); the difference between a and b is the acidity due to hydrosulphide. Sulphite and hydrosulphide react with iodine with the formation of an equivalent quantity of hydriodic acid,

and the iodometric method described by Sander (*loc. cit.*), with allowance for the hydrosulphide, may be used for the determination of the sulphite, sulphide, and thiosulphate.—W. P. S.

Ferric oxide; Carrying down of copper oxide and nickel oxide by precipitates of —. E. Toporescu. Comptes rend., 1920, 171, 303—305.

WHEN ammonia solution is added to a solution of a ferric salt containing in addition either a copper salt or a nickel salt a certain amount of copper oxide or nickel oxide is always carried down with the ferric hydroxide, the amount depending on the relative proportions of the two salts present and the amount of ammonia added. These oxides cannot be removed from the precipitate by washing or by treatment with strong ammonia.—W. G.

Sulphate of manganese peroxide; Preparation of — and oxidation of toluene by it. M. Nakao. J. Pharm. Soc. Japan, 1920, No. 459, 409—426.

THE best conditions for the preparation of sulphate of manganese peroxide (E.P. 17,981 of 1903; J.,

1904, 749) are as follows:—concentration of sulphuric acid, 55%; temperature, 55° C.; current density, 5–16 amp. per sq. m. The electrolyte in the positive compartment is agitated by a stirrer revolving 800 times per minute. After 20 hrs. the yield of the product begins to decrease. The maximum yield is about 20.8% in the whole liquid, which corresponds to 73.43% of that calculated from the manganous sulphate. Sulphate of manganese peroxide is stable in about 55% sulphuric acid, but unstable in the concentrated acid and above 80° C. By vigorously agitating excess of toluene with a sulphuric acid solution of sulphate of manganese peroxide at 50° C. (E.P. 17,952 of 1903; J., 1904, 910) a 61.45% yield of benzaldehyde was obtained. The manganous sulphate in the waste liquor may be used for the preparation of the peroxide.—K. K.

Phosphates of heavy metals; Determination of phosphoric acid in —. F. Seeligmann. Chem.-Zeit., 1920, 44, 599.

TEN g. of the powdered sample is heated at 90–95° C. for 15 mins. with 12 g. of sodium hydroxide solution (sp. gr. 1.383); the mixture is then diluted with four times its volume of water, boiled, cooled, diluted to 1 l. and filtered. An aliquot portion of the filtrate is acidified with acetic acid and titrated with uranyl acetate solution.—W. P. S.

Stannic chloride; Manufacture of —. S. Ochi. J. Chem. Ind. Japan, 1920, 23, 583–594.

By the action of dry chlorine on metallic tin below 114° C., a yield of 87% of stannic chloride is obtained. A 93% yield is obtained by acting on metallic tin with sulphur monochloride, then removing sulphur monochloride from the crude product by boiling with stannous chloride and distilling. By the action of chlorine upon tin at 100° C. in presence of sulphur monochloride (35% of the weight of tin) as catalyst an 88% yield is obtained. Stannic chloride may also be prepared in about 90% yield by the action of sulphur monochloride upon dry stannous chloride, stannous oxide, stannous sulphide, or stannic sulphide. Tin compounds in the residues may be recovered as sulphide and then as chloride by the action of sulphur monochloride. A mixture of stannic chloride and 34.6% of water forms a hydrate, $\text{SnCl}_4 \cdot 5\text{H}_2\text{O}$, m.p. ca. 60° C., which is soluble in water and convenient for use and transportation.—K. K.

Iodic acid and its anhydride; Preparation of —. A. B. Lamb, W. C. Bray, and W. J. Geldard. J. Amer. Chem. Soc., 1920, 42, 1636–1648.

IODINE pentoxide is best prepared, even on a manufacturing scale, by the oxidation of iodine to iodic acid by means of 24–26% chloric acid solution, evaporation of the solution, and dehydration of the iodic acid. A slight excess (3%) of chloric acid is used which destroys the hydrochloric acid formed in the process. The yield is theoretical. The chloric acid solution is prepared directly by the action of sulphuric acid on a solution of barium chlorate. (Cf. J.C.S., Oct.)—J. F. S.

Colloidal catalysts (platinum, palladium); Ageing of —. G. de Rocasolano. Comptes rend., 1920, 171, 301–303.

THE catalytic activity of electrosols of platinum and hydrosols of palladium in regard to the decomposition of hydrogen peroxide increases at first with age until it reaches a maximum and then decreases.

PATENTS.

Sulphuric acid; Process for extraction of arsenic and other impurities from —. G. K. Davis. E.P. 146,598, 7.4.19.

SULPHURIC acid issuing from a denitration plant, at sp. gr. 1.600–1.750, is cooled and passed into an apparatus (E.P. 2113 of 1909; J., 1910, 79) in which it is rapidly saturated with hydrogen sulphide at a temperature not exceeding 18° C. Without allowing the arsenious sulphide to settle, the acid is then passed through a filter of the vacuum or pressure type. By this process decomposition of the acid by the hydrogen sulphide, with consequent solution of arsenious sulphide by the sulphurous acid, is avoided.—W. J. W.

Basic sulphate of chrome; Production of — and its application to tanning and other uses. J. Morel. E.P. 148,615, 22.4.19.

SOLUTIONS of alkali bichromate or normal chromate, without any addition of sulphuric acid or other reagent, are reduced with sulphurous acid gas to give a basic sulphate of chromium $\text{Cr}_2(\text{SO}_4)_2(\text{OH})_2$, which is used for chrome tanning.—D. W.

Salt; Process for purifying —. F. J. Wood, Assr. to Worcester Salt Co. U.S.P. 1,346,624, 13.7.20. Appl., 30.12.16.

BRINE flowing from the last of a series of vacuum pans is heated by a steam jet to precipitate impurities, filtered, and returned to the first pan and then to the succeeding pans, salt being precipitated in each of the pans.—W. J. W.

Pickle liquor; Treating waste —. A. T. Weaver, E. W. D. Laufer, and E. von Wintzingeroede, Assrs. to The American Steel and Wire Co. U.S.P. 1,348,462, 3.8.20. Appl., 3.8.16.

PICKLE liquor containing sulphates is sprayed into a furnace, and the evolved water, sulphurous and sulphuric acid gases are condensed in the presence of steam, metallic oxides being deposited on the floor of the furnace.—J. W. D.

Lime; Process of treating —. A. E. Horn. U.S.P. 1,348,494, 3.8.20. Appl., 12.6.19. Renewed 28.6.20.

QUICKLIME is treated with a quantity of water sufficient to produce a dry powder, and a fatty acid is added before the hydration is completed.—W. P. S.

Calcium oxide; Manufacture of compact blocks of — from calcium hydroxide sludge. Farbenfabr. vorm. F. Bayer und Co. G.P. 320,422, 27.3.17.

CALCIUM hydroxide sludge, produced, e.g., by slaking quicklime, or decomposing calcium carbide or crude calcium cyanamide, is partially freed from water, compressed into blocks, and calcined.

—L. A. C.

Magnesium carbonate; Preparation of light basic —. "Lipsia," Chem. Fabr. G.P. 302,413, 7.3.16. Addn. to 301,723 (J., 1920, 406 A).

AMMONIUM magnesium carbonate is precipitated from potash end-liquors by the addition of ammonium carbonate, and the precipitate, after washing, is converted into basic magnesium carbonate by boiling with water. A very light *magnesia alba*, free from potassium compounds and chlorides, is thereby produced.—L. A. C.

Nitrogen oxides and similar gases; Condensing —. H. Petersen. G.P. 302,533, 3.1.17.

THE moist gases are led into the top of a reaction tower filled with packing material, and pass out at the lower end. The time of contact of the gases with the liquor condensing on the packing is thereby increased.—L. A. C.

Ammonia; Production of — from ammoniacal liquor and milk of lime. Production of hydrogen sulphide from the waste liquor from ammonia generators. C. Otto und Co., G.m.b.H. G.P. (a) 303,832 (Addn. to 299,621), 23.6.17, and (a) 302,562, 3.7.17.

(A) AMMONIA is liberated from a mixture of ammoniacal liquor and milk of lime by means of steam in a reaction tower provided with ring packing (G.P. 299,621; J., 1920, 448 A). The ammoniacal liquor is led into the tower at a point about two-thirds of its height, and the milk of lime flows in at the top; the upper third of the tower then serves as a scrubber for the ammonia liberated in the lower portion. (n) Hydrogen sulphide is recovered from the waste liquor obtained in the above and like processes by passing the liquor down a similar tower and subjecting it to the action of a counter-current of steam and carbon dioxide.—L. A. C.

Gases containing sulphur compounds; Production of —. Harburger Chem. Werke Schön und Co., and W. Daitz. G.P. 307,081, 1.3.17. Addn. to 306,441

THE addition of magnesium sulphate to the mixture which is calcined to produce a mixture of calcium oxide and sulphide (J., 1920, 570 A) assists the production of calcium oxide, improves the quality of the magnesia sludge, and increases the proportion of sulphur dioxide to hydrogen sulphide in the gases.—L. A. C.

Hydrogen; Manufacture of —. J. Harger. E. P. 147,235, 2.4.18.

PRODUCER-GAS is enriched by passing it at 900°–1200° C. over briquettes of carbon, sodium carbonate, and iron, by which means it is freed from sulphur compounds, tar fog, and hydrocarbons, and its nitrogen content is reduced to 40–50%. The hot gas is passed through a furnace packed with iron round the outside of a vessel containing iron ore, to a heat-interchanger and thence to a purifier from which it is brought back through the heat interchanger into contact with the ore. Part of the spent gases from the reduction phase may be returned to the producer and part may be utilised for heating the briquette chamber. The combustion of part of the spent gases may be utilised for heating a water tube heater to supply steam, and water condensed from the gases in the oxidation stage may be converted into steam in the water heater.—W. J. W.

VIII.—GLASS; CERAMICS.

Gas-fired [glass] furnace; New type of —. M. W. Travers. J. Soc. Glass Tech., 1920, 4, 205–225.

THE grate, fitted with Frisbie underfeed mechanism, is fixed below a conical space which tapers upwards to the "eye," the rate of firing being about 130 lb. of fuel per hr. for a furnace taking eight pots. Secondary air, after passing through a recuperator, enters at the sides of the conical space about 2 ft. 6 in. below the "eye," but owing to the gas and air tending to move up coaxially and combustion only taking place at the interface, little combustion takes place below the sieve. Although the furnace was not worked up to the full capacity, the actual output was over 1 ton of glass worked out for 1 ton of fuel consumed, while after nine months' working the furnace was in excellent condition. A rough estimate of the energy balance-sheet of the furnace shows 56 to 60% of the energy supplied to be utilised in the furnace chamber and lost by radiation and conduction from it.—H. S. H.

Optical glass; Casting of pots for use in experimental work on —. A. B. Taylor. J. Soc. Glass Tech., 1920, 4, 140–150.

A SLIP containing 3 pts. of kaolin, 2 pts. of grog (fired to cone 18 and passed through a 30-mesh sieve) and 0.2% (of the total dry weight) of sodium carbonate and sodium silicate together, was used to cast small experimental pots, 9 ins. in height. The pots lacked uniformity when the slip was poured between the core and the mould, or when introduced under pressure of a head of slip, even when an electric current was passed between the core and the mould. Pots showing a uniform distribution of grog were obtained when the slip entered the base of the mould under an initial pressure of 20–25 lb. per sq. in., which was reduced to 10 lb. per sq. in. after filling until the pot was removed, about 45 mins. later. Only small differences in density exist between a slip which is too thick and one which is too thin; too rapid a rise of slip in the mould leads to the inclusion of air bubbles.

[Glass] pot making; Art of —. C. O. Grafton. J. Amer. Ceram. Soc., 1920, 3, 653–662.

Soda-magnesia glasses; Density of —. S. English and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 153–157.

THE substitution of magnesia for soda diminishes the density of a glass. Winkelmann and Schott's factors of 2.6 for the density of Na₂O, and 3.8 for MgO, would give an opposite result. Tilletson's new factors of 4.1 for CaO and 4.0 for MgO give poor agreement for the glasses examined. Factors of 2.20 for SiO₂, 3.47 for Na₂O, and 3.38 for MgO agree best with the experimental results. The relationship between density and molecular percentage composition is linear for both soda-lime and soda-magnesia glasses.—H. S. H.

Glass tubing; Discoloration produced by lead, antimony, and arsenic in lampworked —. F. W. Hodkin and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 158–161.

THE minimum amount of arsenious and antimony oxides required to be present in the glass to cause discoloration lies between 0.02 and 0.05%, while 0.6% of lead oxide is required. The results are independent of the presence of nitre in the batch, while the presence of manganese dioxide, in amount sufficient normally to act as a decoloriser, does not hinder the appearance of discoloration.

—H. S. H.

Glass; Colouring and thermoluminescence of — produced by radium emanation. S. C. Lind. J. Phys. Chem., 1920, 24, 437—443.

ALL three types of radium rays have the same colouring effect on glass and other materials. The colour is discharged from glass and quartz by heating to 500° C. Violet-coloured glass is slowly decolorised by exposure to sunlight, whilst brown-coloured glass is changed to bright yellow by sunlight or ultra-violet light. Violet-coloured glass heated to 200° C. in the dark luminesces, but the colour is unaffected. Freshly-radiated glass luminesces at temperatures below that of boiling water, whilst glass which has been kept for 2—3 years after radiation only luminesces at 200° C.

—J. F. S.

British fireclays; Composition, drying and firing shrinkage, porosity, and density of — suitable for glass furnace refractory materials. E. M. Firth, F. W. Hodkin, and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 162—205.

THE chemical compositions, the drying and firing shrinkages, porosity, apparent and actual densities of twenty-seven fireclays at a series of temperatures up to 1400° C. are recorded. It is not possible to correlate the physical properties either with the chemical composition of the clays or with their mineral compositions calculated by Washington's method from their chemical analyses (J., 1919, 105A). Little change of shrinkage occurs below 750° C., while usually a sudden expansion occurs at some temperature below 900° C. The variation of porosity with firing temperature is generally greater for highly aluminous clays than for the silicious clays. Clays with more than 2% of fluxes have frequently a wide porosity range and also a marked shrinkage above 750°. The silicious clays are usually easier to work than the aluminous clays. No relation exists between the amount of water required to produce a suitable working consistency of the ground clay and its chemical composition or the size of its particles. Only five of the clays fulfilled the requirements of the Provisional Specification for Glass Works Refractory Materials, one being Grade 1 and four being Grade 3. It would be better to specify a maximum limit for the iron oxide content and then to classify a clay further by its physical properties instead of by its chemical composition.—H. S. H.

Refractory materials; Tensile strength of —. M. W. Travers. J. Soc. Glass Tech., 1920, 4, 138—140.

THE failures of refractory materials in glass furnaces working at high temperatures are not due to the materials being under load, but are caused by the tensile stresses resulting from the shrinkage of supporting blocks. The ideal refractory for withstanding tensile stresses consists of a system of interlocking crystals, formed *in situ*, in a glassy matrix, rather than one consisting of a high percentage of very infusible material with a small quantity of vitreous bond.—H. S. H.

Zirconia-silica; Approximate determination of the melting point diagram of the system —. E. W. Washburn and E. E. Libman. J. Amer. Ceram. Soc., 1920, 3, 634—640.

THE melting points of mixtures of zirconia and silica were determined by heating one end of a small rod, 2 in. long and $\frac{1}{8}$ in. diam., in an oxy-acetylene flame and measuring the temperature of the droplets of fused material with an optical pyrometer. Temperature readings could be duplicated to about 100° C. The melting point of pure zirconia is about 2700° C.; that of natural zircon and of a mixture of zirconia and silica in molecular

proportions is about 2300° C. An eutectic between ZrO_2 and $ZrSiO_4$ occurs near 2300° C. For use as a refractory up to 2550° C. the presence of silica as an impurity in zirconia is not necessarily detrimental since the fluxing action can be eliminated by increasing the silica content to 33%. It is probable that refractories of considerable strength might be manufactured from zirconia bonded with zirconium hydroxide and precipitated silica in molecular proportions. Iron may be completely removed from zirconia by heating it at 300° C. in a current of phosgene. (Cf. J. Chem. Soc., Oct.)—A. B. S.

Graphite-ash and bond clays; Fusibility of mixtures of —. R. N. Long. J. Amer. Ceram. Soc., 1920, 3, 626—633.

THE ash from Alabama graphite has a higher fusion point than that from Ceylon graphite and is less active as a flux in mixtures of clay and ash. No formation of an eutectic could be detected in mixtures of graphite ash and bond clay. Graphites with a higher percentage of ash than those now in use might be employed with the more refractory clays without serious reduction in refractoriness.

—A. B. S.

Clays; Ultramicroscopic examination of some —. J. Alexander. J. Amer. Ceram. Soc., 1920, 3, 612—625.

FOURTEEN samples of clay were mixed with water and allowed to settle for 9 mins., and the supernatant fluids examined with an ultramicroscope. English china clay, Florida and North Carolina kaolins, Tennessee ball clay, and Illinois Kaolin Co.'s plastic clay were found to contain many actively colloidal particles, those in the English china clay and Laclede-Christy bond clay 69B being very active, those in Florida kaolin not quite so active, and those in the other clays having only a slow motion. Several of the clays contained iron salts and diffusible products of the hydrolysis of the clays; these coagulants probably balance the protective or deflocculant action of organic substances present. The United States is lacking in primary kaolins such as English china clay and no means are known for converting the abundant secondary kaolins into primary ones of the English china clay type. For some purposes Delaware kaolin, if properly treated, could replace English china clay.

—A. B. S.

Terra-cotta body; Effect of the size of grog in a —. H. E. Davis. J. Amer. Ceram. Soc., 1920, 3, 641—652.

TO develop sufficient strength in both dry and burned terra-cotta, a considerable proportion of fine grog should be used, as coarse grog in the absence of finer grog causes cracking. Fine grog is also a desirable ingredient of terra-cotta which is covered with a slip or engobe, as by its use a close-fitting, smooth-surfaced coating of great weather-resisting power may be obtained. The shrinkage and transverse strength are usually, but not always, increased by increasing the fineness of the grog.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Chromium steels; Some physical constants of —. T. Matushita. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 243—250.

The investigations were carried out on chromium steels containing 0.6% C and up to 20% Cr in the slowly cooled and quickly cooled conditions. The thermal and electrical conductivities decrease to a minimum at 0.6% Cr, then increase to a maximum at 1.2% Cr, afterwards decreasing rapidly to 5% Cr and then slowly. The values for the slowly cooled specimens are always the greater. The variations can be explained from the structure of chromium steel and its change under heat treatment (Murakami, J., 1919, 257 A). In the annealed steels the moduli of elasticity and rigidity increase at first to a maximum, afterwards decreasing to a minimum at about 5% Cr, then increasing again with the higher concentrations of chromium. In the quickly cooled specimens the elastic constants have lower values. Thermal expansion curves are given, the coefficient decreasing with increasing chromium content. The α - β point first decreases to a minimum at 2% Cr, rising again to 5% Cr and afterwards varying little. The expansion coefficient-concentration curves have a minimum at 2% Cr.—T. H. Bu.

Molybdenum steels. G. W. Sargent. Amer. Soc. for Testing Materials, June, 1920. Chem. and Met. Eng., 1920, 22, 1190—1191.

DETAILS are given of a typical basic open-hearth melt in which about 6000 tons of a steel assaying 0.3% C, 0.64 Mn, 0.77% Cr, 0.35% Mo, and 0.12% Si was produced with an average yield of 93% of that calculated. Annealing the oil-quenched steel at progressively higher temperatures decreases the ultimate strength and elastic limit, which are close together, and increases the reduction in area and elongation. Quenching from 2000° F. (about 1090° C.) does not impair the physical properties or cause the characteristic grain growth of overheated steel. Low molybdenum steel (Mo 0.4, Cr 0.9, and C 0.32%) has a martensitic structure which reverts to fine short pearlitic filaments when the steel is drawn at 900°—1000° F. (480°—540° C.); the ferrite coalesces into rounded masses at 1400° F. (760° C.), at which temperature the steel is well annealed and works easily. A steel containing 0.39% C, 1.05% Cr, 0.17% V, and 0.87% Mo on oil quenching from 1600° F. (870° C.) exhibits a pearlitic structure which remains unchanged unless the steel is drawn

above 1400° F. (760° C.) when it is annealed. Thermal studies show that beyond 800° C. a compound is formed in the austenite which, on cooling, dissociates at the normal A₁ point with precipitation of Fe₃C and at 500° C. breaks up into a Mo-Fe compound which further dissociates and eventually on repeated reheatings gives a solid solution of molybdenum in the iron. Molybdenum up to 4% increases the tensile strength and hardness of cast iron.—A. R. P.

Iron-nickel and iron-cobalt alloys; Change of length by magnetisation in —. K. Honda and K. Kido. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 221—232.

The change in length of annealed rods of iron-nickel and iron-cobalt alloys in magnetic fields up to a maximum of 600 gauss was measured and its relation with the constituents of the alloys investigated. The 70% Co alloy shows the largest magnetic elongation of ferromagnetic substances yet investigated.—T. H. Bu.

Magnetic susceptibility; Variation of — during allotropic transformations and melting of some substances. T. Ishiwara. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 233—241.

The magnetic susceptibility of five weakly magnetisable substances (silver bromide, silver chloride, sulphur, zinc, and aluminium) was examined. Generally the susceptibility is constant over the range of temperatures observed, except with zinc, the susceptibility of which decreases one-half in a range of 600° (14°—61° C.). A change of susceptibility is generally found to accompany a change of state, but in the case of silver chloride and bromide such a discontinuity was not observed with the modified torsion balance apparatus used. (Cf. J.C.S., Oct.)—T. H. Bu.

Copper-zinc alloys; Magnetisability of —. R. H. Weber. Ann. Physik, 1920, 62, 666—672.

The magnetic susceptibility of the copper-zinc series was determined and the results plotted against the percentage of copper in the alloy. The compound CuZn₂, which is a greyish-white brittle alloy, has a susceptibility of at least -5.3×10^{-6} , and is, therefore, with the exception of bismuth, the most diamagnetic substance so far known.

Copper; Rate of dissolution of metallic — in aqueous ammonia. E. Yamasaki. Sci. Rep. Tôhoku Imp. Univ., 1920, 9, 169—220.

A MORE detailed account of work, the chief results of which have been published previously (J., 1911, 207). (Cf. J.C.S., Oct.)—T. H. Bu.

Brasses; Constitution of certain tin-bearing —. W. Campbell. Amer. Soc. for Testing Materials, June, 1920. Chem. and Met. Eng., 1920, 22, 1191.

INVESTIGATION of the effect of tin on the structure and properties of naval brasses containing 60—65% Cu, 0.5—1.5% Sn, 0—0.5% Fe, 0—1.0% Pb, 0.5% Al, and Zn remainder showed that the amount of tin which will cause the alloy to change from the ductile "naval brass" type to the less desirable "gun-metal" type is inversely proportional to the amount of copper present, decreasing from 2% Sn with 56.5% Cu to 0.5% Sn with 67% Cu.—A. R. P.

Bronzes; Composition of ancient Eastern —. M. Chikashige. Chem. Soc. Trans., 1920, 117, 917—922.

ANCIENT Chinese and Korean bronze mirrors are of four types according to their surface colours, viz., white, pale yellow, deep yellow, and red. The percentages of tin become less and less in the above order and correspond with the chronological period of the mirrors. The white bronzes contain on the

average 67% Cu, 27% Sn, and 6% Pb. The alloy corresponds with the ϵ phase in the Cu—Sn diagram, and the lead lies between the granules of the solid solution of these two metals and acts as a cement. Ancient bronze weapons excavated in China and Japan contain 10–20% Sn, together with 4–8% Sb and sometimes appreciable quantities of iron and nickel, and in some cases even lead up to 8 or 9% was found. Ancient Chinese coins generally contain less tin with much lead, so that some of them can scarcely be termed bronze. For instance, coins current during the eighth to the sixth centuries B.C. gave on analysis the following figures:—Bell money, 67.5% Cu, 16.5% Sn, 10.8% Pb, 1.8% Sb, 2.3% As, and 0.9% Ni, and knife money 46.2% Cu, 9.2% Sn, 43.5% Pb, 0.7% Fe, and 0.3% Ag.—G. F. M.

Corrosion [of bronzes and brasses]; Tests for relative —. B. Feuer. Chem. and Met. Eng., 1920, 22, 1197–1198.

THE action of dilute solutions of salts commonly found in water on brass and bronze was examined by plotting the potential fall between the surface of the metal and the solution in which it is immersed as measured by the aid of an auxiliary calomel electrode. The results obtained with ten different alloys in a $N/10$ solution of potassium nitrate are shown in a graph in which current values are plotted against the logarithms of the potential values. The results check those obtained by means of the "ferroxyl" indicator (Walker and others, J., 1907, 1051).—A. R. P.

Zinc alloys; Pyrophoric — and their utilisation. J. Czochralski and E. Lohrke. Z. Metallk., 1920, 12, 145–149. Chem. Zentr., 1920, 91, IV., 252. (Cf. Guertler, J., 1920, 67 A.)

DIFFERENT refining methods for the removal of aluminium from these alloys (Zn with 3% Al and 6% Cu) are discussed. Melting with sodium nitrate and a flux (sodium chloride and potassium carbonate) seems practicable, the aluminium being reduced to traces. In experiments made with perchlorate instead of nitrate, with addition of potassium carbonate and sodium chloride, even more satisfactory results were obtained. By mixing with zinc oxide and chloride and calcium chloride the aluminium can be removed fairly satisfactorily, but a dense fume of aluminium chloride is formed which tends to stop up the flues.—T. H. Bu.

Bearing metals containing calcium. Hart. Metall. Techn., 1920, 46, 73. Chem.-Zeit., 1920, 44, Rep., 220.

BEARING metal containing calcium instead of tin has a yield point (2000 kg. per sq. cm.) $2\frac{1}{2}$ times as high as that of the tin alloy, a m.p. 120° – 200° C. higher (370° C.), and a Brinell hardness number of 35–45. The calcium forms a compound with the lead which is soluble in molten lead, and which crystallises out on cooling in a similar crystalline form to lead. The solid alloy consists of hard crystals of the calcium-lead compound embedded in a softer ground mass of mixed crystals of lead and other metals. Clean iron crucibles are most satisfactory for melting the alloy, and the charge should be poured at about 450° – 480° C. If it is to be used in layers less than 18 mm. thick the metal to which the coating is to be applied should be first tinned, then heated to such a temperature that on pouring the alloy the tin acts as a solder between the metal base and the alloy.—A. R. P.

Aluminium; Electromotive behaviour of —. I. A. Smits. Proc. K. Akad. Wetensch. Amsterdam, 1920, 22, 876–881.

THE valve action of aluminium in the conversion

of alternating current to direct current is explained as follows. On anodic polarisation a small quantity of oxygen is absorbed; this maintains the surface layer of the aluminium in a state of internal strain in which the metal layer behaves as a non-metal and has a high resistance; a film of oxide may form under certain circumstances and also has a high resistance. On reversing the current the oxygen is removed by the liberated hydrogen and the surface of the metal returns to its internal equilibrium and becomes thereby a good conductor. There is no oxide film on ordinary clean aluminium. (Cf. J.C.S., Oct.)—J. F. S.

Alloys of iron-carbon (steels), copper-tin (tin bronzes), copper-zinc (brasses), and copper-aluminium (aluminium bronzes); Similarity in micrographic appearance existing at different states between —. A. Portevin. Comptes rend., 1920, 171, 350–353.

THE author has obtained photomicrographs for copper-zinc alloys showing first the eutectoid resolved during cooling and, secondly, the martensitic state. Thus the austenitic, martensitic, and troostitic states and the two aspects of the eutectoid have now been observed for steels, brasses, tin bronzes, copper, and aluminium bronzes.—W. G.

Thermoelectric power of pure metals. H. Pélabon. Ann. Phys., 1920, 13, 169–187.

THE thermoelectric power of pure metals varies continuously with the temperature, there being no discontinuity at the m.p. For the metals in the liquid state the thermoelectric power is a linear function of the temperature in the case of lead, tin, and bismuth. With antimony the results are not so regular.—W. G.

Molybdate: its occurrence, detection, and determination in partly oxidised molybdenite ores. J. P. Bonardi. Chem. and Met. Eng., 1920, 23, 205–206.

MOLYBDITE ($\text{Fe}_2\text{O}_3, 3\text{MoO}_3, 7\frac{1}{2}\text{H}_2\text{O}$), which commonly accompanies molybdenite, is not amenable to concentration by flotation; hence serious losses of molybdenum may occur when using this method of concentration with ores containing molybdate. The presence of this mineral may be detected by leaching the ore with a boiling 10% solution of ammonia, sodium carbonate, or hydrochloric acid. The solution is filtered, after having been made ammoniacal if acid was used, the filtrate acidified with hydrochloric acid, and thiocyanate added, followed by zinc. A bright cherry-red colour, which is extracted when shaken with ether, shows the presence of molybdate. To determine the molybdenum present in the oxidised form 5–10 g. of finely ground ore is extracted as above, the solution, if alkaline, acidified with hydrochloric acid, treated with a little hydrogen peroxide, then with an excess of ammonia, boiled, and filtered. The filtrate is acidified with hydrochloric acid, 5–10 g. of ammonium acetate added, and the liquid titrated with a standard solution of lead acetate. A slight excess of the acetate is eventually added and the precipitate filtered off, ignited, and weighed as lead molybdate.—A. R. P.

Copper; Extraction of — from slags and residues. Ostermann & Flüs. G.P. 309,160, 12.6.17.

THE slag etc. containing copper is added as a flux to the charge of a coke-gas producer from which fluid slag is withdrawn. The last traces of copper compounds are reduced and the copper obtained in fluid form.—T. H. Bu.

Copper-coated iron and other metals; Process for separating copper from —. Hirsch, Kupfer- und Messingwerke A.-G., and L. von Grothaus. G.P. 321,525, 15.11.18.

THE material is packed in layers in calcium sulphide contained in iron boxes and heated at a high tem-

perature. The layer of cuprous sulphide formed is easily detached from the metal.—T. H. Bu.

Smelting-furnace. R. G. Ward, Assr. to Independent Mines Smelting Co. U.S.P. 1,318,525, 3.8.20. Appl., 19.6.18.

THE furnace consists of an upper charging chamber and a lower combustion chamber with a horizontal hearth interposed between. This hearth consists of an annular, transversely-curved, charge-supporting metal surface forming a hearth wall with a narrow inner zone tangential to a line which coincides with the normal angle of repose of the material on the hearth.—J. W. D.

Metal alloy of great hardness for tools, especially drawing dies. Ges. für Wolframindustrie m.b.H. G.P. 320,996, 3.4.18. Addn. to 310,011 (J., 1920, 30 A).

A SMALL proportion of chromium (as ferrochrome) is introduced into the alloy of the principal patent. An alloy for borers contains W, Fe, Cr, Ti, Cu, and Co.—T. H. Bu.

Steel; Manufacture of —. R. A. Hadfield. U.S.P. 1,317,711, 27.7.20. Appl., 10.8.17. Renewed 27.5.20.

SEE E.P. 127,302 of 1917; J., 1919, 503 A.

Furnace for heating metal articles and the like. W. H. Southorne. U.S.P. 1,317,719, 27.7.20. Appl., 27.12.18.

XII.—FATS; OILS; WAXES.

Stearine industry; Practical methods used in the —. Knor. *Seifensied.-Zeit.*, 1920, 47, 105, 164, 192, 261. *Chem.-Zeit.*, 1920, 44, Rep., 215.

Oils and fats for use in the stearine industry are stored in well-ventilated buildings with blue glass windows. They are purified by washing with sulphuric acid (sp. gr. 1.16) and deodorised by blowing with compressed air after heating *in vacuo* at 115° C. The fat is thoroughly washed, heated at 105° C. to remove water, and then hydrolysed in an autoclave by means of steam at 11–12 atm., in the presence of 3% of lime, 1–1.5% magnesia, 1% of zinc oxide, or 0.5% of zinc dust, preferably a mixture of 0.5 ZnO and 0.5 Zn. For "black" fats magnesia is the best and zinc dust for fats which are not to be distilled. Fish fats and vegetable tallows require the addition of more of the hydrolytic agents and a higher pressure. After completion of the hydrolysis (8–10 hrs.) the steam valve is opened and the mixture allowed to stand for 2 hrs. for the glycerin water to separate, and the two layers are then expelled from the autoclave. The soap present is decomposed by running the fatty acids into boiling sulphuric acid (sp. gr. 1.16). The glycerin water has normally a sp. gr. up to 1.0325.—C. A. M.

Tristearin; Anomalies in the solidification point of —. B. H. Nicolet. *J. Ind. Eng. Chem.*, 1920, 12, 741–743.

TRISTEARIN apparently exists in two modifications melting respectively at about 71.6°–72.2° C. and 55° C. Notwithstanding the rapidity with which the unstable form is converted into the stable form of higher m. pt. when heated, the solidif. pt. usually given for tristearin is about 56° C., i.e., that of the unstable form. By "seeding" liquid tristearin with the stable modification above 60° C. solidification takes place without the formation of the unstable modification, but the latter always appears to be formed when the "seeding" with the stable modification is effected below 56° C. A necessary condition for the phenomenon of double solidif. pt. is that the solidification of the unstable form shall raise the temperature sufficiently to reach the temperature of transition to the stable form. Analogous results were obtained with completely hydrogenated soya bean oil, but not with hydrogenated linseed oil and cottonseed oil. (Cf. *J.C.S.*, Oct.) —C. A. M.

Sulphonated oils; Determination of sulphate in —. E. J. Kern. *J. Ind. Eng. Chem.*, 1920, 12, 785.

UNCOMBINED sulphate in sulphonated oils may be determined by shaking 20–40 g. of the oil with 100 c.c. of 10% monosodium phosphate solution, filtering the aqueous extract, acidifying 50 c.c. of the filtrate, and precipitating the sulphuric acid with barium chloride. The extraction is as complete as after 3 extractions with brine and ether. The method may also be used for the separation of the total sulphate after decomposing the sulphonated oil by boiling with hydrochloric acid. A preferable method is to evaporate the oil with sodium carbonate, ignite and fuse the residue, boil the solution of the fused mass with sodium peroxide, and precipitate the sulphuric acid from the acidified liquid.—C. A. M.

Polenske and Reichert-Meissl values; Effect of pressure on the —. V. H. Kirkham. *Analyst*, 1920, 45, 293–297.

THE Polenske value of a fat is a function of the pressure, and unless values are corrected to normal pressure they may be untrustworthy. For instance, a Polenske value of 2.68 at 760 mm. falls to 2.06 when the determination is made at a pressure

of 627 mm. For butter fat the relationship between pressure and the Polenske value is shown by the formula, $V = r(P - k)/(p - K)$ where P = pressure at which the Polenske value is V ; p = pressure at which the Polenske value is r , and K = a constant, or pressure at which the Polenske value is zero, in this case 45 mm. Therefore the value corrected to normal pressure is

$$\frac{\text{observed Polenske} \times (760 - 45)}{(\text{barometric pressure} - 45)}.$$

The Reichert-Meissl value is a logarithmic function of the pressure, and the errors introduced by ordinary variations in the atmospheric pressure are quite small.—W. P. S.

PATENTS.

Oil presses; Press-plate for cotton-seed and other —. N. B. Henry. Assr. to The Murray Co. U.S.P. 1,348,004, 27.7.20. Appl., 9.9.19.

Oil-press. M. B. Green. U.S.P. 1,348,870, 10.8.20. Appl., 6.3.20.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Paints; Instrument for measuring the hiding power of —. R. L. Hallett. Amer. Soc. for Testing Materials, June, 1920. *Chem. and Met. Eng.*, 1920, 22, 1192.

THE instrument consists of a long microscope tube with a plane ground glass objective and a small hole in place of the eye-piece. If a card having a contrasting stripe painted on it is placed under the objective and gradually withdrawn vertically, the distance at which the field, by diffusion, appears uniformly illuminated is proportional to the contrast existing on the card. The objective is prepared by polishing back an overground piece of plane glass until a white card with a black stripe becomes merged under view at a distance of about 15 cm. The instrument is calibrated by viewing various greys from pure white to dark black, each shade having previously been analysed for white and black by a Howland colour photometer. A logarithmic curve is then constructed with objective distances as ordinates and per cent. hiding power as abscissæ.—A. R. P.

Shellac, shellac varnish, and lacquer; Rapid examination of —. T. L. Crossley. *J. Ind. Eng. Chem.*, 1920, 12, 778–781.

THREE samples of shellac of different grades contained 28.7–31.8% (av. 30.1%) of constituents soluble in ether, and 70.0–70.2% insoluble, the discrepancy being attributed to oxidation. A sample of stick-lac contained:—Woody matter, fibre, etc., 8.5; gums insol. in ether, 70.7; and gums sol. in ether, 25.0%. Assuming shellac to contain 70% insol. in ether, four samples of shellac rosin varnish, specified to contain 75% shellac, were found to contain from 40 to 77%, and these results were subsequently confirmed. From 5 to 7 g. of varnish is stirred with 50–60 c.c. of ether, the solution decanted through a filter, and the insoluble residue washed with successive portions of ether (20 c.c.) until colourless, dried on the water bath, and finally at 110°–120° C. and weighed. Any deposit forming in the filtrate is separated, washed, dried, and added to the insoluble residue, the clear solution is evaporated and the residue dried and weighed as above. The total gums are obtained by evaporating 5–10 g. of the varnish. In testing shellac gum the sample is ground to pass a 30-mesh sieve, and 1 g. moistened with 5 c.c. of alcohol before the treatment with ether. In the case of varnishes containing linseed oil care must be taken to prevent oxidation of the oil during the evaporation of the alcohol.—C. A. M.

PATENTS.

Titanium; Compound of — and process for the manufacture of same. V. M. Goldschmidt, Assr. to Titan Co. A/S. U.S.P. 1,318,129, 27.7.20. Appl., 12.10.17.

A COMPLEX pigment contains a cryptocrystalline titanium oxide, prepared by heating the oxide until the particles exhibit a crystalline interior structure and a smooth exterior surface, mixed with a pigment-forming compound of another element having a different refractive index.—L. A. C.

Paint; Manufacture of a — containing zinc oxide, linseed oil, and zinc oxychloride. E. Wütherich. G.P. 313,031, 21.5.17.

Zinc oxide (100 pts.) is ground with 70 pts. of linseed oil, and 50 pts. of chemically pure 20% hydrochloric acid is added to the mixture. The paint dries in a few hours giving a hard and durable surface which does not peel.—L. A. C.

Impregnating material composed of oil or varnish for the fibrous insulating covering of electrical conductors; Production of —. F. Bruggemann. G.P. 315,700, 27.10.16.

Drying of the impregnating material due to oxidation of the oil or varnish is prevented by the addition of a reducing agent such as zinc dust at ordinary temperature.—J. S. G. T.

Acid resins from the manufacture of benzene; Preparation of pale, readily-drying oils from —. J. Schümmer. G.P. 320,255, 7.5.18.

Acid resins from the manufacture of benzene are distilled *in vacuo*, the sulphurous acid fumes being recovered and converted into sulphuric acid.—C. A. M.

Resinous material; Production of a — from wood tar. J. D. Riedel A.-G. G.P. 320,620, 11.7.18.

Wood tar is heated and agitated in the presence of a liquid, gaseous, or nascent halogen, with or without the addition of a catalyst, until a cooled sample solidifies to a brittle resinous mass. The product is as brittle as shellac, and dissolves in alcohol, giving a rapidly drying varnish.—L. A. C.

Varnishes and paint media; Preparation of anti-septic and preservative —. Chem. Fabr. Flörsheim H. Noerdlinger. G.P. 320,656, 16.4.16.

Tar from coniferous woods is freed from constituents boiling below 200° C. by distillation, which may be carried out in a current of air or steam under reduced pressure, and the residue is hardened or converted into driers by any suitable method and dissolved in a varnish solvent.—C. A. M.

Linoleum; Manufacture of floor-covering as substitute for —. J. H. P. Ligterink. U.S.P. 1,348,571, 3.8.20. Appl., 23.11.18.

SEE E.P. 133,481 of 1918; J., 1919, 916A.

Bronze powder. U.S.P. 1,347,927-S. See X.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber micro-fungus. J. Scott. Indianrubber J., 1920, 60, 410—412.

VULCANISED rubbers, particularly the purer more elastic grades, when exposed to moist air are liable to the development of growths of the micro-fungus, *Stemphylium microsporoides*; to the naked eye the growth often resembles dust, but the fungus threads penetrate the surface rubber and may cause disintegration; rubber injured in this way wrinkles in a curious manner and may become very weak.—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome tanning; Single bath —. E. Griliches. Z. Elektrochem., 1920, 26, 312—354.

THE experiments were performed by rotating pieces of calf skin in the requisite solution during 24 hrs. at the ordinary temperature. With chromium sulphate solutions of differing acidity, that component which is in excess in the solution is more readily absorbed at the commencement of tanning; in concentrated violet solutions the more basic, in more dilute solutions the more acidic component is absorbed, whilst in green solutions a more acidic substance is absorbed than in the violet solutions. From feebly basic solutions a more acidic portion is initially absorbed, whilst strongly basic solutions yield a basic component. As soon as the skin is saturated with one component it commences the more strongly to absorb the other. Apparently the skin does not in general possess the ability of absorbing both components equally; only in strongly basic solutions are the variations in acidity comparatively slight. If during the first hours the absorbed salt is more acidic than that contained in the original solution, the total salt absorbed is also more acidic than the solution and conversely. When washed, the leather appears to retain the chromium component much more firmly than the acidic portion. Tanning can be effected by either green or violet chromium solutions, but although the rate of absorption of chromium oxide and the amount of oxide absorbed are approximately the same from either solution, a much greater amount of acid is absorbed from the green solution corresponding thus to the higher degree of hydrolysis.—H. W.

PATENTS.

Bating hides; Processes based on the action of enzymes for — and baths, mixtures, and the like for use therein. F. Rampichini & Co. E.P. 124,718, 24.2.19. Conv., 23.3.18.

ANIMAL glands containing one or more enzymes suitable for emulsifying fats or peptonising albuminoid substances are mixed with rock salt, the mixture triturated, dried at about 40° C. and then added to a solution of salicylic acid (0.5—1 per 1000), phenol, benzonaphthol, arsenious anhydride, or other antiseptic substance which does not damage the tissue of the hide, or hinder the action of the enzymes but prevents fermentative or foreign biochemical action. A substance adapted to eliminate the insoluble calcium salts in the hide is also added to the solution, which can be used for bating.—D. W.

Waste liquors of the hide-treating art; Recovery of proteids from —. C. L. Peck, Assr. to The Dorr Co. U.S.P. (a) 1,347,822 and (b) 1,347,823, 27.7.20. Appl., 20.7.18 and 6.1.20.

THE liquors are separated into lime sludge and an effluent, the proteids in which are precipitated by mixing them with the effluent from waste tanning liquors. The proteid sludge is heated with (a) sodium hydroxide or (b) lime sludge, dried and used as a fertiliser.—D. W.

Leather; Preparation of a substitute for sole —. Von Heynitz. G.P. 320,629, 7.11.17.

BARK of birch is saturated with a solution which fills the pores and renders it waterproof without affecting its flexibility. Suitable solutions are glue which has been treated with potassium chromate or gallotannic acid, or viscose or acetylcellulose solution.—C. A. M.

Cascien solution; Stable — and process of making same. H. V. Danham. U.S.P. 1,317,845, 27.7.20. Appl., 25.3.19.

Boric acid is dissolved in hydrofluoric acid solu-

tion, alkali added to form the salt, then casein added, and the whole agitated and heated.—D. W.

Skin-like [algin] compounds; Method of forming shaped articles from precipitated —. C. E. Swett, Assr. to A. D. Little, Inc. U.S.P. 1,318,459, 3.8.20. Appl., 27.3.19.

A porous form is wetted with an aqueous solution which will precipitate an algin compound from an alkaline solution of an alginate, then a solution of alkaline alginate is applied to the wetted form, and subsequently the algin compound is removed from the form.—D. W.

Tanning. C. V. Greenwood. U.S.P. 1,349,150, 10.8.20. Appl., 28.7.15.

SEE E.P. 7635 of 1915; J., 1916, 748.

Hides and skins; Machine for treating —. D. Mercier. U.S.P. 1,347,866, 27.7.20. Appl., 30.12.19.

Basic sulphate of chrome. E.P. 148,615. See VII.

XVI.—SOILS; FERTILISERS.

Reaction of the soil; Examination of the factors which determine the —. I. Determination of the acid or basic properties of a soil. II. Reaction of liquids which are saturated with calcium carbonate. N. Bjerrum and J. K. Gjaldback. Kong. Vet.- og Landbohøjskole Aarskrift, 1919, 48–91. Chem. Zentr., 1920, 91, IV., 125.

The reaction of a soil is represented best by the hydrogen ion concentration, determined in the soil solution or in a soil extract prepared in a definite manner. It is best to determine the amount of acids or bases which must be added to the soil to maintain a definite reaction. A series of such results can be obtained by means of electrometric titration, and can be plotted as a titration curve. From the law of mass action it follows that the hydrogen ion concentration in a liquid saturated with calcium carbonate is expressed by the relation between the calcium ion concentration and the carbon dioxide pressure, thus:

$$C_H = K \cdot \sqrt{C_{Ca} \cdot P_{CO_2}}$$

By electrometric measurements the value of $\log K$ at 18° C. was determined to be -5.2 . Although a soil may contain calcium carbonate, it may still react acid. The more carbon dioxide there is in the soil-air and the more lime there is in the soil solution, the more acid will be the reaction of the soil.—J. H. J.

Chemosynthesis at denitrification with sulphur as a source of energy. M. W. Beijerinck. Proc. K. Akad. Wetensch. Amsterdam, 1920, 22, 890–908.

SOME of the common denitrifying bacteria such as *B. denitrificans* and *B. Stutzeri* may occur in two physiologically different modifications, which are hereditarily constant when their feeding conditions remain constant. The autotrophic form is adapted to an inorganic medium (sulphur or thiosulphate-chalk-nitrate) and shows chemosynthesis; the heterotrophic form requires organic food. They may be compared with the oligotrophic and the polytrophic conditions of the nitrifying organisms. Intermediate forms are known, and autotrophy may be gradually lost, but the heterotrophic form preserves the power of denitrification with organic food. The organisms which produce nitrites from ammonium salts are also related to hereditary modifications with the character of saprophytes, living on organic food and unable to oxidise ammonium salts.—J. F. S.

Plants; Absorption and assimilation of food materials by —. E. Reinau. Z. Elektrochem., 1920, 26, 329–342.

CORRESPONDING with the recent theory of the assimilation of carbon dioxide by plants, a similar hypothesis is proposed for other elementary food materials, and conclusions are drawn therefrom for the complete metabolism of plants. The individual character of each metabolic process and the interlocking of the various processes and their effect on manuring are considered. (Cf. J.C.S., Sept.)—H. W.

Copper spray liquids. Villedieu and Villedieu. See XIXb.

XVII.—SUGARS; STARCHES; GUMS.

Sucrose; Double polarisation method for the estimation of —; and the evaluation of the Clerget divisor. R. F. Jackson and C. L. Gillis. Sci. Paper, No. 375. Bureau of Standards, 126–194.

THE rate of decomposition of invert sugar in the presence of 5 c.c. of 38.8% hydrochloric acid at different temperatures is indicated by the following decrease of rotation (in degrees on sugar scale) per min.: 80° C., 0.167; 70° 0.056; 60° 0.0132; and

50°, 0.0034. Under the conditions of the Herzfeld procedure (*cf.* J., 1920, 379A), the maximum *levo*-rotation is reached in a total time of 5½ min., and during the remaining period of heating specified (2 to 4½ min.) decomposition of the levulose occurs to such an extent as to render reproducibility by different operators difficult if not impossible. Constant results are obtainable when hydrolysis is carried out at 60° C. during a total period of 9 min., using the same amount of hydrochloric acid, preferably diluted with an equal volume of water previous to addition. On determining the divisor *d* required for the calculation of the sucrose α in the formula: $100 P = P'/d$, in which *P* and *P'* are the direct and invert polarisations respectively, the value 133.25 for a concentration of 13 g. of inverted sucrose at 20° C. was established. That this value is correct, and that Herzfeld's factor 132.66 is inaccurate was confirmed by inverting with invertase and adding the usual amount of hydrochloric acid before making the solution up to 100 c.c. To avoid error due to the presence of invert sugar, the rotation of which in the strongly acid solution used for inversion is different to that of the approximately neutral solution used for the direct reading, it is proposed in the case of cane products having a high content of reducing sugars to add to the liquid used for the direct reading 2.315 g. of sodium chloride, which produces the same effect upon invert sugar as 10 c.c. of 6.34 *N* hydrochloric acid (*i.e.*, 5 c.c. of 38.8% acid diluted with an equal volume of water). Another source of error is the presence of amino compounds, the rotation of which is strongly influenced by the presence of hydrochloric acid. This is avoided by neutralising the inverted solution with sodium hydroxide or ammonia before completing to volume, preferably with ammonia, as a slight excess is without influence on the levulose. The rotation of sucrose instead of being 100 becomes 100—0.265*m* in presence of sodium chloride, and 100—0.169*m* in that of ammonium chloride; while the effect on the invert polarisation is shown by the values:—32.00—0.540*m* for sodium chloride, and —32.00—0.563*m* for ammonium chloride, in which *m* is the grms. of salt present in 100 c.c., and —32.00 is the rotation at 20° C. produced by the hydrolysis of 13 g. of sucrose by invertase in 100 c.c. without the addition of either hydrochloric acid or salt. In carrying out the method recommended as applicable to all products, a solution of suitable normality is clarified with dry basic lead acetate (Horne's formula, J., 1901, 340), mixed, and filtered; 50 c.c. portions of the filtrate are pipetted into two 100 c.c. flasks. For the direct polarisation, 3.392 g. of ammonium chloride is added, the volume completed at the temperature at which the observations are to be made, and the liquid filtered and polarised. For the invert polarisation, 10 c.c. of hydrochloric acid (sp. gr. 1.1029=6.31 *N*) and 20 c.c. of water are added, and the flask immersed in a water-bath at 60° C. for 9 mins. After cooling rapidly, the volume of ammonia required for exact neutralisation is added from a burette, the temperature is adjusted, the volume completed, the liquid filtered if necessary, and the reading made at a carefully controlled temperature in a double-jacketed tube. In the case of beet products, the inverted solution is neutralised with ammonia as before, but the direct reading is taken in the absence of ammonium chloride; while in that of cane products, 2.315 g. of sodium chloride is added to the solution used for the direct polarisation, but the inverted solution is not neutralised. Tables showing the appropriate divisors for different concentrations of sucrose and different temperatures of observation are given, together with some results of analyses of mixtures showing a very close agreement between the amount of sucrose taken and that found, the average error being about $\pm 0.05\%$.—J. P. O.

Syrup; Cost of manufacture of cane and sorghum table — by the "Norit" process. J. Sauer. La. Planter, 1920, 66, 221—222. Int. Sugar J., 1920, 22, 470—471.

A superior though more costly table syrup is obtained by the following procedure as compared with that generally followed in Louisiana in which the juice coming from the mill is sulphited, heated, and allowed to settle previous to evaporation: The strained juice is mixed with kieselguhr at the rate of about 10 lb. per ton of cane ground, sufficient lime being added only partly to neutralise the natural acidity. After boiling, the juice is filtered, evaporated to sp. gr. 1.25, mixed with the "Norit" decolorising carbon (about 5% on the total solids), heated to 82° C., filtered, and concentrated to about sp. gr. 1.366. The cost of treatment is about 1.57 cents per gallon of finished syrup (kieselguhr being 0.63 cent, "Norit," 0.10, and regeneration, 0.84).—J. P. O.

Decolorising carbon. J. C. Bock. J. Amer. Chem. Soc., 1920, 42, 1564—1569.

"Norit," a vegetable carbon containing 5.13% of ash, when shaken with urine, extracts the whole of the uric acid, a large amount of the urea, creatinine, total nitrogen, and phosphates, and a small amount of the ammonia-nitrogen, chlorides, and dextrose. Bouillon cultures after a few seconds shaking with "norit" show a marked decrease in the bacteria content. The adsorption of a pure substance is always much greater than from a mixture. Lactose is readily adsorbed from diluted milk. In all cases the adsorption is better with washed "norit" (ash 2.18%) than with the commercial preparation.—J. F. S.

Dextrose; Action of hydrogen cyanide on —. Kiliani's reaction. J. Bougault and J. Perrier. J. Pharm. Chim., 1920, 22, 129—138.

THE transformation of hexoses into acids containing one carbon atom more in the molecule, by the action of cyanides, does not take place in acid solutions, a concentration of *N*/100 hydrochloric acid being sufficient to prevent it; it appears to be catalysed by minute quantities of alkalis. The reaction between dextrose and potassium cyanide is bimolecular. In a solution containing 1% of dextrose and 3 or more molecular equivalents of potassium cyanide the sugar is completely transformed in 2 days at 20° C. or in 3 days at 15° C.; and by employing a known quantity of cyanide and determining the excess the reaction might be used for estimating dextrose, galactose, etc. The transformation products from dextrose have $[\alpha]_D^{20} = +1.87^\circ$ so that the change of rotation might be used to determine dextrose provided a sufficient excess of cyanide is used and other reactive sugars are absent. Sucrose is affected by potassium cyanide to only a very slight extent. In a solution containing about 2% of potassium cyanide and about 40% of reducing sugar the cyanide is completely decomposed within 10 hrs.—J. H. L.

Polysaccharides; Hydrolysis of —. E. Hildt. Bull. Soc. Chim., 1920, 27, 690—695.

A STUDY of the hydrolysis of sucrose, raffinose, and inulin by a mixture of 2 mols. of sodium benzenesulphonate and 1 mol. of sulphuric acid. This catalyst does not affect the optical or reducing properties of dextrose or galactose even after 8—10 hrs. at 95°—98° C. The rotatory power but not the reducing power of levulose diminishes under such conditions. The non-levulose sugars are not hydrolysed at the ordinary temperature, whereas in the case of sucrose, raffinose, or inulin the formation of levulose is completed at 13°—15° C. after sufficient time.—W. G.

Crystallisable sugar and free acids in plants. H. Colin. *Comptes rend.*, 1920, 171, 316—318.

THE existence of sucrose in a number of fruits in the presence of free acid at a concentration more than sufficient to cause its inversion is shown to be due to the presence of alkali salts of the organic acids in the juices, which lessen the hydrolysing action of the free acids.—W. G.

Potassium salts from molasses. Von Stietz. *See* VII.

PATENTS.

Rice starch; Process for the manufacture of —. Reckitt and Sons, Ltd., and C. H. Hardy. E.P. 147,255, 7.5.19.

RICE grains are steeped in water for a few hours and then ground until 98% passes a 130×130-mesh silk sieve, water being added during the grinding so that the resulting paste shall contain 60—62% of water. The paste is further diluted to 18°—25° Tw. (sp. gr. 1.09—1.125) and the starch separated in a centrifuge, or the paste is diluted to 1.5°—2° Tw. (sp. gr. 1.007—1.01) and the separation made by decantation. The non-starchy substances may be collected and used as fodder.—W. P. S.

Sugar; Process of extracting —. L. Naudet. U.S.P. 1,343,737, 15.6.20. Appl., 24.5.16.

See F.P. 466,590 of 1913; J., 1914, 878.

XVIII.—FERMENTATION INDUSTRIES.

Capillary active substances; Titrations with — as indicators. IV. *Buffer systems in wort and beer.* W. Windisch and W. Dietrich. *Woch. Brau.*, 1920, 37, 255—257, 261—264. (Cf. J., 1920, 128 A, 461 A, 524 A, 607 A, 613 A.)

THE surface tension of wort or beer is in general slightly lowered by addition of N/10 alkali or N/10 acid. It is lowered also both by sodium undecylate and by eucupine dihydrochloride. The changes of surface tension in the course of titration with N/10 alkali and N/10 acid, in presence of the indicators mentioned, indicate in wort an equilibrium between organic acids and their salts and primary and secondary phosphates. During fermentation the system becomes more acid; bicarbonates appear and secondary phosphates disappear.—J. H. L.

Yeast-like fungi; Action of ultra-violet light on —. B. Feuer and F. W. Tanner. *J. Ind. Eng. Chem.*, 1920, 12, 740—741.

OLD cultivations of 30 different kinds of yeast-like fungi were distributed in water in Petri dishes and exposed to ultra-violet light from a R.U.V. quartz mercury vapour lamp (operating on 110 volts) at a distance of 25 cm. Twenty-three of the organisms were killed within 1 min., only 2 survived 7 mins., and one (*Torula monosa*) 10 mins.—C. A. M.

Saccharase [invertase]; Preparation of highly active —. III. *Purification by dialysis.* H. von Euler and O. Svanberg. *Z. physiol. Chem.*, 1920, 119, 175—190.

SEVERAL of the authors' invertase F-preparations (cf. J., 1910, 1324) were submitted to fractional dialysis through a collodion membrane. It was found that the carbohydrate content of the enzyme rose as the dialysis went on until a point was reached when it became stationary. The authors conclude that invertase must consist chiefly of carbohydrates. The nitrogen content of the dialysed invertase, on the other hand, diminished, and

reached a limit rather higher than the one obtained by one of the authors in a previous investigation. These experiments show that invertase does not require a co-enzyme for its function.—S. S. Z.

Saccharase [invertase] preparations; Diffusion experiments with highly active —. H. von Euler, A. Hedelius, and O. Svanberg. *Z. physiol. Chem.*, 1920, 110, 190—217.

DIFFUSION experiments with different invertase preparations have shown velocities of diffusion of varying magnitudes, and consequently the molecular weights calculated from these figures also showed significant variations. From the results obtained, which are given in detail, the authors conclude that the substrate and the products of the enzymic action do not diminish the size of the colloidal particles of the invertase. Neither is the velocity of diffusion influenced by the optimum acidity which is required for the action of the enzyme as compared with the reaction of pure water.—S. S. Z.

Enzymes of B. coli communis which are concerned in the decomposition of glucose and mannitol. IV. *Fermentation of glucose in the presence of formic acid.* E. C. Grey. *Proc. Roy. Soc.*, 1920, B, 91, 294—305.

THE products of the breaking down of dextrose by *B. coli communis* may be divided into three groups, namely: lactic acid; acetic acid, alcohol, and succinic acid; and formic acid, carbon dioxide, and hydrogen, the second and third groups being closely related. The presence of formic acid as calcium formate does not inhibit the formation of formic acid, and the consequent production of carbon dioxide and hydrogen in the fermentation of dextrose by *B. coli communis*. (Cf. J.C.S., Oct.) —W. G.

Enzyme action in Echinodontium tinctorium, Ellis and Everhart [a wood-destroying fungus]. H. Schmitz. *J. Gen. Physiol.*, 1920, 2, 613—616.

THE presence of esterase, maltase, lactase, sucrose, raffinase, diastase, inulase, cellulase, hemicellulase, urase, reumet, and catalase has been detected in *Echinodontium tinctorium*, Ellis and Everhart, a wood-destroying fungus widely distributed in Western America.—H. W.

Fermentation tube [for sugars etc.]; Modified form of the Smith —. A. V. Fuller. *J. Ind. Eng. Chem.*, 1920, 12, 595.

THE bulb of the fermentation tube, instead of being symmetrical, is trough-shaped on its under side in order to facilitate the falling of the growth to the lowermost portion of the gas tube proper; the gas, as it is liberated, rises vertically and is trapped without appreciable loss in the bulb. A small quantity of coarse, clean sand placed in the depression aids materially in the disengagement of the gas as it is formed.

—W. P. S.

Fusel oil; Composition of a sample of — and origin of acids in alcoholic fermentation. E. Luce. *J. Pharm. Chim.*, 1920, 22, 136—137.

A SAMPLE of fusel oil, after extraction of phenolic constituents and saponification of esters, was fractionally distilled *in vacuo*, and yielded 3% of pelargonic acid and 9.5% of capric acid, besides a residue consisting probably of normal undecylic and lauric acids. These acids were probably formed

by degradation of higher acids derived from the fatty matters of the yeast.—J. H. L.

Denitrification. Beijerinck. See XVI.

XIXa.—FOODS.

Milk; Micro-organisms persisting in — after pasteurisation: their rôle in the decomposition of hydrogen peroxide. M. Fouassier. *Comptes rend.*, 1920, 171, 327—328.

The organisms, *B. subtilis* and *Tyrophthrix tenuis*, which are frequently found in pasteurised milk, are capable of decomposing hydrogen peroxide in milk, and, if lactic acid-producing organisms are present, abundance of lactic acid is produced. If the latter organisms alone are present they possess very feeble catalysing action on the hydrogen peroxide, but their acid-production is completely inhibited.—W. G.

Gerber's butyrometer; Sulphuric acid unsuitable for use in —. F. Reiss. *Chem.-Zeit.*, 1920, 44, 577.

A stock of sulphuric acid caused trouble when used in Gerber's method for the determination of fat in milk by bursting the butyrometer tubes or blowing out the rubber stoppers. This was due to the presence of a large amount of nitrous acid in the sulphuric acid, oxides of nitrogen being liberated when the acid mixed with the milk in the tube.—W. P. S.

Proteins and methods of determining their composition. A. C. Andersen. *Kong. Vet.-og. Land. Aarskrift*, Copenhagen, 1917, 30—331. *Chem. Zentr.*, 1920, 91, IV., 113.

The Van Slyke method for the analysis of proteins (J., 1911, 1135) is modified, the fifth fraction (amino-nitrogen) being divided into two sub-groups. Glycine, alanine, serine, phenylalanine, tyrosine, valine, and the three isomeric leucines as monoaminomonocarboxylic acids form one sub-group, whilst asparaginic acid and glutamic acid as monoaminodicarboxylic acids form the other. If a mixture of all these amino-acids in solution is neutralised with sodium hydroxide in the way usual for formalin titrations, the monocarboxylic acids, together with proline and oxyproline, remain in the free state whilst the dicarboxylic acids form sodium salts. When the solution is evaporated to dryness and the residue incinerated, the amount of sodium carbonate in the ash is equivalent to the quantity of dicarboxylic acids present.—W. P. S.

Proteins; Relation of the free amino groups to the lysine content in —. K. Felix. *Z. physiol. Chem.*, 1920, 110, 217—229.

The author has estimated the nitrogen titratable with formalin in hydrolysed and non-hydrolysed arachin (from *Arachis hypogaea*), glycinin (from *Sofa hispida*), and gelatin. From the results obtained it is concluded that the fraction of the hydrolysed protein which is precipitated by phosphotungstic acid after the removal of the other diamino-acids contains another nitrogenous substance besides lysine. Van Slyke's assertion that the free amino groups of unhydrolysed proteins contain exactly one half of the nitrogen of the lysine in the protein molecule is not justified.—S. S. Z.

Proteins; Influence of the substrate concentration on the rate of hydrolysis of — by pepsin. J. H. Northrop. *J. Gen. Physiol.*, 1920, 2, 595—611.

The rate of digestion and the conductivity of egg

albumin solutions of different concentrations are approximately proportional at the same pH; this agrees with the hypothesis first expressed by Pauli that the ionised protein is largely or entirely the form which is attacked by the enzyme. (*Cf.* J.C.S., Sept.).—H. W.

Polenske and Retchert-Meissl values. Kirkham. See XII.

PATENTS.

Organic substances; Methods for drying, baking, roasting, and cooking —. G. E. F. Tribes. E.P. 138,101, 21.1.20. Conv., 21.1.19.

DIVIDED organic material, e.g., grains, fruit, coffee, meat, etc., is mixed with a powdered refractory substance so that the surface of the organic material is covered with an air-excluding coating; the mixture is heated to the desired temperature while it is stirred and is then cooled by the further addition of refractory substance, during which addition the stirring is continued.—W. P. S.

Margarine or the like; Manufacture of —. J. R. Sorensen. E.P. 146,567, 18.3.19.

The ingredients are emulsified in an open tank provided with stirrers and a jacket, and are then cooled by circulating cold brine through the jacket.—W. P. S.

Butter substitutes, edible fats, and the like; Manufacture of —. W. Clayton and G. Nodder. E.P. 147,257, 7.4.19.

An emulsion of the required ingredients is passed continuously into one end of a casing containing a hollow rotating worm through which a cooling liquid is circulated. Scraping wheels engage the worm so that the whole of the emulsion is brought in contact with the cooling surface. At the exit end of the casing the material is forced through a fine gauze sieve supported between perforated plates, and then passes through a converging chamber where it is compressed into a compact mass, which is discharged through a nozzle provided with drainage channels for the removal of small amounts of water from the surface of the material. In an alternative apparatus the emulsion is pumped successively through a cooling chamber, a chamber of gradually increasing diameter, a sieve, a converging chamber, and a nozzle fitted with drainage channels. The material may be acted on by beaters or stirrers before and after passing the sieve.—W. P. S.

Bread; Manufacture of leavened —. H. A. Kohman and R. Irvin. U.S.P. 1,345,680, 6.7.20, Appl., 13.12.19.

LAXOLIN is mixed with the dough as a shortening agent.—W. P. S.

Coconut; Process of preparing or treating — and product obtained thereby. F. Baker, jun. U.S.P. (a) 1,318,687, (b) 1,318,688, and (c) 1,348,689, 3.8.20. Appl., (a) 31.10.17, (b, c) 14.10.18.

(A) FINELY-DIVIDED coconut kernel is heated at 212°—225° F. (100°—107° C.) in open receptacles, and the latter, while hot, are transferred to a chamber from which the air is then exhausted. The receptacles are closed while *in vacuo*, heated to a temperature sufficient to sterilise the contents, and then cooled suddenly. (b) The coconut kernel is mixed with a quantity of heated sugar solution, or (c) with heated coconut milk, before it is subjected to the above process.—W. P. S.

Baking powder. F. Rösel. G.P. 322,021, 4.9.18.

The powder consists of a mixture of carbonates with dried and powdered leaven. A fresh leaven, containing about 1.0 acid gives, after air drying at

5°–25° C., a powder containing about 1·8% of effective acid, and also acid-forming enzymes and living yeast cells.—A. G.

Cheese; Process of making Emmenthal or Swiss —. C. F. Doane. E.P. 148,724, 21.1.20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Pelletierine and methylpelletierine. G. Tanret. Bull. Soc. Chim., 1920, 27, 612–624.

THE author reaffirms previous results (Comptes rend., 1880, 90, 697) as to the properties of pelletierine and methylpelletierine, found in the bark of the pomegranate tree, and refutes the statements of Hess and Eichel (J., 1918, 559 A) as to the non-existence of optically active forms of these alkaloids. A number of salts and derivatives of the

alkaloids have been prepared. (Cf. J.C.S., 1920, i., 499.)—W. G.

Phenyl derivatives of arsenious acid; Iodometric estimation of —. P. Fleury. Bull. Soc. Chim., 1920, 27, 699–704.

FOR the estimation of each component in a mixture of arsenious, phenylarsine, and diphenylarsine chlorides and triphenylarsine a known amount of the mixture is dissolved in benzene, and the solution is extracted with aqueous sodium hydroxide. The extract, which contains the arsenious acid and phenylarsine oxide, is acidified with hydrochloric acid until the acidity is approximately N/10; an equal volume of alcohol is added, and the mixture is titrated with standard iodine. This titration gives the amount of phenylarsine chloride present in the original mixture. An excess of sodium bicarbonate is added, and the titration continued till the second end-point is reached. The additional iodine required is equivalent to the arsenious chloride originally present. The benzene solution left after the extraction is titrated with standard iodine, the amount required being equivalent to the diphenylarsine chloride and triphenylarsine originally present. To the liquid resulting from the titration excess of aqueous sodium bicarbonate is added, and the liquid is extracted with chloroform. The extract contains the triphenylarsine oxide, and if the aqueous solution is acidified and again extracted with chloroform the second extract will contain the diphenylarsenic acid, which may be obtained in a crystalline form on evaporation of the solvent.

—W. G.

Diphenylarsenious chloride and cyanide. (Diphenylchloroarsine and diphenylcyanoarsine.) G. T. Morgan and D. C. Vining. Chem. Soc. Trans., 1920, 117, 777–783.

TRIPHENYLARSINE was prepared on an experimental technical scale by the interaction of arsenious chloride, chlorobenzene, and sodium in an inert medium, e.g., xylene, using a steel reaction vessel provided with heating and water cooling arrangements and fitted with a stirrer, reflux condenser, a glass reservoir for holding the liquid reagents, and a sodium dropping apparatus. The chief feature of the method is that the sodium is melted under a layer of xylene in this apparatus and allowed to run gradually through a silica sight glass into the other reagents mixed in the reaction vessel, the temperature being maintained at 70° C. The product is isolated without any addition of water by filtering whilst warm from the precipitate of sodium chloride and distilling off the solvent, when triphenylarsine remains as a pale yellow crystalline mass. This was converted into diphenylchloroarsine by heating with arsenious chloride for 3 hrs. in a rotating autoclave and fractionally separating the product by distillation in a current of carbon dioxide at reduced pressure. Diphenylarsenious cyanide was most conveniently obtained by heating diphenylchloroarsine with a 10% excess of silver cyanide in a glass-lined rotating autoclave for 3 hrs. at 150°–160° C. The yield of cyanide of m.p. 28° C. (90% pure) was about 92% of the theory. Other methods in preparing this substance from diphenylarsenious oxide, diphenylcacodyl, and diphenylarsenious sulphide are also described.—G. F. M.

Quinol [; *Reactions of* —]. J. Messner. Pharm. Zentralh., 1920, 61, 454–455.

QUINOL reduces silver nitrate in the cold and changes the colour of Fehling's solution to green, but actual reduction of the copper, with precipitation of cuprous oxide, takes place only after long contact or when the mixture is heated. Statements in literature that Fehling's solution is reduced in the cold and silver nitrate only when heated with

quinol are incorrect. The reactions are of little, if any, use for differentiating between quinol and catechol.—W. P. S.

Catalytic oxidation by unsaturated compounds (oils, hydrocarbons, etc.). J. Bougault and P. Robin. *Comptes rend.*, 1920, 171, 353–355.

DICHLOROETHYL sulphide in solution in turpentine oil when exposed to the air is oxidised to dichloroethyl sulphoxide, $\text{SO}(\text{C}_2\text{H}_4\text{Cl})_2$, m.p. 112°C . The turpentine may be replaced as solvent by various unsaturated oils or hydrocarbons. If pure dichloroethyl sulphide or its solution in a saturated oil is exposed to the air it does not undergo oxidation.

—W. G.

$\beta\beta$ -Dichloroethyl sulphide; Volumetric estimation of —. W. F. Holley. *Chem. Soc. Trans.*, 1920, 117, 898–902.

THE formation of a crystalline double salt with cuprous chloride, of the constitution $[(\text{C}_2\text{H}_4\text{Cl})_2\text{S}]\text{Cu}_2\text{Cl}_2$, is utilised for the volumetric estimation of $\beta\beta$ -dichloroethyl sulphide in mustard gas. Higher chlorinated compounds do not thus react with cuprous chloride. About 1 g. of the sample is weighed into a 100 c.c. stoppered flask, 10 c.c. of a standardised, freshly prepared solution of cuprous chloride in absolute alcoholic hydrogen chloride is added from a burette, the contents of the flask are allowed to remain for 10 mins. in the cold, with occasional agitation, and are then diluted by the addition of 50 c.c. of 5% sodium chloride solution. After mixing well, the contents of the flask, which now measure 59.5 c.c., are filtered through glass wool, and the excess of copper is estimated in an aliquot portion of the filtrate by means of potassium iodide and thiosulphate in the usual way, after oxidising with hydrogen peroxide and boiling three times nearly to dryness to remove the excess of volatile oxidising agents present. The total copper is determined by a blank experiment, and the difference represents the $\beta\beta$ -dichloroethyl sulphide in terms of N/10 thiosulphate, 1 c.c. of which is equivalent to 0.0159 g.—G. F. M.

Tetranitromethane; Effect of reducing agents on — and a rapid method of estimation [and estimation of hydrazine]. A. Baillie, A. K. Macbeth, and N. I. Maxwell. *Chem. Soc. Trans.*, 1920, 117, 880–884.

TETRANITROMETHANE is rapidly converted into nitroform when shaken with aqueous alkaline solutions of reducing agents, such as sulphites, arsenites, sodium potassium tartrate, or hydrazine. If potassium hydroxide is used to keep the solution alkaline, the nitroform separates out as its sparingly soluble potassium salt. The reaction proceeds with sulphites, for example, according to the equation $\text{C}(\text{NO}_2)_4 + \text{K}_2\text{SO}_3 + 2\text{KOH} = (\text{NO})_2\text{CK} + \text{K}_2\text{SO}_4 + \text{KNO}_2 + \text{H}_2\text{O}$. With aqueous solutions of hydrazine the reduction is quantitative, and measurement in a nitrometer of the volume of nitrogen evolved, according to the equation, $\text{NH}_2\text{NH}_2 + 2\text{C}(\text{NO}_2)_4 + 4\text{KOH} = 2(\text{NO})_2\text{CK} + 2\text{KNO}_2 + \text{N}_2 + 4\text{H}_2\text{O}$ affords a convenient method for estimating tetranitromethane, even in the presence of nitric or nitrous acid. Conversely tetranitromethane may be employed for the estimation of hydrazine in solutions of its salts.—G. F. M.

Nitric esters; Decomposition of —. R. C. Farmer. *Chem. Soc. Trans.*, 1920, 117, 896–898.

A DIRECT decomposition of nitric esters under the influence of hydrolytic agents into aldehydes, ketonic acids, and formic and oxalic acids as postulated by Lowry and others (*J.*, 1920, 558A) does not take place, but such oxidation as may occur is always preceded by hydrolysis into nitric acid and the alcohol. When the conditions are

such that the alcohol is protected from oxidation, as, for example, in the case of glycerol by continuous removal as glycerophosphoric acid or by the presence of further nitro-groups, or when the oxidising action of the nitric acid is suppressed by the presence of reducing agents or of sulphuric acid, the alcohol is readily regenerated as such on hydrolysis, thus proving that the first stage in the decomposition is an ester hydrolysis of the normal type. The hydrolysis is, moreover, shown to resemble that of other esters in the relationship between velocity and concentration of hydrogen or hydroxyl ions, and the bearing of this relationship on the stabilisation of nitric esters by means of weak alkalis is shown. The ordinary hydrolytic decomposition passes therefore through the phases: incipient ester hydrolysis; internal oxidation, possibly to an alcohol peroxide; formation of an aldehyde; and decomposition to hydroxy acids. The non-hydrolytic decomposition of nitric esters in the absence of water, by nitric peroxide, is slow, but autocatalytically accelerated, and the action of feeble alkalis in combating acid hydrolysis is shown by the stabilising influence of weak bases such as diphenylamine; stronger bases, on the other hand, such as benzylamine or aniline, cause an even more rapid decomposition (aminolysis).—G. F. M.

Acetaldehyde and acetic acid; Conversion of acetylene into —. B. Neumann and H. Schneider. *Z. angew. Chem.*, 1920, 33, 189–192.

FOR the conversion of acetylene into acetaldehyde on the laboratory scale the best results were obtained by leading the gas with vigorous mechanical stirring into 96% acetic acid containing 3% of mercuric sulphate in solution, the temperature being maintained at about 30°C . Under these conditions nearly 90% of the theoretical yield was obtained. At 40° – 50°C . the rate absorption was actually greater, but the percentage yield of acetaldehyde was reduced to 70–80%. Using a dilute sulphuric acid medium instead of acetic acid the reaction was more erratic, and under favourable circumstances only 70–75% yields were obtained. The best results in the direct conversion of acetylene to acetic acid were obtained by using the above mercuric sulphate-acetic acid catalyst with the addition of vanadium pentoxide, acetylene and oxygen being led in alternately. Yields of acetic acid up to 83% were obtained.—G. F. M.

Sodium formate; Factors in the conversion of — to oxalate. E. H. Leslie and C. D. Carpenter. *Chem. and Met. Eng.*, 1920, 22, 1195–1197.

IN the conversion of sodium formate to oxalate by heating it with caustic soda, the best results are obtained by using approximately 1% of caustic soda and a pressure of 14 in. of mercury at 350°C . The process should be a continuous one in which small quantities of formate only are subjected to these conditions at any one time. A theoretical discussion of the principles underlying the process is given.—A. R. P.

Thymol; Synthesis of — from p-cymene. M. Phillips and H. D. Gibbs. *J. Ind. Eng. Chem.*, 1920, 12, 733–734.

p-CYMESE was isolated from a crude oil derived from a sulphite spruce pulp mill and purified by treatment with sulphuric acid, washing, drying and redistillation. When nitrated it yielded nitrocymene, which was reduced to cymidine by means of iron powder and hydrochloric acid. This was converted into a mixture of *o*- and *p*-cymidinesulphonic acids, and these, in turn, into the corresponding diazo-cymenesulphonic acids, both of which yielded cymene-3-sulphonic acid when treated with ethyl alcohol and copper powder, and by fusing the sodium salt of this acid with sodium hydroxide thymol was formed.—C. A. M.

Volatile oil of Mosla grosseserrata, Maxim. Y. Murayama. J. Pharm. Soc. Japan, 1920, No. 459, 389—408. (Cf. Furukawa and Tomizawa, J., 1919, 877 A.)

THREE samples of oil from wild plants had the following characters:—Sp. gr. 0.9985 at 15° C., 0.9543 at 15° C., 1.0488 at 19° C., saponif. value, 33, 23, —; saponif. value after acetylation, 66.6, 54.5, —; α_D (1 dm.) = -3.75°, -3.2°, -11.75°; methoxy content, 7.07%, —, 11.38%; phenol content, 20%, —, —. Thymol, methyleugenol, *p*-cymol (*p*-hydroxyisopropylbenzoic acid, m.p. 153° C.), a terpene, and a sesquiterpene, b.p. 136° C. at 12 mm. were identified in the first sample, thymoquinol and thymol in the second, and myristicin in the third sample. A sample of oil from the cultivated plant had a dark brown colour, sp. gr. at 15° C., 0.9006; acid value, 0; saponif. value, 37.0; saponif. value after acetylation, 49.2; α_D = -4.5°, methoxy content, 31%. Thymoquinol (0.9%), thymol (13%), and a terpene were detected in the oil.—K. K.

Nitroglycerol; Determination of —. H. D. Richmond. Analyst, 1920, 45, 260—265.

THE following method is described for the analysis of commercial nitroglycerol solutions (*Liquor trinitrini*, *L. glonoini*):—5 c.c. of the sample is mixed with 50 c.c. of water and titrated with *N*/10 barium hydroxide solution. After deducting 0.1 from the number of c.c. of alkali solution used, the result is divided by 1.02 (correction for slight hydrolysis). To determine the nitroglycerol, 5 c.c. of a 10% solution plus 5 c.c. of 90% alcohol, or 10 c.c. of a 5% solution, is treated with 25 c.c. of *N*/2 alcoholic sodium hydroxide solution; 10 c.c. of the latter solution is required for 20 c.c. of a 1% nitroglycerol solution. After 5 mins. phenolphthalein is added, and the excess of alkali titrated with *N*/1 acid. If more than 4 c.c. of acid is used the determination must be repeated, increasing the alcoholic strength, since the final solution must contain at least 81% of alcohol. The volume of alkali solution used is corrected for the acidity as found above; then 1 c.c. of *N*/1 alkali solution is equivalent to 0.05675 g. of nitroglycerol. If 2 c.c. of "100-vol." hydrogen peroxide is added before the addition of alkali, the final alcoholic strength has much less influence on the titration.—W. P. S.

PATENTS.

Protocatechuic aldehyde; Manufacture of —. Confectionery Ingredients, Ltd., F. E. Matthews, A. T. King, and T. Kane. E.P. 145,871, 1.4.19.

THE acid chloride of any suitable acyl derivative of protocatechuic acid such as the acetate, benzoate, carbonate, or *p*-toluenesulphonate, or of the benzyl ether of protocatechuic acid is reduced to the corresponding derivative of protocatechuic aldehyde by treatment in an inert solvent at boiling temperature with hydrogen in presence of a hydrogenating catalyst, such as palladium or nickel. When the evolution of hydrogen chloride has ceased the aldehyde is recovered from the filtered liquid in the form of its bisulphite compound.—G. F. M.

Esters; Methods of forming —. E. C. R. Marks. From U.S. Industrial Alcohol Co. E.P. 147,337, 23.6.19.

ESTERS of the higher alcohols are produced by

partial esterification in presence of a dehydrating agent, separating the latter, and continuing the esterification at a higher temperature. For instance, a mixture of 3205 g. of fusel oil (sp. gr. 0.8268), 256 g. of sulphuric acid (sp. gr. 1.84), and 2564 g. of glacial acetic acid is kept for 24 hrs. at ordinary temperature, with occasional agitation. The aqueous layer containing all the sulphuric acid is separated, and the oily layer distilled at 100° C. until the separation of water ceases, indicating that esterification is complete. The ester layer in the distillate is from time to time separated from the water and returned to the still. The still contents are finally neutralised with 30% sodium hydroxide solution, the aqueous sodium acetate layer, which separates, being drawn off, and distilled at 100° C. to recover any amyl acetate it may contain.—G. F. M.

Silver salts of aliphatic α -amino acids; Manufacture of complex —. H. R. Napp. E.P. 148,074, 23.9.19.

COMPLEX silver salts of glycine are obtained by treating silver oxide or organic or inorganic salts of silver with a solution containing about 5 equivalents of the amino-acid, and crystallising the filtered solution at temperatures below 0° C. The complex salt obtained is more stable than the normal silver salt. It is soluble in water, to which it imparts an alkaline reaction. Sodium hydroxide causes no immediate precipitation of silver oxide, and no precipitate is produced with albumin. The compound has no irritating effect, and this, together with its other properties, renders it suitable for therapeutic purposes. Complex silver salts of other aliphatic α -amino-acids have similar properties, and are prepared by evaporating solutions of silver oxide or its salts in excess of the respective amino-acids.—G. F. M.

Medicinal oil preparations in dry form. H. V. Dunham. E.P. 148,587, 30.1.19.

SEE U.S. Pat. 1,302,487 of 1919; J., 1919, 511 A.

Soluble compounds from coal. G.P. 306,471. See IIA.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Printing-out papers; Recording the characteristic curve of —. F. Formstecher. Phot. Korrt., 1920, 57, 191—197.

A "FIRST" print on the paper to be examined is made by exposing through a paper-scale of known opacities. After rendering the base of this print transparent by soaking in paraffin oil or wax, a second print is made on any suitable paper through the first print and the exposure scale placed at right angles to one another. Lines of equal density, "Iso-opaken," on the second print represent the required characteristic curve.—B. V. S.

Print-out papers; Colour [of the image] in — and factors affecting it. F. Formstecher. Deuts. Opt. Wochenschr., 1920, 33—34. Chem. Zentr., 1920, 91, IV., 156.

THE colour of the printing image depends on the size of the precipitated silver particles, which is affected by the initial condition of the sensitive silver salt and also by the strength of the printing light and by moisture. Emulsions with a low proportion of citrate give blue images, the particles becoming finer grained and the colour redder with increasing quantities of citrate. The redder images have also a softer gradation.—B. V. S.

XXII.—EXPLOSIVES ; MATCHES.

Nitrocellulose; Viscosity of solutions of — in mixtures of acetone and water. I. Masson and R. McCall, Chem. Soc. Trans., 1920, 117, 819—823. (Cf. J., 1920, 172 r).

THE viscosity of sols of nitrocellulose in anhydrous or aqueous acetone rises rapidly within a few minutes of mixing to a maximum value and then gradually falls, and the same is true with ether-alcohol sols of minimum viscosity, but the more widely the composition of the solvents deviates from this "optimum" value the longer is the time taken in attaining the highest viscosity. The viscosities of nitrocellulose in anhydrous acetone are relatively high, but traces of water have a marked effect in lowering the viscosity down to a certain minimum value, after which it again rises with further addition of water, until when upwards of 12% of water is present the liquid no longer permits of the dispersion of the nitrocellulose. The optimum solvent composition at which viscosity is at a minimum is not the same for all kinds of nitrocellulose, nor is it quite independent of concentration; in fact, the gel absorbs selectively varying quantities of the fluid, and hence the composition of the fluid phase at equilibrium is not necessarily the same as that of the solvent before admixture with the nitrocellulose. None of the equations which have been hitherto suggested for correlating the viscosity of sols with the concentration of the disperse phase is applicable to the sols under discussion, except over small ranges of concentration.—G. F. M.

Blasting explosive; Modified TNT (mixture of Trojan grenade powder and trinitrotoluene) as a —. C. E. Munroe and S. P. Howell. U.S. Bureau of Mines. Reports of Investigations, June, 1920.

THE composition of Trojan grenade powder is: Moisture, 0.71%; nitrostarch, 21.37%; oils, 1.13%; sodium nitrate, 37.62%; ammonium nitrate, 33.34%; ammonium chloride, 0.39%; carbon and ash, 2.44%. It gave the following results: Velocity of detonation, 3741 m. per sec.; Trauzl block, 216 c.c.; small block, 15.9 mm.; pressure, 8836 kg. per sq. cm.; unit defective charge, 256 g.; calorimeter, 1037.1 cal. per kg.; volume of gas, 131.7 l. Comparative tests with 40% ammonia-dynamite gave: 3157 m. per sec.; 202 c.c.; 12.8 mm.; 8921 kg. per sq. cm.; 243 g.; 1122 cal. per kg.; 140 l. Large surplus stocks of Trojan grenade powder deteriorated on storage on account of deliquescence and when submitted to the influence test with a No. 8 detonator were found to be too insensitive for use. A mixture of equal parts of the powder and trinitrotoluene, however, proved to be a satisfactory explosive and was styled "modified TNT." The craters produced on explosion were larger than those obtained with trinitrotoluene alone. The mixture is free from dust and is consequently more readily packed, with less risk to the health of the workers. It may be packed in paraffined paper cases, a cartridge measuring 14" x 8" having apparent sp. gr. 1.15, or it may be used in loose form in containers. A detonator of the same grade as required for trinitrotoluene must be used.

—W. J. W.

Explosives; Apparatus for determining the explosion temperature of —. A. Langhaus. Z. ges. Schiess- und Sprengstoffw., 1920, 45, 161—163.

THE apparatus comprises a rectangular or cylindrical lead block surrounded on all sides except the top by an iron or copper jacket, and having drilled sockets in which are placed test tubes containing the samples of explosive, an additional one being provided for a thermometer. To reduce the

weight of the apparatus it may be constructed of iron, copper, or brass, and drilled to admit of the insertion of small leaden containers, preferably of conical shape to facilitate their removal for re-melting. To avoid adherence of the lead to the block, an iron or copper sheath may be used. The explosive may be kept under observation during the test by a suitable arrangement of lateral and vertical holes and inclined mirrors.—W. J. W.

Nitrometer; Explosions during operations with the —. Witt. Z. ges. Schiess- und Sprengstoffw., 1920, 45, 145.

NITROGLYCERIN and trinitrotoluene residues, obtained by extraction with ether in a Soxhlet apparatus, and then dried in a vacuum desiccator and treated with sulphuric acid for the nitrogen estimation, were found to ignite when transferred to the nitrometer. In some cases an explosion resulted during shaking in the apparatus. Impure ether is the origin of the trouble, to avoid which the purest quality must be used; the extract is then completely dried in a vacuum desiccator and preferably heated to 50° C., only a very slight loss of nitroglycerin resulting at this temperature.

—W. J. W.

Nitric esters. Farmer. See XX.

PATENTS.

Nitrocellulose; Stabilisation of — and apparatus therefor. B. van der Laan. E.P. 147,378, 2.10.19.

FOR stabilising and simultaneously sub-dividing nitrocellulose use is made of a rotary boiler of wood or aluminium provided with paddles and having two opposite manholes. Steam is introduced by means of a pipe through the axis of the vessel, exhaust steam escaping through a pipe which is separated from the interior of the boiler by a sieve bottom. The contents may be discharged into a hopper, whence they can be passed to the pulping machine by pumps. The process ensures energetic and rapid stabilisation of the material, economises steam consumption, and simplifies the discharge of the stabilised nitrocellulose.—W. J. W.

Explosives; Gelatinisation of cellulose nitric esters in the manufacture of —. W. Rintoul and T. J. Nolan, Assrs. to Nobel's Explosives Co., Ltd. U.S.P. 1,318,711, 3.8.20. Appl. 19.5.19.

SEE E.P. 131,389 of 1918; J., 1919, 795 A.

Explosive substances; Preventing danger of explosion in the preparation and handling of dangerous —. G. Darier and C. Gondet, Assrs. to Soc. d'Etudes Chim. pour l'Ind. U.S.P. 1,349,111, 10.8.20. Appl., 14.9.18.

SEE E.P. 130,166 of 1918; J., 1919, 712 A.

XXIII.—ANALYSIS.

Potassium hydrogen phthalate; Use of — as standard in alkalimetry. F. D. Dodge. J. Amer. Chem. Soc., 1920, 42, 1655—1656.

POTASSIUM hydrogen phthalate for use as a standard in alkalimetry should be crystallised above 20° C., whereby the formation of a more acid salt, $2\text{KHC}_8\text{H}_4\text{O}_4 \cdot \text{C}_8\text{H}_4\text{O}_4$, is effectually prevented. (Cf. J., 1920, 530 A.)—J. F. S.

Magnesia mixture. O. Kulmt. Chem.-Zeit., 1920, 44, 5*6.

MAGNESIA mixture for the precipitation of phosphoric acid if prepared without the addition of ammonia may be kept indefinitely in glass bottles without the glass being attacked. The requisite quantity of ammonia is added after the phosphate solution has been treated with a slight excess of the reagent.—W. P. S.

Metals; Use of organic solvents in the quantitative separation of —. III. Separation of magnesium from sodium and potassium chlorides. S. Palkin. J. Amer. Chem. Soc., 1920, 42, 1618—1621.

THE chlorides of magnesium, sodium, and potassium are dissolved in the minimum quantity of water (about 1.5 c.c. for 0.5 g.) in a 100—150 c.c. beaker flask, 1 drop of concentrated hydrochloric acid is added, and gradually 25 c.c. of absolute alcohol is dropped into the middle of the beaker while rotating; the sodium and potassium chlorides should precipitate in a uniform granular condition. In a similar manner, while rotating the beaker 25 c.c. of ether (U.S.P.) is added. When the precipitate has agglomerated and the supernatant liquid is nearly clear, the mixture is filtered through a weighed Gooch crucible into a 150 c.c. conical flask, using only mild suction to avoid drying the precipitate too soon. The beaker is washed with a mixture of 1 pt. of alcohol and 4 pts. of ether and the washings passed through the filter. The filtrate is evaporated to dryness and the residue treated with 10 c.c. of alcohol. One drop of concentrated hydrochloric acid is added and the mixture warmed until practically all has dissolved. The beaker is then rotated, 50 c.c. of ether slowly added, and the mixture kept for 20 min. The precipitate is collected in the same Gooch crucible, washed as before, then dried, ignited, and weighed. The filtrate is evaporated to dryness, the residue treated with 5—10 c.c. of hydrochloric acid and a little water, and the magnesium estimated in the usual manner.—J. F. S.

Halogens in organic compounds; Liquid ammonia-sodium method for the estimation of —. F. B. Dains and R. Q. Brewster. J. Amer. Chem. Soc., 1920, 42, 1573—1579.

CHLOROFORM, bromoform, chloral hydrate, bromal hydrate, methyl cyanide, benzyl cyanide, cyanoacetic ester, ethylidene chloride, tetrachloroethylene, and acetylene tetrachloride all form considerable amounts of sodium cyanide during the estimation of halogens by the liquid ammonia-sodium method (J., 1918, 448A). The halogen in these substances may be estimated by Clifford's modification of the process (J., 1919, 663A). (Cf. J.C.S., Oct.).—J. F. S.

Nitrotes and nitrites, antipyrine (in pyrimidine), phenol, and α - and β -naphthols; Colour tests for —. A. Escaich. J. Pharm. Chim., 1920, 22, 138—141.

IN applying the test for nitrates, previously described (J., 1918, 484A), to waters rich in chlorides, it is advisable, after reduction with amalgamated aluminium and filtration, to add sufficient silver nitrate solution to precipitate the chlorides, and then to filter before applying the colour test for nitrites. Magnesium may be activated similarly to aluminium, by immersion in mercuric cyanide solution, and is preferable to the latter metal for the detection of nitrates in diluted wines. For the detection of antipyrine in pyrimidine 1 g. dissolved in 10 or 20 c.c. of water is treated with 1 or 2 drops of a 5% solution of alkali nitrite and 5 drops of sulphuric acid. When the transient blue colour which appears has vanished, addition of 0.05—0.1 g. of lead peroxide will produce, if antipyrine was present, a violet colour changing to permanent cherry-red. The following modification of the quinone-imide test for phenol (or aniline after its conversion into phenol by diazotising and boiling with water) is very sensitive:—10—15 c.c. of the solution to be tested is treated with 5—10 drops of ammonia, 0.05—0.1 g. of sodium persulphate, and 4 or 5 drops of N/10 silver nitrate solution. A green coloration is produced which rapidly inten-

sifies and changes to blue for concentrations of phenol exceeding 0.05 g. per litre, and which becomes yellow for lower concentrations. α -Naphthol in aqueous alcoholic solution, treated with sodium nitrite and a few drops of acid mercuric sulphate solution, produces a fine red coloration and then a precipitate resembling mercuric iodide. β -Naphthol yields a yellowish precipitate under similar conditions.—J. H. L.

Glycol; Determination of —. B. Müller. Chem.-Zeit., 1920, 44, 513—515.

THE bichromate and acetin methods used in glycerol analysis are trustworthy for the determination of ethylene-glycol, but the acetin method can be applied only when the glycol is in a concentrated form. In the bichromate method the mixture must be heated for 4 hrs. to ensure complete oxidation; the excess of bichromate used may be determined iodometrically. Oxidation of the glycol with chromic acid and sulphuric acid and gravimetric determination of the carbon dioxide formed also yields accurate results. Benedikt and Zsigmondy's permanganate method cannot be used for the determination of ethylene-glycol, since the latter is not oxidised completely to oxalic acid.—W. P. S.

Spectrophotometry; Combination of fractionation with — in proximate organic analysis. W. E. Mathewson. J. Amer. Chem. Soc., 1920, 42, 1277—1279.

THE spectrophotometric method of estimating dye-stuffs may be applied to colourless organic compounds by first converting them into coloured compounds, which are separated from other coloured substances by extraction with suitable solvents. Procedures are described for the estimation of sulphanic acid, acetone, and β -naphthol depending on their condensation respectively with picryl chloride, 2,4-dinitrophenylhydrazine, and diazotised sulphanic acid.—J. K.

PATENTS.

Coal; Apparatus for analysing or estimating volatile constituents of —. A. Naito. E.P. 147,254, 7.4.19.

A WEIGHEN sample of coal is distilled in a closed crucible, and the gas is led into kerosene in a closed flask fitted with a reflux condenser. Water accumulates at the bottom of the flask, and tar is dissolved in the kerosene, while the gas passes on to a measuring bell immersed in a tank of water, the volume of gas being measured by the amount of water drawn off from the tank. When distillation is complete, the water is separated from the kerosene and measured, while the increase in the weight of the kerosene indicates the amount of tar dissolved.—W. F. F.

31,799 (1919). Woodall, Duckham, and Jones, and Duckham. Introduction of steam into vertical retorts or ovens. (150,589.) Sept. 15.

2789 (1920). Muhlfeld. Burning pulverulent or liquid fuel in furnaces. (150,230.) Sept. 8.

III.—TAR AND TAR PRODUCTS.

COMPLETE SPECIFICATION ACCEPTED.

13,619 (1919). Tcherniac. Reduction of aromatic nitro-compounds. (150,412.) Sept. 15.

IV.—COLOURING MATTERS AND DYES.

APPLICATION.

Cassella und Co. Manufacture of a colour of the anthraquinone series. 25,263. Sept. 1. (Ger., 1.9.19.)

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Hollaender. Production of a plastic substance. 25,079. Aug. 31.

Hollaender. Production of artificial fibres, films, etc. 25,080. Aug. 31.

Jenkins. Apparatus for drying, cleansing, or carbonising wool etc. 25,417. Sept. 3.

Jenner. Apparatus for drying varnished paper etc. 25,061. Aug. 31.

Kirschbraun. Waterproof paper and process of making same. 25,753. Sept. 7.

Marx. Paper-making etc. machines. 25,092. Aug. 31.

COMPLETE SPECIFICATION ACCEPTED.

29,474 (1919). Gratz. De-acidification of raw wood pulp liquor. (150,171.) Sept. 15.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Boucherie. Impregnating animal and vegetable fibres. 25,160. Aug. 31. (Fr., 15.6.20.)

Hindle. Printing cotton and woven fabrics. 25,493. Sept. 4.

Leach, Pollitt, and Willows. Production of pattern effects in cotton etc. fabrics and silk. 25,294. Sept. 2.

Surpass Chemical Co. Process of dyeing. 26,079. Sept. 10. (U.S., 30.1.20.)

COMPLETE SPECIFICATION ACCEPTED.

29,410 (1919). Watremez. Scouring fibres of vegetable origin to facilitate and accelerate subsequent bleaching. (139,457.) Sept. 8.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Goldschmidt A.-G. Production of alkali sulphate and hydrochloric acid. 26,001. Sept. 9. (Ger., 9.9.19.)

Hansford. Manufacture of neutral sulphate of ammonia. 25,505. Sept. 4.

Nitrogen Corporation. Production of sodium bicarbonate and hydrogen. 25,359. Sept. 2. (U.S., 7.2.20.)

Pattison (Mathieson Alkali Works). Recovery of ammonia. 25,402. Sept. 3.

Pfannenschmidt. Acid chambers, acid towers, acid mains, etc. 25,585. Sept. 6. (Ger., 8.9.19.)

Robertson, and Robertson & Sons. Recovery of high-boiling acid. 25,206. Sept. 1.

Soc. l'Air Liquide. Direct synthesis of ammonia. 25,766. Sept. 11. (Fr., 12.9.19.)

Terrell. Preparation of thoria and thorium salts. 25,435. Sept. 3.

United Alkali Co. (Barker). Electrolytic cells for producing alkali chlorates. 26,104. Sept. 10.

Zack. Separating oxygen and nitrogen. 25,423. Sept. 3. (Switz., 15.10.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

15,296 (1919). Carborundum Co. (Hutchins). Purifying aluminous materials. (150,116.) Sept. 8.

15,765 (1919). Marks (Nitrogen Products Co.). Apparatus for fixation of nitrogen. (150,127.) Sept. 8.

31,909 (1919). Pestalozza. Electrolytic apparatus for direct production of hypochlorites. (150,214.) Sept. 8.

32,672 (1919). Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of potassium sulphate. (137,519.) Sept. 15.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

British Thomson-Houston Co. (General Electric Co.). Finishing glass. 25,982. Sept. 9.

Clarke and Gaudin. Drying china clay. 25,075. Aug. 31.

Marino. Metallising articles of porcelain, china, etc. 26,175. Sept. 11.

COMPLETE SPECIFICATIONS ACCEPTED.

674 (1920). British Thomson-Houston Co. (General Electric Co.). Substances for coating glass surfaces. (150,598.) Sept. 15.

15,973 (1920). Ueda. Process for treating glass surfaces. (144,737.) Sept. 15.

IX.—BUILDING MATERIALS.

APPLICATIONS.

John. Roofing, walling, etc. material. 25,137. Aug. 31.

Lloyd and Maclean. Manufacture of cement. 26,017. Sept. 10.

Low, Smith, and Tullock. Composition for heat insulation. 25,997. Sept. 9.

Ziekgraf. Production of artificial limestone. 26,048. Sept. 10.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Baines, Clarke, and De Lavand. Heat treatment of metallic etc. subjects. 25,145. Aug. 31.

British Thomson-Houston Co. (General Electric Co.). Arc-welding compositions. 25,888. Sept. 8.

Cyclops Steel Co. Alloys. 25,788. Sept. 7. (U.S., 3,10,19.)

De Bats. Melting and casting metals. 25,018. Aug. 30.

Erikson. Process and furnace for reducing metallic oxides. 25,652. Sept. 6.

Festa. Furnaces for fusion of steel etc. 25,262. Sept. 1. (Fr., 5,12,19.)

Schiff and Vivian. Conversion and separation of complex ores and minerals. 25,605. Sept. 6.

Wichmann. Manufacture of alloys. 25,218. Sept. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

7186 (1914). Chiapponi, Hesse, and Rauschenplat. Removal of iron from oxide or roasted sulphide tin ores. Sept. 15.

10,338 (1919). Speer. Chrome nickel steel. (150,020.) Sept. 8.

12,796 (1919). Whyte. Case-hardening, tempering, etc. (150,035.) Sept. 8.

12,908 (1919). Cohen and Catterall. Furnaces for melting and refining metals. (150,012.) Sept. 8.

13,247 (1919). Coles. Continuous electrolytic production of copper wire. (150,063.) Sept. 8.

14,151 (1919). British Thomson-Houston Co. (General Electric Co.). Annealing metal sheets. (150,137.) Sept. 15.

14,517 (1919). Gaunt, Walters, Marle, and Gibbons Bros. Furnaces for heat treating metals. (150,099.) Sept. 8.

15,109 (1919). Martin. Water concentration of ores. (150,113.) Sept. 8.

16,411 (1919). Wurstenberger and Frei. Manufacture of fluid for preventing selective corrosion of copper tubes etc. (130,323.) Sept. 8.

16,833 (1919). Mellor. Reduction of metals to powder. (150,490.) Sept. 15.

29,504 (1919). Electrolytic Zinc Co. Recovery of zinc by electrolysis. (136,151.) Sept. 15.

1013 (1920). International Nickel Co. Manufacture of nickel and copper. (138,600.) Sept. 15.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Davey, and Electro Metals, Ltd. Operating electrodes of electric furnaces. 25,965. Sept. 9.

Davis. Storage batteries. 25,035. Aug. 30.

Gonin and Roesel. Alkaline storage batteries. 25,999. Sept. 9. (Fr., 10,9,19.)

Powell. Electric batteries. 25,191. Sept. 1.

Stevens. Electric accumulators. 25,825. Sept. 8.

United Alkali Co. (Barker). 26,101. *See VII.*

COMPLETE SPECIFICATIONS ACCEPTED.

13,247 (1919). Coles. *See X.*

20,920 (1919). Gardiner and Duggan. Storage batteries. (150,171.) Sept. 8.

21,582 (1919). De Luca. Electric furnaces. (150,532.) Sept. 15.

29,504 (1919). Electrolytic Zinc Co. *See X.*

31,909 (1919). Pestalozza. *See VII.*

363 (1920). Jackson (Allen Electrolytic Cell Corp.). Electrolytic cells. (150,595.) Sept. 15.

651 (1920). Coles. Zinc battery elements. (150,597.) Sept. 15.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Carmichael and Guillaume. Apparatus for extracting, distilling, etc. oils, greases, sewage, etc. 25,072. Aug. 31.

Dayton Metal Products Co. Hydrogenation apparatus. 25,141. Aug. 31. (U.S., 5,10,18.)

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Barrett Co. Manufacture of resins. 25,811. Sept. 7. (U.S., 8,3,20.)

Hollaender. 25,079. *See V.*

Mitchell. Manufacture of lithopone. 25,282. Sept. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

24,606 (1919). Isaacs. Coating compositions or paints. (150,551.) Sept. 15.

7488 (1920). Pooley and Strevens. Extraction of gum from grass trees. (150,638.) Sept. 15.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Crouch and Speedy. Rubber-mixing. 25,095. Aug. 31.

Feldenheimer, Plowman, and Schidrowitz. Manufacture of rubber. 25,813. Sept. 7.

Goodyear Tire and Rubber Co. Manufacture of vulcanised caoutchouc. 25,810. Sept. 7. (U.S., 10,11,19.)

Kenny and Oetberg. Rubber material. 25,474. Sept. 3.

COMPLETE SPECIFICATION ACCEPTED.

12,928 (1919). Dunlop Rubber Co., Worthington, and Hyde. Treatment of raw rubber. (150,043.) Sept. 8.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

British United Shoe Machinery Co., and Reid. Finishing etc. leather goods etc. 25,050. Aug. 30.

Turner Tanning Machinery Co. Machine for treating hides, skins, and leather. 24,969. Aug. 30. (U.S., 30,8,19.)

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Johnson (Badische Anilin und Soda-Fabrik) Manufacture of fertilisers. 25,892. Sept. 8.

Soc. d'Etudes Chim. pour l'Industrie. 25,336. *See XX.*

Soc. d'Etudes Chim. pour l'Industrie. Manufacture of manures. 25,337-8, 25,340-1, 25,344-5. Sept. 2. (Switz., 26,9 and 15,11,19, 2,3,20.)

COMPLETE SPECIFICATION ACCEPTED.

10,592 (1919). Young and Watson. Utilising sewage sludge to produce marketable manure and other products. (150,375.) Sept. 15.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

White (Perkins Glue Co.) Modifying or converting starch. 26,074. Sept. 10.

COMPLETE SPECIFICATION ACCEPTED.

31,741 (1919). Ballochmyle Creamery Co., and McCrone. Process of sugar-boiling. (150,588.) Sept. 15.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Herriott (Deerr). Recovery of alcohol and concentrated slop from fermented materials. 26,159. Sept. 11.

Jensen. Manufacture of yeast. 26,152. Sept. 11. (Denmark, 12.9.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

7552 (1917). Weizmann. *See* XX.

11,302 (1917). Diamalt A.-G. *See* XX.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Atmosteral, Ltd., and Dunsford. Antiseptics, disinfectants, etc. 26,086. Sept. 10.

Bate and Dexter. Utilising chlorpicrin. 25,773. Sept. 7.

Carmichael and Guillaume. 25,072. *See* XII.

Clayton. Preservatives for margarine, butter, cream, etc. 25,034. Aug. 30.

Cocks and Wayman. Beverage. 25,225. Sept. 1.

Hardcastle. Food for animals etc. 25,195-6. Sept. 1.

Springhorn. Treatment of peat moss for purification of sewage effluents etc. 25,485. Sept. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

4740 (1919). Linden. Drying sewage sludge or other wet material. (150,368.) Sept. 15.

10,592 (1919). Young and Watson. *See* XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Dayton Metal Products Co. 25,144. *See* XII.

Röhm und Haas. Manufacture of alkylene-cyanhydrins. 25,261. Sept. 1. (Ger., 3.9.19.)

Sander. Production of synthetic alcohol. 25,738. Sept. 7.

Soc. d'Etudes Chimiques pour l'Industrie. Conversion of cyanamide into urea. 25,336. Sept. 2. (Switz., 26.9.19.)

White (Spirocid Corp.). Producing medicinal compounds. 25,471. Sept. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

7552 (1917). Weizmann. Fermentation processes for producing acetone and butyl alcohol. (150,360.) Sept. 15.

11,302 (1917). Diamalt A.-G. Production of saccharic acid and tartaric acid from carbohydrates. (108,494.) Sept. 15.

13,502 (1919). Imray (Soc. Chem. Ind. in Basle). Manufacture of allyl ester of 2-phenylquinoline-4-carboxylic acid. (150,401.) Sept. 15.

13,619 (1919). Tcherniac. *See* III.

22,482 (1919). Soc. des Acieries et Forges de Firminy. Catalytic preparation of acetic acid from acetylene. (132,529.) Sept. 8.

12,753 (1920). Bregeat. Recovery of camphor from gaseous mixtures. (150,654.) Sept. 15.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Middleton. Transfer-processes. 25,619. Sept. 6.

Middleton. Production of three-colour heliochromes. 25,620. Sept. 6.

Mimesa A.-G. Toning baths. 25,762. Sept. 7.

XXII.—EXPLOSIVES; MATCHES.

APPLICATIONS.

Claessen. Manufacture of gelatinous explosives. 25,802. Sept. 7. (Ger., 22.4.20.)

Jones and Kelly. Explosives. 24,984. Aug. 30.

Lundsgaard. Explosives. 25,486. Sept. 3.

I.—GENERAL; PLANT; MACHINERY.

Evaporator design; Studies in —. W. L. Badger and P. W. Shepard. Amer. Inst. Chem. Eng., 27.6.20. Chem. and Met. Eng., 1920, 23, 237-241, 281-281.

This is the first contribution from the Evaporator Experiment Station of the University of Michigan, and deals with the influence of temperature drop and temperature level on heat transmission in a vertical tube evaporator. The following conclusions from the experimental results are given, with the reservation that they must be applied with caution to other types of apparatus. The apparent coefficient of heat transmission in vertical tube evaporators decreases with decrease in temperature drop and approaches zero for zero temperature drop. It increases with boiling point for a given temperature drop (which also means increasing steam temperature). Correcting the apparent heat transmission coefficients for hydrostatic head gives figures which change but little with temperature drop. This remaining change is probably due to increased circulation at increased rates of boiling. The corrected heat transmission coefficients used show considerable differences when the boiling point is increased and the temperature drop held constant. It is impossible to represent heat transmission coefficients for different boiling points, different temperature drops, and different steam temperatures by any expression which does not consider at least two of these three factors.—W. H. C.

Evaporating apparatus; Study of condensation in —. E. Depasse. Bull. Assoc. Chim. Sucr., 1920, 37, 434-444.

In evaporating a liquid particularly liable to incrustation, it was found that incrustation was most rapid where the temperature difference and the amount of evaporation per unit area of heating surface were greatest; in these cases the coefficient of evaporation, K (as defined by Horsin-Déon), was increased and incrustation diminished by reducing the temperature difference. From an investigation of a number of apparatus of different types it is concluded that K varies according to the construction of the apparatus and the nature and concentration of the liquid evaporated. Curves are given showing for the evaporation of pure water in a single unit the relation between the temperature of the heating steam, the temperature difference, and the rate of evaporation per unit area.—J. H. L.

Heat transfer in flues. L. H. Fry. Engineering, 1920, 110, 265-268.

The influence of length and dimensions of flue, the rate of flow of gas, and temperature drop on heat transference in flues has been studied by the aid of a double logarithmic (olog) formula. The results are shown in a number of tables of experimental results and of calculated data, and the formulæ have been applied to the published results of other experimenters to bring them into harmony.—W. H. C.

PATENTS.

Temperature-exchanging apparatus. E. Harter. E.P. 127,565, 6.5.19. Conv., 25.5.18.

A gas which is to gain or lose heat is passed through a centrifugal fan the rotor of which is surrounded by concentric rings of gilled tubes; the tubes carry hot or cold water or other liquid, and the gills are directly in the path of, but are so shaped as to avoid shock to, the issuing gas.—B. M. V.

Tunnel ovens and like structures; Cooling chamber for —. Dressler Tunnel Ovens, Ltd., and C. Dressler. E.P. 149,085, 11.5.19.

The cooling chamber of a tunnel oven is provided with a nest of horizontal or slightly inclined tubes connected with a water supply at the cooler end and with a steam drum at the end nearest the furnace. To prevent the heat of the furnace heating the water in the tubes directly, there may be interposed a passage, built of refractory material, which is only just large enough to permit the goods on their truck to pass.—B. M. V.

Tunnel kiln. P. A. Meehan, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. (A) 1,348,510 and (B) 1,348,511, 3.8.20. Appl., 5.12.19.

(A) A HORIZONTAL kiln for the heat treatment of articles has a port at one end for the entrance and exit of the carrier containing the articles. A high temperature zone is maintained at a distance from the port, and the carrier is reciprocated between the port and the high temperature zone. (B) The combustion chamber for the kiln described in (A) is divided into two longitudinal passages which communicate at one end, forming a continuous passage. Air and fuel enter at the free end of one of the passages, and burnt gas is drawn off at the free end of the other passages.—W. F. F.

Tunnel oven. F. K. Meiser. G.P. 320,800, 4.3.19. Addn. to 319,440 (J., 1920, 475 A).

Gas leads with detachable flexible connexions are arranged in parallel underneath the trolleys bearing the crucibles, each of which thereby obtains a fresh supply of gas.—G. F. M.

Kiln. C. E. Carpenter. U.S.P. 1,349,185, 10.8.20. Appl., 20.11.19.

The floor of a kiln contains a pair of crossed flues communicating at their point of intersection and an annular flue intersecting and communicating with the crossed flues. One of the crossed flues and the annular flue are open at the top to the interior of the kiln and one end of the other crossed flue is open to the stack.—W. F. F.

Pot furnace. E. L. Knoedler, Assr. to Welsbach Co. U.S.P. 1,349,159, 10.8.20. Appl., 1.5.18.

A POT is mounted on horizontal trunnions, so that it can be tipped, and a rotary stirrer is provided, mounted on an inclined axis so that the pot may be tipped without interfering with the stirrer.—W. F. F.

Kiln; Rotary —. A. E. Truesdell and L. F. Phillips. U.S.P. 1,350,750, 21.8.20. Appl., 20.10.16.

AN inclined rotary kiln is heated by combustible gas and primary air, which are supplied at its lower end. The portion of the kiln forming the burning chamber is surrounded by a jacket through which secondary air is passed to preheat it. The secondary air is delivered to the burning chamber at a point intermediate between its ends.—W. F. F.

Decantation apparatus. J. Denöel. E.P. 149,551, 14.10.19.

The liquid containing suspended matter flows in at the top of an inverted funnel, from under the lower edge of which the clear liquid flows up through the outer space to an overflow, while the settled mud flows continuously downwards to a bottom outlet, the apparatus is so proportioned that the liquid falls with decreasing velocity until it reaches the bottom edge of the funnel, and the velocity is not increased on the upward journey of

the clear liquid. To avoid shock and permit the escape of froth, the feed may be from an auxiliary tank to an inlet slightly below the surface of the liquid, and any air rising up the walls of the funnel is permitted to escape through an annular space around the inlet.—B. M. V.

Filter. W. D. Mount. U.S.P. 1,348,036, 27.7.20. Appl., 11.12.19.

A ROTARY drum filter is built up of two end flanges and a series of interchangeable grids forming the cylindrical surface. Each grid covers only a part of the surface, and the abutting edges of all the grids are secured by a single clamping device.

—W. F. F.

Filter. P. C. Forrester. U.S.P. 1,349,056, 10.8.20. Appl., 22.3.19.

A small container open at the top is arranged centrally within a reservoir near the top. The container accommodates two filtering bags, each of which is hinged at one side to the side of the container, the two hinges being on opposite sides. Each bag may be swung in a vertical plane, so that it is suspended over the reservoir to filter the liquid which is supplied to the reservoir, and the pivots of the two bags are geared together by racks and pinions, so that when one is in use over the reservoir the other is withdrawn into its container to dry the residue formed on it.—W. F. F.

Filter. E. J. Sweetland, Assr. to United Filters Corp. U.S.P. 1,349,238, 10.8.20. Appl., 30.3.15.

A FILTER plate has the central web portion reduced in thickness to provide drainage spaces when covered with filtering fabric on both sides. The fabric is supported on a sheet of reticulated material underneath, and means, such as a clamping ring, are provided for clamping the edges of the fabric to the plate and sealing the joint. The same ring also seals the joint between two adjacent filter plates.—W. F. F.

Filtering materials. J. H. Berrigan, Assr. to H. R. Worthington. U.S.P. 1,350,292, 24.8.20. Appl., 8.12.15.

LIQUID to be filtered is supplied to the interior of a casing and the filtered liquid is discharged from the interior of a hollow element having walls of filtering cloth supported in the casing. A hot fluid is continuously supplied to the interior of the filtering element during the filtering operation.

—W. F. F.

Filter. F. K. and E. F. Atkins. U.S.P. 1,350,433, 24.8.20. Appl., 20.9.16.

SOLID material is deposited on the outer surface of a filter cloth supported on a flat plate. To remove the cake, liquid is forced through the cloth from the inner side so as to raise it from the surface of the plate into contact with a scraper which extends over the active surface of the cloth, the scraper and plate being movable relatively to each other. The scraper is normally out of contact with the cloth.—W. F. F.

Dryer. G. L. Spencer. U.S.P. 1,348,757, 3.8.20. Appl., 24.7.19.

A VERTICAL cylindrical casing is provided with a concentric tube, open at both ends and extending from the bottom of the casing nearly to the top. The casing is divided into two parts by a horizontal partition having openings, which are covered by receptacles containing the material to be dried. The bottom of each receptacle is perforated and an electric heater is contained in a chamber below the casing communicating with the lower end of the vertical tube. When suction is applied to the lower compartment hot air is drawn upward through the tube and then downward through the material.—W. F. F.

Dehydrating plant. L. E. Post and D. A. Riedy. U.S.P. 1,349,908, 17.8.20. Appl., 9.6.19.

THE plant comprises a series of chambers each containing a number of superposed trays, together with means for leading hot air independently to each of the chambers, and for guiding the air within the chambers. Each chamber has an air outlet near the bottom leading into a central chamber, and the central chamber has an outlet to the atmosphere.

Drying solutions; Process of—. C. L. Dean. U.S.P. 1,350,072, 17.8.20. Appl., 27.4.18.

THE liquid is sprayed into a chamber and subjected to streams of hot, dry gases which are alternately convergent and parallel.—B. M. V.

Precipitating system; Electrical —. L. W. Chubb, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,349,362, 10.8.20. Appl., 6.1.17.

A DISCHARGE electrode and a co-operating rotary collecting electrode are placed in a treating chamber in positions such that permanently active and inactive zones of the electric field extending between them are formed. Suspended particles are precipitated electrically from fluid streams flowing between the electrodes, and the particles are collected on a stream boundary.—J. W. D.

[Fractionating apparatus.] Aerial condenser. L. P. Litzinger, P. F. Conerty, and W. Snodgrass. U.S.P. 1,349,681, 17.8.20. Appl., 19.6.19.

VAPOUR passes upwards from a still to both ends of a horizontal pipe forming an expansion chamber. Other horizontal pipes of decreasing capacity are superposed one above the other, both ends of each being connected with the pipe below. All the pipes are air-cooled. The lowest condensing pipe and the highest are connected by separate valved pipes with a liquid-cooled condenser.—W. F. F.

Separating solids from liquids; Apparatus for —. H. N. Herrick. U.S.P. 1,349,881, 17.8.20. Appl., 19.2.20.

A MIXTURE of solid and liquid is rotated by a centrifugal pump having means for retaining the solid matter and discharging it separately. The solid matter is received in a casing having an outlet normally closed but capable of being opened by means within the casing.—W. F. F.

Centrifugal clarifier. A. M. del Valle. U.S.P. 1,350,009, 17.8.20. Appl., 16.8.19.

A NUMBER of rotating concentric cylindrical pans communicate with one another, and liquid is supplied to the innermost pan. Scum is removed from the surface of the liquid in each pan by scoops attached to discharge pipes, and the clarified liquid is collected from the outermost pan.—W. F. F.

Liquid and gas contact apparatus. H. J. Zimmermann, Assr. to The G. A. Buhl Co. U.S.P. 1,350,202, 17.8.20. Appl., 5.7.18.

A LIQUID spray is delivered into the centre of a gas conduit, a portion of which is obstructed by a shield surrounding the spray nozzle, and the annular portion surrounding the shield is provided with helical baffles, so that the gas has a rotary motion on reaching the spray.—B. M. V.

Conveying and treating [powdered] materials; Process and apparatus for —. G. I. Rhodes and H. V. Coes. U.S.P. 1,350,337, 24.8.20. Appl., 13.11.17.

SOLID materials which are likely to be burned or oxidised in air are conveyed by a current of gas which is air-free and inert with respect to the

material; the latter is removed from the gas after arrival at its destination.—B. M. V.

Liquefaction of permanent gases; Counter-current apparatus with internal expansion engine for —. R. Mewes. G.P. 317,757, 29.8.15.

In order to avoid a rise in temperature of the wall of the liquefaction chamber near to the expansion engine, the driving shaft of the latter is carried through the chamber, emerging at the warmer end, and is then coupled outside to the engine.

—W. J. W.

Distilling and rectifying apparatus. R. Hübner. G.P. 318,477, 20.8.18.

The still is divided into two compartments, and the running off of the spent wash from the lower compartment and the passing of steam from the lower to the upper compartment are controlled by two valves on the same vertical rod in such manner that the opening of the valve in the steam supply pipe is accompanied by closing of the valve in the run-off pipe and *vice-versa*. The wash is fed into the upper compartment, in which part of the alcohol is distilled off, and is then passed through a valved pipe into the lower compartment, whilst the heating steam is introduced into the lower compartment and then passes into the upper compartment.—J. S. G. T.

Mixing gases and liquids; Process for —. K. Morawe. G.P. 318,766, 5.1.17.

FINELY-perforated sieves are arranged one above the other to form an enclosed chamber. The gas is forced under pressure through the lower sieve-plate, and the liquid is introduced through the upper one.—W. J. W.

Separating solids or liquids from gases; Filling material for apparatus for —. R. Forster. G.P. 318,889, 29.10.18.

PIECES of metal, earthenware, porcelain, etc., shaped like screw propellers are thrown haphazard into the separating chamber, and thus form an irregular, many-sided packing material which facilitates separation of solid or liquid particles from the gases. Choking of the channels and formation of inactive spaces are avoided.

—W. J. W.

Gases; Process for purification of very hot —. W. Freytag. G.P. 319,796, 1.4.19.

The gases are passed through molten slag of low viscosity which retains the dust. A portion of the gases may be used to heat the slag. A slag furnace having one or more chambers, and with pipes dipping into the slag-bath, may be used, and the slag-bath may be provided with a siphon which allows the slag to run off without escape of the gases.

—W. J. W.

Crystal masses; Method of obtaining large — with well-formed crystals from hot concentrated liquors. E. Waskowsky. G.P. 320,315, 22.8.17. Addn. to 306,173 (J., 1918, 724 A).

To lengthen the period of cooling of the liquor, it is first sprayed upwards either vertically or at an angle, and then allowed to drop into the crystallising vessel.—W. J. W.

Concentrating liquids; Process and apparatus for —. A. Herrlich. G.P. 320,662, 24.1.19. Addn. to 315,035 (J., 1920, 356 A).

The heating plates described in the original patent are grooved radially so as to give an externally-pointed surface to the hollow heating arrangements, and thus prevent accumulation of thick liquids, which are enabled to flow outwards and pass

through openings in the plate on to the next heater. The level of the liquid on the plates is maintained by overflow apertures.—W. J. W.

Evaporation of liquids which are liable to burn, such as sulphite cellulose liquors; Apparatus for the —. C. Tittel. G.P. 322,462, 17.11.17.

TROUGHS, divided into small compartments by parallel cross partitions with openings alternately at opposite ends, are arranged side by side in step formation. Each is provided with an overflow and independently operated heating coils, so that any desired number of successive troughs can be put into operation as a single unit, and, if need be, the liquid in different stages of concentration in the individual troughs can also be handled separately.—G. F. M.

Filtration and/or percolation of liquids. C. Yeoman. U.S.P. 1,349,798, 17.8.20. Appl., 2.10.16. SEE E.P. 11,287 of 1915; J., 1916, 1251.

Furnace. M. Mathy. U.S.P. 1,349,899, 17.8.20. Appl., 26.6.19.

SEE E.P. 131,169 of 1919; J., 1920, 1 A.

Separating solid particles from air employed for carrying off said particles from machinery or processes in which they are produced or given off; Apparatus for —. T. Robinson and Son, Ltd., C. J. Robinson, and T. J. Stevenson. E.P. 149,089, 16.5.19.

Moulds for casting chemical and other sticks. T. Tucker. E.P. 149,477, 31.5.19.

Conveying or transporting goods; Apparatus for — particularly as a device for charging furnaces. A. Smallwood. E.P. 149,495, 24.6.19.

Furnace [; Boiler — for burning powdered fuel]. J. U. McDonald. U.S.P. 1,349,971, 17.8.20. Appl., 15.9.19.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Lignite from the Rhine district; Gasification of —. J. Weiss and H. Becker. Stahl u. Eisen, 1920, 46, 1067—1073.

TESTS were made in a small producer of 1 m. diam. The air blast was preheated to 70° C. and contained 0.81% CO₂ due to contamination with flue gases. The average composition of the lignite through the trial was 57.1% moisture, 27.1% C, 2.3% H, 11.0% O, N and S, and 2.5% ash. The average yield of gas was 1.6 cb. m. per kg., with 8.6% CO₂, 0.21% O₂, 23.7% CO, 1.60% CH₄, and 12.5% H₂; calorific value 1085 cals. per cub. m. With briquettes containing 15% of moisture the gas contained 3.7% CO₂, 0.3% O₂, 30.0% CO, 2.0% CH₄, and 10.1% H₂. If the gas from raw lignite is dried, it is quite as good as gas from better coals. It can be dried by cooling in spray, Theisen- or disintegrator-washers, and the tar can be recovered from the liquor. Raw lignite can also be gasified in rotary-grate producers, no steam being admitted and the fuel level being kept 25" higher than with briquettes.—A. G.

Coke-oven engineering; Recent developments in by-product —. J. Becker and F. W. Sperr. Blast Furnace and Coke Assoc., Chicago. Gas World, 1920, 73, Coking Sect., 82—85.

THE new Koppers oven is a combination, cross-regenerative oven with triangular flues, and can be operated either with producer gas or with

coke-oven gas with waste gas return, or with straight coke-oven gas. The gas mains and stack flues are all on one side of the battery; this is of importance from the point of view of cost and economy of operation. There are two coal-gas distributing flues, the upper communicating with the nozzles on the half nearest to the gas mains, while the lower flue communicates with the nozzles on the far half of the wall. There are two lower gas supply mains. One of these is for producer gas and the other for returned waste gas. The waste gas outlets at the bottom of the regenerators are so placed that the passages from the regenerators on the far side of the battery pass along the bottom of the regenerators on the near side and communicate with the stack flue. Alternate regenerators serve for air and for producer gas, or, as the case may be, for air and for returned waste gas. Thus, all of the fuel gas and returned waste gas inlets as well as all of the waste gas outlets are brought together on the same side of the battery—an arrangement which greatly favours convenience of operation. The oven is designed to have a capacity of 7.6 net tons of coal, and is of such width as to work with 12 hrs. coking time with a daily capacity of 15.2 net tons of coal, producing 150,000 cub. ft. of gas. A plant having ample gas storage capacity can be operated with two 8-hr. shifts, only the heaters and producer operators being required on the third shift.—A. G.

Gas-producer process; Addition of carbon dioxide in the —. O. Essich. *Feuerungstech.*, 1920, 8, 184—185.

IN producers operating without steam, the temperature of the exit gases can be reduced by the addition of carbon dioxide to the air-blast. By the addition of 1 cub. m. of carbon dioxide to every 5 cub. m. of oxygen the temperature can be lowered from 1000° C. to 500° C. If the carbon dioxide is added in the form of waste gases the blast has a composition of 3.5% CO₂, 17.5% O₂, and 79% N₂. With hot waste gases the carbon dioxide can be increased by 0.5% for every 100° C. increase in temperature. The economy in coal amounts to CO₂ × 100 / (CO₂ + O₂)%. The amount of carbon dioxide added must be carefully regulated in proportion to the cross-section of the chamber.—A. G.

Gas producers. K. Bunte. *J. Gasbeleucht.*, 1920, 63, 541—545.

THE advantages of heating gas retorts by means of gas from a large central gas-producer plant are discussed, and recent improvements in the construction and operation of gas producers are described.

Mineral oils; Calculation of the viscosity of a mixture of two — from the viscosities of its components. H. Schwedhelm. *Chem.-Zeit.*, 1920, 44, 638.

THE viscosity, z , of the mixture may be calculated from the formula: $z = (n-d)[(m-d)/(n-d)]^p + d$, or $(z-d) = (n-d)^{1-p} \times (m-d)^p$, where m = the viscosity of the more viscous oil, n = that of the less viscous oil, and d = a constant; $p = r/(r+q)$, r being the volume of the more viscous oil and q that of the less viscous oil.—W. P. S.

Paraffin wax; Refractometric determination of — as a control test in the manufacturing process. M. Freund and G. Palik. *Petroleum*, 1920, 15, 757—758. *Chem. Zentr.*, 1920, 91, II., 816.

THE proportion of paraffin wax, x , may be calculated from the refractive index (n_3) of a mixture of paraffin wax and a filtrate oil, if the respective coefficients (n_2) and (n_1) are known: $x = (100n_3 - 100n_2) / (n_1 - n_2)$ and, conversely, the refractive index of the mixture may be calculated when the % of

paraffin wax is known: $n_3 = [xn_2 - (100-x)n_1] / 100$. The formulæ are only applicable when the sp. grs. of the constituents are practically the same. The results are lower than those obtained by the methods of Holde or Neustadt.—C. A. M.

Bituminous acid-proof coatings. See XIII.

PATENTS.

Peat; Treatment of —. M. C. Olsson. E.P. 147,286, 16.4.19.

RAW peat is partly dehydrated at ordinary temperature, and is then subjected to violent ebullition of the contained water by means of rapid lowering of pressure whilst the peat is being heated. The water can then be extracted by pressing or by other means.—A. E. D.

Furnace retorts. C. H. Smith. E.P. 123,739, 17.2.19. *Conv.*, 18.2.18.

A HORIZONTAL retort for carbonising coal is heated by longitudinal flues in the walls which are built up of hollow tiles. The coal is moved continuously through the retort by two conveyors mounted on parallel horizontal shafts and carrying blades which overlap. The retort is made inverted heart shape in cross section to accommodate the conveyors. The retort walls are constructed of carborundum or a material containing it, and are surrounded in succession by a layer of fire-brick, a layer of a diatomaceous earth brick known as "sigur" brick, and finally by a metal casing. A layer of asbestos is placed between the bricks and the metal casing in the upper part to allow for expansion. The conveyor shafts are journaled in removable covers which are sufficiently large to allow the removal of the conveyors. The conveyor shafts are hollow and are made in sections secured by spigot and socket joints which are locked by the conveyor blades passing through both parts.—W. F. F.

Coal gas; Manufacture of — and recovery of tar. H. Geyer. G.P. 319,523, 6.5.19.

NITROGEN-FREE heating gases, obtained by introducing a mixture of oxygen and steam into red-hot coke, are mixed with cold tar-free coal gas in a vessel directly connected with the rotary distillation retort. By this means the heating gases are cooled to the necessary temperature for the distillation retort, without the necessity of adding so much steam as to cause deterioration of the coal gas produced in the retort.—C. A. M.

Coal; Process for distillation and gasification of —. T. Limberg. G.P. 322,646, 28.10.17. *Addn.* to 303,954 (J., 1920, 441 A).

THE process described in the original patent may be carried out without the use of reduced pressure and with a single receiver for the distillation products. The devices for heating and for drawing off the products pass through the wall of the retort and are provided with openings for cleaning purposes. The removal of the tar vapours without decomposition is rapidly effected by the steam which is present.—W. J. W.

Hydrocarbon gas; Method of making —. D. and R. F. Macdonald. E.P. 146,560, 8.3.19.

COMBUSTIBLE gas (consisting largely of acetylene) is produced by creating an arc between carbon electrodes immersed in water.—A. E. D.

Gases; Apparatus for purifying —. H. F. Smith, Assr. to The Smith Gas Engineering Co. U.S.P. 1,348,966, 10.8.20. *Appl.*, 5.7.18.

A HOUSING is provided with a hollow rotating pad, so placed that the gas inlet and outlet openings of the housing are adapted to communicate, one

with the space inside and the other with the space outside the pad.—A. G.

Coal-gas; Process and apparatus for recovering the ammonia content of —. B. Torrey, jun., Assr. to Semet-Solway Co. U.S.P. 1,319,393, 10.8.20. Appl., 3.5.18.

THE water in the hydraulic main is heated by the sensible heat of the crude gas which is subsequently washed and cooled to remove tar and fixed ammonia. The gas is then reheated by washing it with the heated water from the main and is passed through a bath of sulphuric acid to recover the ammonia as sulphate.—A. G.

Motor fuel for aeroplanes and other motors. U.S. Industrial Alcohol Co., Assces. to F. W. T. Schreiber. E.P. 128,915, 16.6.19. Conv., 25.6.18.

AN alcohol, an aromatic hydrocarbon, and at least 4% of an ether are blended, e.g., 30 pts. by vol. of benzol, 30 of gasoline or naphtha, and 5 of ether. —A. E. D.

Hydrocarbons; Treatment of —. G. F. Forwood and J. G. Taplay. E.P. 145,198, 16.4. and 7.7.19.

PETROLEUM or coal tar distillates are passed together with steam over carbon heated to a specified temperature, e.g. for kerosene to 600°—630° C. and for heavy fuel oil to 850°—950° C., in order to obtain lower-boiling products.—A. E. D.

Petroleum oils; Purification of —. J. J. Hood. E.P. 145,818, 24.2.19.

THE vaporised oil is brought in contact with heated alumina, bauxite, or magnesite, so that the sulphur compounds present in the oil are dissociated and hydrogen sulphide is formed therefrom. The hydrogen sulphide is subsequently absorbed. —A. E. D.

[Mineral] oil; Refining — by distillation. C. B. Forward. E.P. 145,894, 5.4.19.

PREHEATED oil is conveyed through a series of sets of heaters, supplied with superheated steam, which is used repeatedly in the successive heaters after periodic reheating. The steam discharged from the final heater of each set is used for atomising the heated oil in a separator, the volatile products from which are condensed.—A. E. D.

Liquid fuel from petroleum; Manufacture of —. H. Wade. From Standard Oil Co. E.P. 147,353, 21.7.19.

CRUDE petroleum is distilled by direct fire and superheated steam (or inert gas) until high melting pitch is left (e.g., of m.p. 192° F.), and the pitch is then fluxed with low viscosity oil.—A. E. D.

Petroleum hydrocarbons; Process for treating —. T. T. Gray. U.S.P. 1,340,889, 25.5.20. Appl., 18.5.14.

VAPORISED oil is refined by passing it through heated fuller's earth.—A. E. D.

"Gas-oil"; Making —. C. Ellis, Assr. to Ellis-Foster Co. U.S.P. 1,311,975, 1.6.20. Appl., 29.5.13.

GASOLINE-LIKE material is made by mixing petroleum vapour and gaseous petroleum decomposition products and subjecting the mixture to several atmospheres pressure and a decomposition temperature. The yields of heavier and lighter products are thereby increased.—A. E. D.

Petroleum oils; Distillation of —. R. E. Humphreys and W. M. Burton, Assrs. to Standard Oil Co. U.S.P. 1,343,674, 15.6.20. Appl., 28.11.16.

OIL is distilled under 75 lb. pressure, the vapours being cooled under the same pressure, in such a way

that all insufficiently cracked material is returned to the still.—A. E. D.

Hydrocarbons; Process of treating —. L. W. McOmber, Assr. to C. B. Belknap. U.S.P. 1,345,452, 6.7.20. Appl., 24.2.16.

OIL is heated to 60 lb. pressure and then subjected to condensing action at a still higher pressure. —A. E. D.

Light hydrocarbons; Apparatus for producing —. J. A. Yunc. U.S.P. 1,345,656, 6.7.20. Appl., 15.10.18.

IS the cracking of crude oil or residues electric heating is made use of both for the pressure still and the vapour space.—A. E. D.

Petroleum; Process of distilling —. P. M. Bid-dison and H. T. Boyd. U.S.P. 1,345,740, 6.7.20. Appl., 15.2.18.

HIGH-BOILING oil is circulated to and from a bulk supply, and heat and pressure are supplied. The vapours are passed into an auxiliary condenser which returns uncracked material. The uncondensed vapours are cooled and the gas stripped. The heating is provided by a current of highly-heated gas.—A. E. D.

Hydrocarbon oils; Apparatus and process for the conversion [cracking] of —. V. L. Emerson. U.S.P. (a) 1,346,797, and (b) 1,346,798, 13.7.20. Appl., 6.5.20.

(A) GASEOUS products of distillation from a pressure still are submitted to impact, and the products are returned to the oil in the still. (b) Kinetic energy is imparted to oil which is "subjected to impact," as are the resulting products, which ultimately are intimately mixed with fresh oil and the gaseous products withdrawn.—A. E. D.

Petroleum; Apparatus for cracking —. Method of treating hydrocarbons. H. W. Jones, F. E. Jones, Administrator, Assr. to Kansas City Gasoline Co. U.S.P. (a) 1,347,543 and (b) 1,347,544, 27.7.20. Appl., 13.2.18.

(A) THE plant consists of a number of small, separately fired cracking stills, compressors, tanks, and condensing system. (b) The oil is compressed and forced into separately heated cracking zones. The cracked products are discharged separately, collected together, and condensed.—A. E. D.

[Mineral] oil-refining apparatus. F. E. Wellman, Assr. to Kansas City Gasoline Co. U.S.P. 1,347,567, 27.7.20. Appl., 1.8.16.

OIL under pressure is caused to expand into a cracking coil of larger bore, which is connected with a condenser having a control valve.—A. E. D.

Cracking hydrocarbons; Method of —. F. E. Wellman, Assr. to Kansas City Gasoline Co. U.S.P. 1,347,568, 27.7.20. Appl., 12.2.19.

A HYDROCARBON oil is heated at a high temperature and pressure in a still; the oil occupies 10% of the still volume, the remainder being filled with gas under pressure, which is retained in the still when the treated oil is removed.—A. E. D.

[Mineral] oil; Method of refining —. F. E. Wellman, Assr. to Kansas City Gasoline Co. U.S.P. 1,347,664, 27.7.20. Appl., 30.3.18.

INTERMITTENT and equal charges of oil are heated under pressure, and the vapours are severally condensed under pressure.—A. E. D.

Cracking hydrocarbons; Apparatus for and art of —. J. W. Coast, jun., Assr. to The Process Co. U.S.P. (A to E) 1,348,264-8, 3.8.20. Appl. (A,B) 22.3.17, (C) 27.3.17, (D) 9.4.17, and (E) 16.4.17.

(A) THE usual pressure still has one end protected against direct heat. Reflux condensed liquid is conducted towards the protected end. (B) The two ends of the pressure still are protected against direct heat. The condensed product is conducted by a branched pipe through the still contents and deposited on the cool end portions of the still. (C) A series of pressure stills at different levels communicate with one another so that pressure is equalised and oil flows from one to the other through a coke trap. (D) Refluxing of uncracked oil is effected by maintaining the top of the still in a relatively cool condition and deflecting vapour to the end and along the cool upper surface. (E) Refluxing of uncracked oil is effected by a baffling device located near the top of the still so as to provide a narrow passage-way. The baffle is an inverted trough with its sides dipping into the heated oil.—A. E. D.

[Hydrocarbon] oils; Process and apparatus for continuously cracking —. W. B. Price and E. Dietz. U.S.P. 1,349,294, 10.8.20. Appl., 6.7.16.

A CONTINUOUS stream of a heavy hydrocarbon oil is passed through an apparatus in which successive portions of the oil are subjected simultaneously to progressively higher temperatures and pressures. The light hydrocarbons are removed as they are formed.—L. A. C.

Paraffin wax; Separation of — from the neutral oil and the oxygen-containing constituent of producer or low-temperature tar. Allgem. Ges. für Chem. Ind. m.b.H. G.P. 319,656, 19.3.18.

PARAFFIN wax is separated from the heavy oil by fractional precipitation with pyridine or pyridine bases and water, especially in the cold. The remainder of the paraffin wax may then be obtained by treating the liquid with more pyridine or by diluting it with water, and then by filtration and further dilution the neutral oil (i.e., the portion insoluble in alkali) is obtained.—C. A. M.

Shale and other bituminous minerals; Production of oil from —. Zeller und Gmelin. G.P. 321,870, 23.8.18.

IN the distillation of shale in externally heated rotary retorts, with simultaneous introduction of steam or other gases free from oxygen, the strongly superheated steam or other gases are introduced at a temperature about 50° C. higher than that of the material in the retort.—J. H. L.

Distillation-gases of coal; Purification of —. E. Ciselet and C. Deguide. U.S.P. 1,349,750, 17.8.20. Appl. 6.7.15.

SEE G.P. 297,101 of 1915; J., 1917, 637.

Lubricating oils; Process of manufacturing —. H. Klever, L. C. Lautenschläger, and O. H. Göhring, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,350,814, 24.8.20. Appl., 14.2.16.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Recovery of alcohol etc. Mariller. See XVIII.

PATENTS.

Coal and other materials capable of being distilled, vaporised, or decomposed by heat; Treatment of —. Dressler Tunnel Ovens, Ltd., and C. Dressler. E.P. 149,086, 14.5.19.

COAL, peat, or the like is fractionally distilled in a horizontal oven, which is heated to varying temperatures along its length by combustion flues at the sides. The coal is passed through the oven in trucks. Transverse walls project downwards from the roof to a height just sufficient to allow clearance for the trucks, thus forming a series of pockets along the roof. The fractional distillates are withdrawn from these pockets.—W. F. F.

Distilling apparatus; Rotary dry —. F. G. Ten Broeck and M. T. Weston, Assrs. to West Virginia Pulp and Paper Co. U.S.P. 1,350,627, 24.8.20. Appl., 6.8.18.

MATERIAL is fed from a hopper into one end of a horizontal conduit containing a helical conveyor, and delivered from the other end into one end of a horizontal rotating retort. The conveyor conduit is mounted in a part of the head of the retort, which can be rotated relatively to the remainder of the retort, and which also contains the vapour-discharge passage. The outlet of the hopper is provided with a controlling gate, which is interconnected with the controlling switch of the electric motor driving the conveyor, so that the speed of the conveyor is automatically reduced as the outlet of the hopper is restricted.—W. F. F.

Incandescence lamp bulbs or the like; Methods for forming conducting seals for —. T. Yanai, Assr. to Nihon Denki Kogyo Kabushiki Kaisha. U.S.P. 1,350,907, 24.8.20. Appl., 30.9.16.

SEE E.P. 103,648 of 1917; J., 1918, 84 A.

III.—TAR AND TAR PRODUCTS.

Phenol; Determination of — in the presence of certain other phenols. R. M. Chapin. J. Ind. Eng. Chem., 1920, 12, 771-775.

A COLORIMETRIC method is described depending on the red coloration yielded by Millon's reagent with phenol but not with other phenols. The reagent is prepared by dissolving 2 c.c. of mercury in 20 c.c. of concentrated nitric acid, diluting the solution to 35 c.c., adding a few drops of nitric acid if basic salt separates out, and then adding 10% sodium hydroxide solution until the precipitate first formed no longer re-dissolves but disperses to a permanent turbidity; a mixture of 0.2 c.c. of concentrated nitric acid and 4.8 c.c. of water is then added and the solution mixed. Four c.c. of a solution containing 0.1% of total phenols is measured into each of two test-tubes and to one is added about one-half of the amount of phenol believed to be already present; the two solutions are diluted to 6 c.c., treated with 5 c.c. of Millon's reagent and heated at 100° C. for 30 mins. In this time the colour due to the phenol is developed fully whilst the red colour at first produced by other phenols is discharged or changed to yellow. The two tubes are then placed in cold water for 10 mins., their contents acidified with a mixture of 0.2 c.c. of concentrated nitric acid and 4.8 c.c. of water, diluted to 25 c.c., filtered after 10 mins., and the colorations of the filtrates compared in a colorimeter. The standard Duboscq colorimeter was used. The quantity of phenol, P, is calculated by the formula

$P = 1/(1 - I)[pR/(S - R) - IT]$ where p is the amount of added phenol, S the reading of the test solution, R that of the stronger solution, I the relative intensity of the colour yielded by other phenols as compared with that of phenol (I has a mean value of 0.007), and T the total quantity of phenols. The red colour given by phenol may be changed to yellow by treatment, under suitable conditions, with formaldehyde without any marked effect on the yellow colour present originally, and this modification of the method is recommended for the determination of small proportions of phenol. Results of experiments with a considerable number of phenols are given; only two substances, salicylic acid and β -naphthol, invalidate the test, the former giving a deep red coloration and the latter a dark brown.—W. P. S.

Bituminous acid-proof coatings. See XIII.

PATENTS.

Benzol hydrocarbons of coke-oven gas; Recovery of — from the washing oil. A. Hartmann. G.P. 298,823, 14.11.13.

BENZENE hydrocarbons are distilled from the washing oil by means of indirect steam at the ordinary pressure with the aid of a vacuum. The presence of the higher benzene hydrocarbons, which are simultaneously condensed, causes a reduction of the vapour pressure below that of the constituent of lowest b.p.—C. A. M.

Hydrocarbons; Production of liquid — from naphthalene. F. Fischer. G.P. 299,131, 22.12.15.

A MIXTURE of naphthalene and aluminium chloride is heated under pressure to above the normal boiling point of naphthalene; e.g., by employing 4% of aluminium chloride and a temperature of 330° C. one-third of the naphthalene is converted to liquid hydrocarbons, mainly di- and tetrahydronaphthalene, and the remainder forms a mixture of pitch and a coal-like product.—L. A. C.

Tar oils; Agents for dissolving, separating and extracting the solid constituents of —. Tetralin G. m. b. H. G.P. 301,651, 23.4.16.

HYDRONAPHTHALENES are used alone or in combination with other substances. In particular, tetrahydronaphthalene and higher hydrogenised products dissolve considerable quantities of naphthalene at 30° C. and unlimited quantities at higher temperatures.—J. H. L.

SEE also pp. (A) 651, *Hydrocarbons* (E.P. 145,198); 652, *Paraffin wax* (G.P. 319,656); 665, *Paint* (G.P. 318,699), *Solvent* (G.P. 320,807), *Varnish* (G.P. 320,808); 675, *Aldehydes and ketones* (G.P. 321,567); 676, *Nitro-compounds* (G.P. 299,015).

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Dye; Alkali proof — and method of producing the same. L. C. Cates, Assr. to Sunbeam Chemical Co. U.S.P. 1,349,265, 10.8.20. Appl., 27.7.18.

AN excess of a saponifiable oil is added to a boiling solution of a non-alkali-proof dye in $N/4$ sodium hydroxide, and the reaction is allowed to continue until the alkali is exhausted. Sufficient alkali is then added to saponify the excess oil, and the product, after it has hardened, is powdered.

—L. A. C.

Solvent for dyestuffs. G.P. 320,807. See XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Paper makers' quicklime and hydrated lime; Specifications for —. U.S. Bureau of Standards, Circ. 96, 15.6.20.

THE specifications given have been approved by the National Lime Association and the Technical Association of the Pulp and Paper Industry (U.S.A.). The percentage compositions specified are:—Quicklime: CaO, 95 (min.); MgO, 2 (max.); insol. matter, including SiO_2 , Fe_2O_3 , and Al_2O_3 , 2 (max.); CO_2 , 2 (max.). Hydrated lime: CaO, 72 (min.); MgO, 1.6 (max.); insol. matter, including SiO_2 , Fe_2O_3 , and Al_2O_3 , 1.6 (max.); CO_2 , 1.6 (max.). For analytical methods reference is made to U.S. Geological Survey, Bull. 700 (Hillebrand, Analysis of silicate and carbonate rocks).

PATENTS.

Fibrous vegetable material [Spanish moss]; Process of treating — and the resulting product. G. S. McDaniel, Assr. to E. H. Kimbell. U.S.P. 1,350,031, 17.8.20. Appl., 24.7.19.

GREEN, partly cured, or cured Spanish moss is treated with an alkaline solution of definite strength, whereby the outer coating shrinks upon the inner fibres.—A. J. H.

Fibres; Process for treating —. J. H. Pickup, Assr. to G. A. Wilson. U.S.P. 1,350,621, 24.8.20. Appl., 19.3.19.

VEGETABLE fibre is prepared for spinning by allowing it to ferment in a hot bath for a considerable time, boiling it under pressure in lime water, and then subjecting it alternately to acid and alkaline baths.—W. F. F.

Pyroxylin sheet of low inflammability. J. G. Jarvis. U.S.P. 1,349,156, 10.8.20. Appl., 13.3.19.

THE material is composed of cellulose acetate, acetone, and cinchonine and its salts.—W. F. F.

Parchment paper; Manufacture of —. P. Hoering. G.P. 303,266, 1.9.16.

THE leaves, or stalks, or both, of the reed mace are subjected to the action of caustic alkalis under pressure, and the product after washing is employed as paper pulp without any special beating and without sizing. The material consisting of bast fibres and parenchyma, furnishes a transparent, grease-proof paper of a brownish-yellow colour.—G. F. M.

Cardboard [paper and paper fabrics]; Process for rendering — grease- and waterproof. L. Buchbinder. G.P. 316,527, 19.3.19. Addition to 306,028.

CARDBOARD which has been coated with a glue precipitate containing a filling material, in accordance with the chief patent (J., 1918, 575 A), and dried, is further coated with a mixture consisting of a saturated solution of tannin in spirit and a varnish containing a drier, to which mixture zinc white and formaldehyde have been added.—J. H. L.

Paper, pulps, paper yarns and fabrics; Sizing and waterproofing of —. E. Fues and E. Braumüller. G.P. 318,923, 3.1.17.

THE paper material is treated with colloids such as dialysed solutions of hydroxides of trivalent metals, preferably iron or chromium, with or without the addition of solutions of other, preferably organic, colloids.—C. A. M.

Paper, fabrics and the like; Sizing, waterproofing, dressing, etc. —. W. Schmidt and E. Heuser. G.P. 321,232, 15.3.18. Addn. to 296,124.

THE paper pulp or fabric is treated with a solution

of tar soap prepared by saponification of wood-, lignite-, or coal-tar, previously extracted with water. Injurious acid substances may be removed from the tar by distillation, and a soap prepared by incomplete saponification of the tar may be used.—J. H. L.

Paper; Removal of ink from writing —. H. Gethe. G.P. 321,545, 26.7.19.

THE paper is passed through four consecutive baths, of which the first and third contain oxalic acid, the second potassium permanganate, and the fourth aluminium sulphate; it is afterwards passed between hot rollers.—J. H. L.

Straw; Utilisation of the waste lyes from the alkaline digestion of —. S. Herzberg. G.P. 319,068, 13.11.17.

ALKALINE lyes from the treatment of straw are electrolysed to obtain the caustic soda in a concentration suitable for further use. The degree of evolution of oxygen or of oxidation of organic substances at the anode varies with the strength of the current.—C. A. M.

Straw; Utilisation of waste liquors obtained in the digestion of —. S. Herzberg. G.P. 321,453, 28.3.19. Addn. to 319,068 (preceding).

THE liquor, or at least the portion to be used as anodic bath, is treated in the cold with mineral acid or bisulphate and heated to 70° C.; it is then filtered from precipitated organic substances and electrolysed. The precipitated lignic acid can be utilised, and if common salt solution is used as anodic electrolyte the chlorine produced may be employed in the dissolution of chopped straw previously treated with milk of lime.—J. H. L.

Waste liquors; Purification of alkaline — contaminated and coloured with organic impurities. F. Küttner, E. Profeld, and E. Sidler. G.P. 322,461, 8.7.19.

WASTE liquors from the mercerisation process and viscose manufacture are concentrated and simultaneously oxidised in open vessels, whereby the hemicellulose is converted into insoluble oxycellulose. The oxidation may be carried out by injecting air into the liquors or by the addition of alkali nitrate.—G. F. M.

Paper making. Great Northern Paper Co., Assees. of C. E. Pope. E.P. 136,839, 18.12.19. Conv., 14.3.18.

SEE U.S.P. 1,279,756 of 1918; J., 1918, 764 A.

Alkyl ethers of starches and similar carbohydrates and method of producing the same. L. Lilienfeld. Assr. to The Chemical Foundation, Inc. U.S.P. 1,350,820, 24.8.20. Appl., 16.2.14.

SEE F.P. 468,162 of 1914; J., 1914, 958.

Paper-making machines. A. Wood and G. Russell. E.P. 149,359, 21.12.17.

Paper, cardboard, and the like; Machines for manufacture of —. L. Thiry. E.P. 149,416, 10.5.19.

Evaporation of sulphite-cellulose liquors. G.P. 322,462. See I.

Fat from sulphite-cellulose lyes. G.P. 305,091. See XII.

Paint. G.P. 320,011. See XIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Vegetable fibres; Process for treating —. Gillet et Fils, Assees. of C. Schwartz. E.P. 136,569, 12.12.19. Conv., 13.12.18. (Cf. E.P. 136,568 and 144,204; J., 1920, 513 A, 542 A.)

WOOL-LIKE characteristics can be imparted to vegetable fibres by simple immersion in nitric acid (65–75%) for not more than half an hour, followed by washing with water. The fibres may be treated in any stage of their preparation and the temperature should be less than 20° C. If nitric acid stronger than 75% be used, the treatment must be carried out more quickly. Print effects may be produced directly or by means of reserves. The fibres so treated increase in weight.—A. J. H.

[Azo] dyestuffs containing the sulphonamide group; Application of — to dyeing and printing. J. W. McMyen. E.P. 149,428, 13.5.19.

Azo dyes which contain a sulphonamide or substituted sulphonamide group are soluble only in strong alkalis from which they are easily precipitated by weak acids, alum, ammonium chloride, bicarbonates, and carbon dioxide. Cloth is dyed by impregnation with a solution of the dye in caustic soda, squeezing, drying, treatment in a fixing bath containing one of the above precipitants, rinsing, and drying. Cloth is printed with a paste containing the dye dissolved in caustic soda and thickened with starch, then dried, and fixed in an alum bath. The addition of aluminium salts to the printing paste increases the brightness and fastness. Suitable scarlet, red and light red dyes are formed respectively from β -naphthol and diazotised 2-aminotoluene-4-sulphonamide; 2-aminotoluene-4-sulphonanilide; *o*-, *m*-, *p*-aminophenylsulphonamides. They can be used for discharges or resists with Aniline Black. 2-Aminotoluene-4-sulphonamide coupled with diazotised *m*-phenylenediamine gives an orange dye.—A. J. H.

Dyeing-machine. W. A. Ainsworth. U.S.P. 1,318,974, 10.8.20. Appl., 19.1.20.

A ROTATING roller covered with an absorbent material is fitted in a reservoir for colouring matter, and projects above the top of the reservoir. Thread, yarn, or the like passes over the reservoir and is intermittently brought in contact with the absorbent material on the roller.—L. A. C.

Dyeing-machine. E. Schnurrenberger. U.S.P. 1,350,740, 24.8.20. Appl., 9.1.20.

A MACHINE for the treatment of skeins with liquids consists of a liquor container, and means for suspending a skein in, and causing it to trail through the liquor, including a skein-trailing member movable in one plane.—A. J. H.

Dyeing [Sulphur Black]. C. S. Althouse. U.S.P. 1,349,867, 17.8.20. Appl., 24.6.20.

IN dyeing goods with Sulphur Black, magnesium sulphate is used in the softening bath.—A. J. H.

Leuco-compounds of vat-dyes; Preparation of — suitable for dyeing wool. L. Cassella und Co. G.m.b.H. G.P. 321,119, 16.11.15.

THE leuco-compound is prepared in the presence of a higher alcohol which can be salted out of aqueous solution, and it is thereby separated simultaneously with the alcohol. An example is given of the reduction of Thioindigo-Red B with sodium hydroxide and hydrosulphite, with the addition of isobutyl alcohol.—G. F. M.

Aniline Black; Production of — upon vegetable textile fibres. E. A. Fourneauux. U.S.P. 1,350,600, 21.8.20. Appl. 18.1.18.

SEE E.P. 117,987 of 1917; J., 1918, 576 A.

Waste liquors. G.P. 322,461. See V.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid manufacture; Use of sodium nitrate solution in the lead chambers in —. H. Lemaître. Monit. Scient., 1920, 10, 145–157.

THE continuous introduction of sodium nitrate in solution through the Glover tower produces saturation of the acid with sodium bisulphate and consequent choking of pipes. Dilution of the Glover acid with chamber acid to prevent saturation is rendered impracticable by the limited concentration capacity of the Glover. Alternate introduction of nitric acid and sodium nitrate may be suitable provided that the supply of nitrate is arrested before saturation is reached, this stage being determined by calculation or by control analysis of the bisulphate content of the acid. To avoid saturation entirely, it is preferable to introduce the nitre as a mixture of nitric acid (36° B., sp. gr. 1.33) and sodium nitrate solution. Loss of nitric acid resulting from imperfect working of the Glover seldom exceeds 5–10%; in the Gay-Lussac tower it amounts to 50–75% of the total, but these losses may be considerably reduced, and the economy achieved may equal or exceed that attained by use of sodium nitrate. The reactions which take place in the Gay-Lussac towers are indicated by the author, and the control of the chamber process by the use of graphs is advised.—W. J. W.

Nitric acid; Production of concentrated — from nitrous vapours. M. Kaltenbach. Chim. et Ind., 1920, 4, 576–590.

AFTER a preliminary survey of the reactions involved and the conditions necessary for the conversion into nitric acid of nitrogen oxides derived from the ammonia oxidation process, a plant is described for the production of 10 tons of nitric acid per 24 hrs. The hot gases are first passed through a pre-concentration tower fed with weak nitric acid (45% HNO₃) in which the gases are cooled and at the same time a concentration of the weak acid is effected. The removal of the water vapour from the gases takes place in externally cooled towers, which the gases leave at 30° C., then passing into a tower in which oxidation and polymerisation of nitrogen peroxide are brought about. After traversing a series of absorbing and regenerating towers, an outflowing acid of 60% HNO₃ is obtained. Concentration of this weak acid is carried out in denitrating towers with the aid of sulphuric acid, an important economy of the latter being effected by a preliminary heating of the nitric acid and its introduction in the form of vapour, by which means the necessity for steam injection is avoided.—W. J. W.

Ammonia; Synthesis of — at very high pressures. G. Claude. Chim. et Ind., 1920, 4, 5–16.

THE author recapitulates the advantages claimed for the employment of pressures up to 1000 atm.: diminution in size of contact chamber and reduction of number of times of passage of the reacting gases, increased yields of ammonia per 0.5 g. of catalyst, easy condensation of the ammonia and consequent elimination of absorption by water, and realisation of the auto-reaction even in small plants by the enormous heat developed. (Cf. J., 1919, 885 A; 1920, 61 A, 187 A.) Tightness of the joints

presents no greater difficulty at 1000 than at 100 atm. and may be more easily secured on account of their smaller size. Cupped leather packings have been employed successfully in the compressors. With high pressures loss of heat is reduced and the cost of plant erection and maintenance is smaller. Coke-oven gas appears to be a promising source of hydrogen. A plant dealing with 300 tons of coke per day yields 100,000 cub. m. of gas containing 45% hydrogen, of which 30,000 cub. m. can be extracted and utilised to fix 10 tons of nitrogen per 24 hrs.—W. J. W.

Phosphotungstic and phosphomolybdic acids. H. Wu. J. Biol. Chem., 1920, 43, 189–220.

THESE compounds belong to two distinct series, represented by P₂O₅.18XO₃ and P₂O₅.21XO₃. The properties and preparation of these acids and other members of these complex groups are described fully. (Cf. J.C.S., Oct.)—J. C. D.

Potash alum; Analysis of —. A. Harvey. J. Soc. Leather Trades' Chem., 1920, 4, 219–220.

SAMPLES of pure potash alum mixed with known amounts of iron sulphide and analysed by the method proposed by Codwise (J., 1920, 416 A) did not give theoretical results. The iron impurities are included in the titration.—D. W.

Acid clay [fuller's earth]; Acidity of Japanese —. K. Kobayashi. J. Chem. Ind. Tokyo, 1920, 23, 543–549.

JAPANESE acid clay (fuller's earth) is regarded as being a mixture of colloidal hydrous aluminium silicates, Al₂O₃.2SiO₂.xH₂O, and an amorphous compound of orthosilicic acid, SiO₂.xH₂O, and may be expressed by the formula: Al₂O₃.6SiO₂.xH₂O, where x is more than 6. The clay itself is not a true acid substance, and the acidity is to be ascribed to its adsorptive property. On adding the clay to a solution of a basic dye (R.Cl) hydroxyl ions are adsorbed from the solution and hydrogen ions are liberated and unite with the chlorine ions of the basic dye to form hydrochloric acid. Reaction between an acid clay and neutral potassium chloride solution similarly produces hydrochloric acid, which dissolves alumina from the clay. The aluminium chloride thus formed will be decomposed by hydrolysis into aluminium hydroxide and hydrochloric acid.—K. K.

Potassium plumbite; Oxidation of — to potassium plumbate by alternating current. F. Jirza. Z. physik. Chem., 1920, 94, 1–5.

POTASSIUM plumbite is the only product of the electrolysis of N/1 potassium hydroxide solution between lead electrodes by an alternating current of 49 periods. The solution of plumbite is oxidised to plumbate by a similar current if electrodes of copper, silver, gold, cadmium, magnesium, mercury, nickel, iron, platinum, or palladium are used, but there is no oxidation if the electrodes are of lead, bismuth, cobalt, thallium, or carbon. A number of other factors also play a part in the plumbate formation.—J. F. S.

Arsenic; Electrometric titration of —. C. S. Robinson and O. B. Winter. J. Ind. Eng. Chem., 1920, 12, 775–778.

IN certain coloured solutions the electrometric titration of arsenious acid is to be preferred to the ordinary method. The titration is made with iodine solution in the presence of excess of sodium bicarbonate, a mechanical stirrer is used, and the end-point is indicated by the change in direction of the swing of a beam of light from a reflecting galvanometer. Arsenic acid is titrated at 90° C. in 50% sulphuric acid solution with sodium iodide solution.—W. P. S.

Copper hydroxide; Formation and behaviour of —. V. Kohlschütter and J. L. Tüscher. Z. anorg. Chem., 1920, 111, 193–236.

THE authors describe experiments on the formation of copper hydroxide by precipitation, the pseudomorphic transformation of solid copper salts into hydroxide by the action of sodium hydroxide solution, the processes occurring at copper anodes in sodium hydroxide solution, and the formation of colloidal copper hydroxide or oxide by "discharge electrolysis" (J., 1919, 911A). It is concluded that the dehydration of copper hydroxide is due to an internal neutralisation and is to be represented by the equations $\text{Cu}(\text{OH})_2 \rightleftharpoons \text{Cu}'' + 2\text{OH}'$, $\text{CuH}_2\text{O}_2 \rightleftharpoons \text{CuO}''_2 + 2\text{H}'$, $2\text{H}' + 2\text{OH}' \rightleftharpoons 2\text{H}_2\text{O}$ and $\text{CuO}''_2 + \text{Cu}'' = 2\text{CuO}$. It is, however, not simple $\text{Cu}(\text{OH})_2$ molecules that are involved in the reaction, but molecular complexes of colloidal dimensions, the degree of dispersity, and hence the reactivity of which vary with the conditions of formation.—J. F. S.

Hydrogen peroxide; Rate of decomposition of — in the presence of iron ions. J. von Bertalan. Z. physik. Chem., 1920, 95, 328–348.

THE decomposition of hydrogen peroxide in the presence of ferrous sulphate or ferric sulphate at 40° C. is in accordance with a unimolecular catalytic equation. The state of oxidation of the iron makes no difference to the reaction, which depends on the total quantity of iron present.—J. F. S.

Colloidal sulphur. P. Bary. Comptes rend., 1920, 171, 433–435.

USING Odén's results (Nova Acta Upsala, 1913, 3 [4]) on the viscosity of suspensions of sulphur at different concentrations and temperatures, the author has calculated the mean coefficients of swelling of the granules, the results indicating that such suspensions are hydrophilic colloids. When the swelling, due to the absorption of water, becomes small the granules lose their transparency, and the liquid becomes milky and loses its stability. This absorption is favoured by the presence in solution of small amounts of salts of univalent metals and is checked by salts of divalent metals.—W. G.

Thermodynamics; Applications of chemical —. G. Urbain. Chim. et Ind., 1920, 4, 31–42.

THE author discusses the rôle played by thermodynamics in various branches of chemical industry. The application of the phase rule to saturated solutions is considered, especially with respect to the extraction of salts from carnallite. Carnot's principle of reversibility is illustrated in the case of the manufacture of hydrogen by the action of iron on water, and the contact process of sulphuric acid manufacture is also discussed from the thermodynamic standpoint. The laws of mass action and of displacement of equilibrium are among others examined in their relation to industrial applications.—W. J. W.

Quicklime and hydrated lime. See V.

Bituminous acid-proof coatings. See XIII.

Cyanogen chloride. Reed. See XIXB.

Phosphoric acid. Kleinmann and Feigl. See XXIII.

PATENTS.

Sulphuric acid; Apparatus with rectifying column for the concentration of —. H. Pauling. G.P. 299,774, 25.8.15.

A VESSEL of cast iron or an alloy thereof is used. The acid to be concentrated is fed into the top of the column. It passes from the column to the heating vessel by way of a separate vessel with overflow device so that acid cannot pass back from the heater to the column; and is at this point strong

enough to act only slightly on the material of the heater.—C. I.

Retorts for decomposition of sodium or potassium nitrate. Farbenfabriken vorm. F. Bayer und Co. G.P. 301,702, 19.4.17.

By connecting a series of retorts by means of pipes to equalise the pressures and charging the retorts at regular intervals, uniformity of the process is ensured.—W. J. W.

Nitrous gases; Process for the absorption of —. J. L. la Cour, Assr. to Norsk Hydro-Elektrisk Kvaelfstøfaktieselskab. U.S.P. 1,348,227, 3.8.20. Appl., 22.10.18.

GASEOUS nitrogen compounds from an electric furnace are partially condensed, the residual undensified gases are reheated to a temperature suitable for absorption, and then absorbed by dry bases at an elevated temperature.—W. J. W.

Nitric acid and nitrogen compounds; Process of manufacturing — from atmospheric air. J. F. Sanders, Assr. to F. H. Churchill and O. P. Coshaw. U.S.P. 1,349,919, 17.8.20. Appl., 23.10.17.

A MIXTURE of nitrogen, oxygen, and hydrogen is passed over platinum heated to incandescence by an electric current.—W. J. W.

Ammonia synthesis; Preparation of a mixture of hydrogen and nitrogen for —. G. P. Gerfin and M. Mauran, Assrs. to The Nitrogen Corp. U.S.P. 1,349,756, 17.8.20. Appl., 15.11.18.

A MIXTURE of hydrogen and air is formed in which the hydrogen is in excess of the amount which would combine with the oxygen in the air. The mixture is passed through a conduit in which it is ignited, the temperature being kept sufficiently high to ensure complete elimination of oxygen, after which the reaction products are cooled, dried, compressed, and purified.—W. J. W.

Hydrogen; Material for use in operations with — under pressure and at high temperatures, specially for catalytic preparation of ammonia. Badische Anilin- u. Soda-Fabr. G.P. (A) 298,199, 14.5.13, and (B) 306,333, 18.6.16. Additions to 291,582 (see E.P. 29,260 of 1912 and 13,258 of 1913; J., 1913, 1010).

(A) STEEL alloys containing chromium, vanadium, tungsten, etc., remain suitable for use even if they contain relatively much carbon. Provided the alloying metals are present in sufficient quantity the strength is maintained even when the carbon is converted into gaseous compounds and liberated. A high proportion of nickel should be avoided. (B) If larger quantities of the alloying metals (chromium, tungsten, etc.) are present, steel containing a relatively high proportion of nickel can be used. A suitable alloy contains tungsten 5%, nickel 5%.—W. J. W.

Ammonia; Preparation of dry — from nitrolim by means of superheated steam. E. Wiedemann. G.P. 321,204, 28.5.14. Addn. to 311,959 (J., 1919, 630 A).

For the process described in the original patent, a furnace with superposed hearths or shelves provided with stirring gear is employed, nitrolim being introduced at the top, and superheated steam passed in at the lower end.—W. J. W.

Ammonium nitrate; Manufacture of —. F. A. Freeth and H. E. Cocksedge. E.P. 149,095, 20.5.19.

AMMONIUM sulphate and sodium nitrate are caused to react in suitable proportions, and the sodium sulphate precipitated is removed. Calcium sulphate is added to the solution to separate sodium sulphate as a double salt. After removal of this salt,

ammonium nitrate may be obtained by cooling the solution without further dilution, the mother liquor being used for a fresh cycle of operations. (Cf. E.P. 126,678; J., 1919, 499 A.)—W. J. W.

Hydrocyanic acid and cyanides; Manufacture of —. M. E. Mueller. U.S.P. 1,317,518, 27.7.20. Appl., 25.8.19.

FERROCYANIDES are treated with metallic copper in presence of an acid capable of reacting with the ferrocyanide, the liberated hydrocyanic acid being distilled off.—W. J. W.

Furnace [for fixing nitrogen]. C. P. Hidden. Assr. to Nitrogen Products Co. U.S.P. 1,318,175, 3.8.20. Appl., 27.1.19.

A VERTICAL cylindrical retort is provided with an inner concentric cylinder, and the nitrogen-absorbing material is fed downwards through the annular column thus formed. This column is heated externally by hot gases, and internally by burning fuel gas and air which are injected downwards into the lower end of the inner cylinder by central vertical supply pipes. Nitrogen passes upwards through the annular column of the material. The material delivered at the bottom is cooled externally and internally, and adhesion of the charge to any part of the retort is prevented. The cooling means include a relatively cool jet of nitrogen directed into contact with the lower end of the column.—W. F. F.

Aluminous materials; Conversion of powdered — into granular form. J. J. Hood. E.P. 149,453, 20.5.19.

POWDERED aluminium hydroxide, bauxite, china clay and the like are converted into granular form by moistening with nitric or hydrochloric acid or a solution of their aluminium salts, heating to form a cake, crushing, and decomposing the salt by heating to dull redness. The granular material obtained is suitable for refining mineral oils (E.P. 16,617 of 1908; J., 1909, 1081) or for decomposing carbon bisulphide in coal gas (cf. E.P. 143,641; J., 1920, 510 A).—C. I.

Zirconium oxide (zirconia); Process of separating and extracting — from ores and minerals. J. Gordon. U.S.P. 1,340,888, 25.5.20. Appl., 16.10.18.

MINERALS containing zirconium are fused with a mixture of a chloride and an oxide as a step in the process of producing zirconia.

Titanic oxide; Method of obtaining —. L. E. Barton. Assr. to The Titanium Alloy Manufacturing Co. U.S.P. 1,318,843, 10.8.20. Appl., 27.2.19.

In the preparation of titanic oxide concentrates by the acid treatment of titaniferous materials containing sulphides of iron, the latter are first converted into oxygenated compounds.—C. I.

Magnesium compounds; Purifying —. C. E. Dolbear. U.S.P. 1,348,933, 10.8.20. Appl., 3.9.19.

MAGNESIUM compounds are treated at an elevated temperature with a solution of an ammonium salt, the gas given off is passed into a comparatively cool solution of the magnesium salt formed in a previous operation, and the precipitated magnesium compound separated.—C. I.

Potassium and other alkali metal compounds; Process of obtaining —. E. H. Westling. U.S.P. 1,349,113, 10.8.20. Appl., 14.10.18.

ANHYDROUS compounds of an alkali metal are heated with the sulphate of a heavy metal to a temperature sufficient to decompose the latter.

—C. I.

Potassium salts and borax; Recovery of —. K. J. Jacobi. Assr. to Pacific Coast Borax Co. U.S.P. 1,319,131, 10.8.20. Appl., 25.8.19.

THE alkalinity of brine containing potassium salts and borax is reduced by addition of acid, and the brine concentrated and cooled.—C. I.

Alkaline deposits; Process of recovering constituents of value from natural —. C. Sundstrom. Assr. to The Solvay Process Co. U.S.P. 1,319,415, 10.8.20. Appl., 6.10.18.

SOLUTIONS containing potassium chloride, along with sodium chloride, sodium sulphate, sodium carbonate, and borax are cooled to precipitate the three last, and the cleared brine evaporated at first by solar heat, then by artificial heat, with removal at each stage of the precipitated salts. The final saturated potassium chloride solution is cooled and crystallised.—C. I.

Borax; Process of recovering — from solutions containing sodium borates. C. Sundstrom. Assr. to The Solvay Process Co. U.S.P. 1,319,416, 10.8.20. Appl., 21.9.19.

CARBON dioxide is generated in a solution containing sodium metaborate whereby sodium tetraborate is precipitated.—C. I.

Sodium bicarbonate; Process of obtaining — from alkaline waters. C. Sundstrom. Assr. to The Solvay Process Co. U.S.P. 1,319,117, 10.8.20. Appl., 3.1.20.

BRINE containing sodium carbonate is cooled below 0° C. and the precipitated sodium carbonate separated. The precipitated salts are warmed so as to melt the sodium carbonate, the unmelted portion separated and the clear liquor carbonated to precipitate sodium bicarbonate.—C. I.

Potassium chloride and borax; Method of separately obtaining — from certain waters. Method of separating borax from potassium chloride. N. Wrinkle and W. A. Kuhnert. U.S.P. (A) 1,350,089 and (B) 1,350,090, 17.8.20. Appl., 14.7. and 21.7.19.

THE borax is converted into more soluble compounds by addition of (A) sodium hydroxide or (B) an acid, and the potassium chloride is crystallised.—C. I.

Barium monoxide; Process of oxidising — to dioxide. H. Fleck. Assr. to The Peroxide Specialty Co. U.S.P. 1,319,417, 10.8.20. Appl., 5.11.17. Renewed 29.10.19.

BARIUM monoxide is subjected simultaneously to attrition and to the action of an oxidising gas at the requisite temperature.—C. I.

Aluminium nitride; Process for producing — from materials containing aluminic oxide. Process of producing aluminium from aluminic oxide. V. Gerber. U.S.P. (A) 1,350,149 and (B) 1,350,150, 17.8.20. Appl., 28.1.20.

(A) ALUMINIUM nitride is produced by melting aluminium oxide with a reducing agent in the presence of a nitrogenous gas in an electric furnace. (B) Alumina is melted in an electric furnace and treated with carbon and hydrogen for the production of metallic aluminium.—A. R. P.

Carbon bisulphide; Method of making —. H. H. Dow and C. J. Strosacker. Assrs. to The Dow Chemical Co. U.S.P. 1,350,558, 21.8.20. Appl., 15.7.18.

SULPHUR dioxide is brought into contact with heated coke after mixing it with sufficient oxygen to maintain the coke at the requisite temperature.

—C. I.

Hydrogen sulphide; Removal of — from gases. Badische Anilin and Soda Fabrik. G.P. (A) 302,555 and (B) 303,292, 2.7.16.

(A) THE gases are washed with aqueous solutions or suspensions of oxides of iron first in neutral medium, and then, for complete desulphurisation, in alkaline medium. The greater portion of the sulphur is removed by the first wash liquor, and this can very easily be revived by blowing air or oxygen through it, either simultaneously with the hydrogen sulphide gases or subsequently. (B) The gases are treated with alkaline wash liquors containing oxides of iron partly in solution and partly in suspension, a quantity of oxalic acid or cream of tartar, for example, being added, which is insufficient for the complete dissolution of the iron. The liquors are revived by air or oxygen as in the first patent.—G. F. M.

Lime; Process for burning — in a rotary furnace. E. Natho. G.P. 319,054, 6.7.17.

By means of a pipe with nozzles, water is introduced into the furnace cooler under pressure, and, in evaporating, serves to slake the lime uniformly and rapidly.—W. J. W.

Arsenic; Manufacture of —. C. Göpner. G.P. 320,086, 21.11.17.

ARSENIC acid is sublimed and passed over charcoal or coke heated to not less than 300° C., the sublimation being assisted by means of a gas heated above 185° C. The arsenic acid may be produced by roasting arsenic ores at a maximum temperature of 400°.—W. J. W.

Cryolite; Manufacture of —. J. L. C. Eckelt. G.P. 320,690, 12.7.17.

HYDROGEN fluoride is drawn from the vessel in which it is formed, by means of a water pump actuated by a solution of sodium aluminate. —W. J. W.

Soluble salts; Conversion of — into other salts, especially nitrates of potassium, sodium, and magnesium. H. Hampel. G.P. 321,039, 11.3.19.

THE acid radicle of the initial salt is precipitated in a slightly soluble form, and then converted into a soluble salt in combination with a less soluble one by the action of ammonia and an acid gas or anhydride. These salts in turn are treated with the desired acid for the end product, in its free state, by which means the initial precipitating salt for the process is recovered. The method is applicable to the production of nitrates of potassium, sodium, and magnesium, the sulphates being first treated with calcium nitrate, the precipitated calcium sulphate then converted into calcium carbonate and ammonium sulphate by means of ammonia and carbon dioxide, and the calcium carbonate finally converted into calcium nitrate by treatment with nitric acid.—W. J. W.

Salt solutions, especially solutions of potassium salts; Clarification of —. F. Krupp A.-G. Grusonwerk. G.P. 321,767, 19.10.17.

THE mud in salt solutions is mechanically removed in a continuous fashion and washed in another vessel, where its soluble portions are dissolved by fractional extraction and adherent liquor is separated.—W. J. W.

Radium; Production of compounds of —. H. O. Hedstrom. E.P. 149,552, 20.10.19. Addn. to 136,768 (J., 1920, 156A).

SEE U.S.P. 1,338,831 of 1920; J., 1920, 449A.

Potassium chloride; Manufacture of — from natural silicates, rocks, minerals, residues, or wastes containing potassium. E. A. Ashcroft. U.S.P. 1,350,091, 17.8.20. Appl., 13.11.17.

SEE E.P. 113,211 of 1917; J., 1918, 180A.

Copper sulphate solutions from ores; Process of producing —. J. S. Ross. U.S.P. 1,350,239, 17.8.20. Appl., 14.7.20

SEE E.P. 143,973 of 1919; J., 1920, 544A.

Silicon tetrachloride; Process of making —. R. W. Moore, Assr. to General Electric Co. U.S.P. 1,350,932, 24.8.20. Appl., 18.2.18.

SEE E.P. 141,908 of 1919; J., 1920, 448A.

Ammonia from coal-gas. U.S.P. 1,349,393. See IIA.

Acid-resisting material. G.P. 321,029. See VIII.

Lampblack and hydrogen. G.P. 312,546. See XIII.

VIII.—GLASS ; CERAMICS.

Porosity [of ceramic materials]; Quick determination of —. L. Bertrand and C. Boulanger. La Ceramique, 1920, 23, 77. Keram. Rundsch., 1920, 28, 345—346.

THE material is immersed in carbon tetrachloride instead of in water. Owing to the lower surface tension of the former, a paving tile previously dried at 250° C. is saturated with the liquid in one-quarter to two hrs., compared with 24—48 hrs. required if water is used. For accurate work the body after immersion is weighed in a light metal vessel of zinc or brass in order to prevent losses due to rapid evaporation of the carbon tetrachloride. If p' be the difference between the dry weight of the test-piece and its weight when suspended in the immersion liquid, and p'' be the difference between the weight after immersion and the dry weight, then the porosity is $p''/(p'+p'')$.—H. S. H.

PATENTS.

Glass-drawing bait and method of using it. H. K. Hitchcock, Assr. to Pittsburgh Plate Glass Co. U.S.P. 1,349,200, 10.8.20. Appl., 23.10.17.

THE glass-engaging portion of a cylindrical bait is made of metal with a coefficient of expansion substantially the same as that of glass. When drawing glass cylinders the relatively thin lower edge of the metal bait is immersed in molten glass until the glass is welded to it. The bait is then drawn upwards, and the resulting cylinder severed at a point near the bait.—H. S. H.

Quartz; Production of articles impervious to gases from —. Deutsch-Englische Quarzschmelze G.m.b.H. G.P. 319,895, 5.2.18.

A MASS of fused quartz from an electric furnace is subjected to blowing and pressing under heat, and heat is then applied directly to the surface by which means a high surface-glaze is obtained. During the operation a layer of quartz may be sintered on to the under surface, on which a glaze may also be produced by heating. The process ensures absolute imperviousness of the material to gases.—W. J. W.

Clays; Treatment of — and manufacture of articles and materials therefrom. W. Smith. E.P. 149,440, 13.5.19.

ARTICLES and materials uniting the properties of clays and carbon are made by mixing clay with bituminous or oil shale or other material containing

a volatile compound of carbon which, on heating, is decomposed with deposition of carbon. The mixture, or an article made from it, is embedded in powdered coke or oil shale so as to impose a resistance to the escape of the volatile matter, and is then fired at 700°—800° C., at which temperature the product has a maximum porosity and carbon content. If the product is then fired to 1600° C. it becomes very hard and resistant to acids (resembling carborundum), and may be ground and used as an abrasive material. Alternatively, biscuitware may be saturated with a suitable liquid hydrocarbon and fired with exclusion of air so as to produce a similar product.—A. B. S.

Bauxite; Process of manufacturing dense ware from —. A. F. Meyerhofer, Assr. to Chemical Foundation, Inc. U.S.P. 1,350,825, 24.8.20. Appl., 11.10.16.

DENSE, non-porous refractory bauxite wares are obtained by heating the bauxite, finely grinding the product and mixing it with water to form a plastic mass which is then shaped and baked.

—D. F. T.

Acid-resisting material impervious to water; Preparation of —. J. Frenz. G.P. 321,029, 11.10.17.

PRIME or other absorptive material is finely powdered, dried, mixed with cement or hydraulic lime, strongly heated, and then impregnated with paraffin. A tar product is then added, after which the mass is heated to promote intimate admixture of the ingredients, and cooled.—W. J. W.

Flooring material; Manufacture of a permanently rough stoneware —. M. Gotthard. G.P. 321,158, 28.12.13.

GRAINS of clay, rich in iron, are mixed with stoneware raw material, the action of heat during the firing causing these to swell.—W. J. W.

Tunnel kilns. U.S.P. 1,348,510—1. See I.

Corundum. G.P. 319,814. See X.

IX.—BUILDING MATERIALS.

Concrete. Lea. See X.

Bituminous coatings for concrete. See XIII.

PATENTS.

Walls, linings, panels, roof-coverings, coach bodies or the like; Composition for use in the construction of —. J. F. Leger. E.P. 2311, 29.1.14.

A **STRUCTURAL** composition with a metallic trellis work reinforcement consists of a mixture of magnesia 1 pt., Canadian asbestos fibre $\frac{1}{2}$, common asbestos fibre, powder or waste $\frac{1}{2}$, corkwood $\frac{1}{2}$, wood pulp 1, tale $\frac{1}{2}$, barium sulphate $\frac{1}{2}$ pt., and sufficient magnesium chloride solution of 15°—30° B. (sp. gr. 1.08—1.26) to form a paste which, when set, binds the materials together.—A. B. S.

Fibrous composition [for paving]; Apparatus and process for manufacturing —. G. A. Henderson. E.P. 148,611, 30.4.19.

Wood chips varying in size from impalpable dust to particles which will pass a mesh of 4" x 4" are boiled in order to remove sap, etc., after which, if necessary, they are freed from pyroligneous acid by agitation with a neutralising agent. The chips containing approximately 66% of moisture are then introduced by means of a screw conveyor into a drum with central revolving blades, which is surrounded by a tank of bitumen heated by a furnace; the fumes from the tank are drawn through the drum and carry off the dust to a collecting bin.

The chips with 15—20% of residual moisture are cooled and mixed for 1 min. in steam-jacketed pug mixers with sulphuretted bitumen prepared from sulphur and artificial asphalt produced from petroleum and preheated to 300° F. (149° C.), the proportions being chips 40 and bitumen 60%. The mixture flows into a drum of the type described, where it is heated to 250° F. (121° C.) in 5 mins. The impalpable wood dust, which may be mixed with road dust or other mineral dust, is introduced in small quantities at regular intervals, and the mixture is cooled and compressed into the required shape.—W. J. W.

Tiles, flags, sheetings or the like of cement and fibre; Manufacture of —. E. Steiger. E.P. 149,120, 26.6.19.

EFFLORESCENCE on tiles etc. made of asbestos fibre and Portland cement may be prevented if tiles containing more than 2% of water, but not sufficient to saturate them, are exposed to the action of carbon dioxide. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 1, of Patents and Designs Acts, 1907 and 1919, to E.P. 23,559 of 1912; J., 1913, 912.) —A. B. S.

Concrete hardening. C. Ellis and H. S. Riederer. U.S.P. 1,348,099, 27.7.20. Appl., 23.3.15.

PORTLAND cement concrete is made with a superficial layer in which are distributed copperised iron granules of a fineness between 15- and 25-mesh. —W. J. W.

Slag from refuse. E.P. 119,033. See XIXb.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel; Influence of vanadium on the determination of chromium in high-speed tungsten —. P. Slawik. Chem.-Zeit., 1920, 44, 633.

In the titration of chromium in steel containing vanadium and tungsten, a red-brown coloration develops as soon as an excess of ferrous sulphate solution has been added and the colour changes to yellow during the titration with permanganate, thus obscuring the end-point. The red-brown coloration is due to the formation of a complex vanadium phosphotungstate (phosphoric acid is used with sulphuric acid to dissolve the sample), but its presence does not affect the accuracy of the determination of the chromium if, in titrating the excess of added ferrous sulphate, permanganate solution is added until a red coloration is obtained which changes to yellowish-brown and not to pink. —W. P. S.

Steel; Effect of arsenic in —. P. E. McKinney. Chem. and Met. Eng., 1920, 23, 294.

COMPARISON of steel without addition of arsenic with the same steel after the addition of 0.1 and 0.5%, respectively, showed that up to 0.3% As appears to be without detrimental action so far as the static tests are concerned.—W. H. C.

Carbon-free ferronickel in a high-frequency induction furnace. D. Wilson. Chem. and Met. Eng., 1920, 23, 251.

Discs of electrolytic nickel, contained in a quartz crucible, placed within a quartz tube and surrounded with a coil, were melted and thoroughly agitated and mixed by the electro-magnetic forces induced in the nickel when an electric current was

passed through the coil. Iron was added from time to time, and the mixing was so efficient that the opposite ends of a cast rod of alloy differed by less than 0.01% in composition. 4.4 lb. of metal was charged, melted, and poured within 40 mins. with an expenditure of 12 kw. of electric energy.

—W. H. C.

Lead and silver refining slags and residues; Complete analysis of —. W. Stahl. Chem. Zeit., 1920, 44, 649—650.

THE finely-divided material is dissolved in nitric acid, the insoluble matter filtered off and fused with sulphur-sodium carbonate mixture. The insoluble sulphides in the melt are dissolved in nitric acid and added to the original filtrate, which is treated with hydrogen sulphide. The precipitate is extracted with ammonium sulphide, the extract added to the filtered solution of the fusion melt, and the residue used for the determination of copper, lead, and silver, while iron and zinc are determined in the filtrate from the hydrogen sulphide treatment. The solution of the sulpho-acids is acidified with dilute sulphuric acid, the precipitate is dissolved in colourless ammonium sulphide, the solution treated with potassium chlorate and hydrochloric acid, diluted, tartaric acid added, and the arsenic precipitated with magnesia mixture in the slightly ammoniacal solution. Tin and antimony are separated by hydrogen sulphide in boiling oxalic acid solution, the antimony sulphide being weighed as such after ignition at 300° C. in carbon dioxide, and the tin in the filtrate deposited by electrolysis and weighed as metal. Sulphur is determined in a separate portion by fusion with sodium carbonate-nitrate mixture, and eventual precipitation as barium sulphate, the lead being removed by passing carbon dioxide through the alkaline solution of the melt.—A. R. P.

Copper ores; Leaching and concentrating mixed —. A. Crowfoot and K. H. Donaldson. Eng. and Min. J., 1920, 110, 471—474.

THE material used in the tests consisted of old slime tailings from a dump and contained 1.39% Cu, 0.85% Cu being soluble in acid. The slime mixed with sufficient water to give a 1:1 pulp was passed through a tube mill; sulphuric acid was added to the discharge from the mill, which was then pumped into leaching tanks. After standing for some time the pulp was passed over a drag belt classifier; the sands were returned to the mill and the slimes passed directly to a flotation plant. The concentrates from this went to the smelter, while the tailings were run into a Dorr thickener. The overflow from the latter went to the precipitating tanks, and the slimes were filtered and washed in an Oliver filter, the filtrate going to the precipitating tanks, where the copper was precipitated on iron. The process gave an 84% extraction.—A. R. P.

Copper refinery; The power problem in a —. L. Addicks. Chem. and Met. Eng., 1920, 23, 275—278.

SUFFICIENT steam cannot be obtained from the boilers heated by the waste gases from the smelting furnaces to meet the requirements for generating current, for heating the electrolyte, for evaporating and other needs. The methods of supplying the extra quantity are discussed, and several tables and diagrams are given, together with a summary showing the distribution of the steam requirements.

—W. H. C.

Zinc concentrates; Roasting — in suspension. C. H. Fulton and J. B. Read. Eng. and Min. J., 1920, 110, 405—408.

THE dry, finely-divided ore (e.g., flotation concentrate), preheated to 60°—100° C., is fed by means

of a hopper and screw conveyor into a pipe where it meets a stream of moderately preheated high-pressure air (20—60 lb.), by which it is carried through an injector pipe into a long vertical combustion tube lined with refractory material. An excess of air over that necessary to roast the ore is forced by means of a cycloidal blower through two stoves, heated by natural gas, wherein it is heated to the necessary temperature (800° C.) to start the combustion, after which it enters the vertical tube of the furnace below the injector pipe, thus carrying the ore up the tube and at the same time roasting it. When the ore reaches the top of the tube it falls through a larger annular space, in which the roasting is completed, into the ore bin. In this way the heat of combustion of the ore is fully utilised, and the issuing gases, after passing through a Cottrell plant, are sufficiently rich in sulphur dioxide and oxygen to be utilised directly in the manufacture of sulphuric acid. The average sulphur content of the roasted product from several tests was 3.6%, much of which was present as sulphate. The amount of air required was 41—55 cub. ft. per lb. of blende, and the volume of the issuing gases about 50 cub. ft. per lb., containing 8% SO₂, 10% O₂, and 82% N₂.—A. R. P.

Zinc; Analysis of commercial —. E. Olivier. Ann. Chim. Analyt., 1920, 2, 199—207, 226—234.

METHODS, chiefly colorimetric, are described for the determination of impurities in commercial zinc. The methods of separation used are, briefly, as follows:—The sample is dissolved in nitric acid; a clear solution is obtained unless tin is present. The solution (clear or turbid) is treated with 10 c.c. of ferric chloride solution (0.1 g. Fe), and excess of ammonia is added; the ferric hydroxide precipitate formed also contains the tin, lead, arsenic, and antimony, whilst the solution contains the zinc, copper, and cadmium. When the mixture is filtered and the filtrate treated, drop by drop, with sodium sulphide solution, cadmium and copper sulphides are precipitated before the zinc. Addition of cyanide prevents the formation of copper sulphide. All commercial zincs are completely soluble in a mixture of nitric and tartaric acids, and the solution remains clear when an excess of ammonia is added; the addition of sodium sulphide precipitates first the lead, then the copper and cadmium, and finally a portion of the zinc, whilst arsenic, antimony, tin, and the greater portion of the zinc remain in solution. In the colorimetric determinations, iron is estimated as thiocyanate and the other metals as sulphides, the comparison solutions being prepared from a specimen of zinc containing known amounts of the metals.—W. P. S.

Zinc; Allotropy of —. K. E. Bingham. Inst. Metals, Sept., 1920. [Advance copy.] 21 pages.

FROM observations of the electrical resistance, thermal E.M.F., electrolytic potential, specific gravity, hardness, mechanical properties, thermal curves, and microstructure of the pure metal (99.97% Zn), it is concluded that zinc exists in three allotropic forms, the temperatures at which the critical changes occur being between 160° and 210° C. and between 300° and 340° C.—W. E. F. P.

Casting temperature; Measurement of — in the brass foundry. J. Arnott. Engineering, 1920, 110, 277.

MEASUREMENTS of the temperature of molten brass by radiation and optical pyrometers are rendered unreliable by the oxide films on the surface of the metal and the quantities of fume evolved. When using thermocouples with protecting sheaths the time lag is an undesirable feature; it is, therefore, recommended to use a nickel—nickel-chromium (9% Cr) couple insulated with asbestos and en-

cased for the greater part of its length in a steel tube, a few inches above the junction being left bare for immersion. This couple, which has an E.M.F. of 40 milliv. at 1000° C., will indicate the temperature of the molten metal within 1 min. of immersion and, when the junction is burnt through the ends, may be readily welded together by means of the oxy-acetylene flame. Examples are given of the effect of casting temperature on the tensile strength of gun-metal.—A. R. P.

Ferrocium. A. Hirsch. Trans. Amer. Electrochem. Soc., 1920, 711—714. [Advance copy.]

THE preparation and properties of ferrocium are described, and the use of "Misch-metal" (an alloy of metals of the cerium group) as a deoxidiser discussed. Addition of the latter to cast iron renders the castings softer, denser, more easily machinable and free from gas and pinholes and increases the transverse strength. When added to molten copper just before pouring, the resulting metal is free from oxides and gases, and the tensile strength, elongation, and reduction of area are raised.—A. R. P.

Copper-zinc alloys prepared by melting or by electro-chemical processes; Chemical and electro-chemical properties of —. F. Sauerwald. Z. anorg. Chem., 1920, 111, 243—279.

THE properties of copper-zinc alloys obtained by melting are to a large extent independent of the composition; this is due to the protecting action of the copper in the mixed crystals. At 380° C. the protecting action of the copper is no longer operative, owing to the increased mobility of the atoms, and the properties are then dependent on the concentration. In alloys electrolytically deposited at the ordinary temperature the copper has not this protecting action, but if the alloy is formed by electrolysis of fused salts at 300° C. the product is much the same as that formed by melting. (Cf. J.C.S., Oct.)—J. F. S.

Copper-aluminium-zinc alloy; Corrosion of a screw fitting made of —. O. Bauer. Z. Metallkunde, 1920, 12, 129—131. Chem. Zentr., 1920, 91, IV., 256.

A SCREW fitting made of a zinc alloy containing 4.85% Cu, 2.19% Al, 0.92% Pb, 0.15% Sn, and 0.03% Fe became brittle and partially disintegrated after a short time in use. Alloys containing much zinc should never be used on boilers, especially in places where they are likely to become damp in contact with more electropositive metals or iron, bronze, or brass.—G. F. M.

Materials [metals and alloys and concrete]; Effect of temperature on some of the properties of —. F. C. Lea. Sect. G., Brit. Ass., 1920. Engineering, 1920, 110, 293—298.

TENSILE tests from 0° to 900° C. and hardness tests from 0° to 500° C. were carried out in electrically-heated furnaces on metals and alloys. Both tensile strength and hardness were found to decrease as the temperature was raised. In the case of steel used for reinforcing concrete a breaking strength of 7 tons per sq. in. was reached between 615° and 640° C., so that concrete beams cannot be expected to stand if exposed to a fire for sufficiently long to allow the steel to reach approximately 650° C. Further tests were carried out on concrete cylinders and cement briquettes and cubes to ascertain the protective influence of concrete on the steel reinforcement. The results indicated that the usual thickness of concrete was insufficient to prevent the steel from being heated to the dangerous temperature of 650° C. if exposed for several hours to a fierce fire.—W. H. C.

Metals; Metastability of the — as a consequence of allotropy and its significance for chemistry, physics, and technics. H. E. Cohen and H. B. Bruins. Z. physik. Chem., 1920, 94, 443—449.

A REPETITION and confirmation of previously published work (see J., 1914, 597, 1159; 1915, 908) in connection with a change in density of metals after various treatments.—J. F. S.

PATENTS.

Iron; Process of extracting — from its ores. C. C. Jones. U.S.P. 1,348,804, 3.8.20. Appl., 19.6.16.

A MIXTURE of iron ore and petroleum is embedded in solid carbonaceous fuel in containers from which air is excluded, and the containers are then heated to a temperature below fusion point, but sufficiently high to reduce the ore. The reduced iron retains enough carbon from the petroleum in its interstices to form a conglomerate mass.—W. J. W.

Spiegeleisen or high-percentage ferromanganese; Reducing pyrolusite [to manganous oxide] before use in the production of —. J. Hub. G.P. 322,610, 25.12.12.

A COMPACT mixture of pyrolusite and coal or small coke is gradually fed into a furnace and heated to red-heat; the reaction between the coal and the oxygen liberated raises the mass to white-heat, the charge melts, and reduction is completed, a slag of manganous oxide being formed.—L. A. C.

Rusting of iron; Prevention of the —. H. Koelsch. G.P. 319,855, 25.3.14.

THE surface of the iron is treated with a nitrite—for example, a solution of sodium nitrite in glycerin or a mixture of sodium nitrite and vaseline.

—G. F. M.

Metallic oxide ores; Reduction of —. J. W. Moffat. U.S.P. 1,348,889, 10.8.20. Appl., 15.8.19.

A FURNACE for reduction of oxide ores consists of a stationary, horizontal, cylindrical reduction chamber with an air-tight charging gate at the top and an air-tight discharge outlet at the bottom, and is fitted with apparatus working in closed orbits for lifting and re-lifting the charge from the bottom of the furnace and dropping it again from the upper part of the furnace.—J. W. D.

Ores, metal oxides and the like; Reduction of —. Kohle und Erz, G.m.b.H. G.P. 320,065, 30.11.15.

REDUCING gases are heated above the theoretical reduction temperature, by electrical means or otherwise, before being passed through the charge of ore and coal.—C. A. M.

Manganese ores; Treating oxide —. G. H. Clevenger and M. H. Caron, Assrs. to Research Corp. U.S.P. 1,349,322, 10.8.20. Appl., 23.9.18.

THE ores are treated to reduce the manganese to a stage lower than the manganic oxide stage and the manganese is then concentrated by magnetic separation.—J. W. D.

Lead; Removing — from copper scrap. J. L. Jones, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,319,382, 10.8.20. Appl., 16.1.19.

COPPER scale is added to molten copper scrap to oxidise the impurities, and the purified copper is separated from the oxidised impurities.—J. W. D.

Heat regenerator [for metallurgical furnaces]; Process of protecting metal pipes exposed to high temperatures. L. B. Skinner. U.S.P. (A) 1,350,267 and (B) 1,350,269, 17.8.20. Appl., (A) 10.2.19, (B) 11.2.18; (B) renewed 9.7.20.

(A) THE passages for conducting the gases to and

from the furnace are separated by a metallic wall, and the interiors of the passages are coated with an adherent protective coating of condensed metallic fume. (b) The interior surfaces of the conduits of heat regenerators are coated with the compounds of volatile metals present in the fume (e.g., zinc oxide) by passing the gases through the pipes at such a temperature as to deposit a coating of the fume on them without burning the iron. The furnace is then operated in such a manner that the coated pipes are at a temperature above 1000° C. while the air for combustion is passing through them.—A. R. P.

[Nickel] alloy. H. S. Cooper, Assr. to Zircon Tool and Alloy Co. U.S.P. 1,350,359, 24.8.20. Appl., 22.8.18.

AN alloy of nickel with 0.5–2% Zr and at least twice as much aluminium and silicon as zirconium is suitable for making high-speed cutting tools.

—A. R. P.

Copper and zinc; Recovery of — from burnt pyrites. Reisenegger. G.P. 307,085, 7.3.17.

CHLORINE is led into a sludge of burnt pyrites and water; copper and zinc are dissolved as chlorides and are separated by crystallisation.—L. A. C.

Pyrites; Process for extracting zinc from burnt —. Process for separating zinc from burnt pyrites by extraction with dilute acid. Farbenfabr. vorm. F. Bayer und Co. G.P. (a) 312,384 and (b) 320,066, 11.5.18.

(A) BURNED pyrites is leached with hydrochloric acid or sulphuric acid and sodium chloride, while chlorine is simultaneously introduced. (b) By first mixing the burnt pyrites with manganese are the zinc content is reduced below 1%, and the extracted material may then be smelted to obtain the iron.—C. A. M.

Noble metals; Process and apparatus for obtaining — from very dilute solutions (sea-water etc.). E. Zander. G.P. 310,722, 21.3.17.

A MEASURED larger quantity of another substance (e.g., a mercury salt) is added to a very dilute solution of a noble metal, and precipitated simultaneously with the latter, e.g., by means of bases, or hydrogen sulphide, in a form which can be rapidly separated by filtration or otherwise.—C. A. M.

Light metals; Process for recovering — from turnings, residues, and ashes. K. Hess. G.P. 320,220, 30.7.18. Addn. to 318,304 (J., 1920, 520 A).

RESIDUES etc. containing light metals are fused with rock salt and the mass of salt saturated with impurities cooled and left in cold water until the salt has dissolved. The salt may subsequently be recovered from the solution.—C. A. M.

Zinc ore; Preparation of briquettes of — suitable for smelting. Schlesische A.-G. für Bergbau und Zinkhüttenbetrieb. G.P. 319,813, 28.3.14.

PLASTER of Paris is used as a binding agent for zinc ore briquettes, with or without the addition of pitch or "cell-pitch".—C. A. M.

Zinc and corundum; Alumino-thermic process of obtaining —. Kohle und Erz G.m.b.H. G.P. 319,814, 8.5.17.

AN intimate mixture of aluminium with zinc oxide (as pure as possible) and the same quantity of zinc dust is subjected to the thermite process. The speed of the reaction can be regulated, and corundum is obtained as a by-product.—C. A. M.

Zinc distillation process; Utilisation of the residual ash from the — by blowing with air or gas. Schlesische A.-G. für Bergbau und Zinkhüttenbetrieb. G.P. 321,526, 7.11.13.

AFTER each distillation the ash is collected in pockets situated below the muffles, and by means of a current of air or other gas, the heat contained in the ash is utilised for preheating the next charge in the muffles.—J. H. L.

Aluminium; Treatment of — with cadmium. S. Buchalo. G.P. 320,139, 26.1.15.

FROM 0.5 to 5% of cadmium is added to fused aluminium at a temperature not materially exceeding the m.p. of the bath, and the mixture vigorously stirred and rapidly heated to over 770° C., before being poured into moulds. The cadmium volatilises at 770° C., and combines with the oxygen in the air-bubbles in the molten metal, so that the particles of aluminium oxide in the latter become coated with cadmium oxide, which separates readily from molten aluminium. The resulting casting is finely granular, homogeneous, free from bubbles, and has increased strength and elasticity.

—C. A. M.

Blast-furnaces; Process for treating ores in —. L. P. Basset. U.S.P. 1,349,598, 17.8.20. Appl., 12.10.17.

XI.—ELECTRO-CHEMISTRY.

International Weston cell; Metastability of the — and its unsuitability as a standard of [electrical] tension. E. Cohen and A. L. T. Moesveld. Z. physik. Chem., 1920, 95, 285–304.

THE cell recommended by the International Conference on Electrical Standards and Units, containing a 12.5% cadmium amalgam, and the cells supplied by the Weston Co., containing 12–13% cadmium amalgam, are both metastable below 12° C., and suddenly become stable with a change of E.M.F. of 6 millivolts. They are therefore unsuitable as standards of electromotive force. A cell,

built on the same lines, but containing 8% cadmium amalgam is recommended; this is stable from 0° to 40° C., and follows the temperature formula put forward by the International Conference. (*Cf.* J.C.S., Oct.)—J. F. S.

XII.—FATS; OILS; WAXES.

Oxidised fatty acids in olive oils extracted with carbon bisulphide; Determination of —. H. Stadlinger. Z. öffentl. Chem., 1920, 26, 162—161, 169—172.

RESIN-LIKE substances giving the Liebermann-Storch reaction, and apparently related to oxidised fatty acids, were isolated by Twitchell's method from technical olive oils which had been extracted with carbon bisulphide. The following results were obtained with 47 commercial samples of such oils:—Unsaponifiable matter, 0.2—9.6; oxidised fatty acids, 1.3—12.8; and normal fatty acids, 77.2—91.7%. The results obtained in the determination of oxidised fatty acids will vary with the nature of the petroleum spirit used for their separation. Thus, the amounts determined in 7 samples by means of commercial petroleum spirit fractionated at about 70° C. ranged from 1.3 to 6.5%, whilst with "normal benzene" they were 7.1—14.0%. The petroleum spirit used should preferably have sp. gr. 0.695—0.705 at 15° C., b.p. 65°—95° C., and should be as free as possible from unsaturated and benzene hydrocarbons.—C. A. M.

Cottonseed oil products; The Kreis [rancidity] reaction of —. W. B. Smith. J. Ind. Eng. Chem., 1920, 12, 764—766.

REFINED cottonseed oils and their products sometimes contain chromogenic substances, derived from the crude oil, which may cause a non-rancid oil to give a positive reaction with the Kreis test (*cf.* Kerr, J., 1918, 475 A); the latter is, therefore, not entirely trustworthy for the detection of rancidity in cottonseed oil.—W. P. S.

Oils and fats resistant to changes of temperature, and melting and solidification points of fats. A. Eisenstein. Oel u. Fettind., 1919, 1, 499—501, 527—528, 548—549, 573—575. Chem. Zentr., 1920, 94, II., 811—812.

MIXTURES of triglycerides probably behave like mixtures of fatty acids in showing a m.p. lower than

the calculated value. The melting point curve of mixtures of palmitic acid and stearic acid has portions which are nearly straight lines between 70 and 100% of palmitic acid and 60 and 100% of stearic acid. The m.p. curve of mixtures of Borneo tallow and coconut oil lies partly below and partly above the calculated curve. The more mixed glycerides contained in an oil the greater its resistance to cold, and the smaller the proportion of high-melting fat resistant to heat which can be obtained at a given temperature.—C. A. M.

Catalytic actions at solid surfaces. I. Rate of change conditioned by a nickel catalyst and its bearing on the law of mass action. E. F. Armstrong and T. P. Hilditch. Proc. Roy. Soc., 1920, A, 98, 27—40. (*Cf.* J., 1920, 116 A.)

THE hydrogenation of linseed oil yields a curve, the initial portion of which (30% of the whole curve) corresponds to the hydrogenation of the whole of the linolenin and most of the linolein; a very abrupt curvature then sets in and this is followed by an approximately linear curve at a much lower slope. Experiments carried out with oil loads of 200, 300, and 400 g. and 0.45 and 1.5 g. of nickel show that the factor v/t (J., 1920, 120 T) depends on the mass of nickel present; the impurities in the oil gradually affect the catalyst, and with the small quantity of nickel the rates are practically the same for loads of 200 and 300 g., but with 100 g. the linear portion of the curve is shortened owing to increased effect of the impurity.—J. F. S.

Fat from starch. Taylor and Nelson. *See* XVII.

PATENTS.

Cotton-seed meats; Treatment of —. C. O. Phillips. U.S.P. 1,347,870, 27.7.20. Appl., 3.8.18.

THE material is incorporated intimately with dilute caustic soda solution, in quantity insufficient to neutralise more than a small fraction of the total fatty acids present, the mixture is subjected to a cooking operation, and the oil then expressed.

A. de W.

Fat; Process for obtaining — from sulphite-cellulose liquors by biological methods. W. Jeroch, and Kriegsausschuss f. pflanzliche u. tierische Oele u. Fette, G.m.b.H. G.P. 305,091, 25.1.17.

AERATED and neutralised sulphite-cellulose liquors to which a nitrogenous substance, such as beet juice, has been added, are inoculated with a culture of *Endomyces vernalis*.—G. F. M.

Silicate soaps; Production of —. T. E. Blasweiler. G.P. 320,829, 11.4.19.

WATER-GLASS is used in such excess that no separation of silicic acid occurs; *e.g.*, 5 kg. of resin is kneaded with 120 kg. of water-glass of 38° B. (sp. gr. 1.35), or 5 kg. of fatty acids from soya bean oil with 150 kg. of water-glass.—J. H. L.

Emulsions; Method of making —. J. A. de Cew. U.S.P. 1,347,734, 27.7.20. Appl., 30.12.18.

As emulsifiable substance is forced into contact with an aqueous solution, the mixture vigorously agitated at about 180° F. (82° C.), under pressure, and the resulting emulsion or emulsoid discharged into an aqueous solution having a lower temperature.—C. A. M.

Soapy liquors; Treatment of —. C. L. Peck. Assr. to The Dorr Co. U.S.P. 1,319,530, 10.8.20. Appl., 1.7.19.

SOAPY liquors are coagulated, and the coagulated particles removed from the liquid by flotation, *i.e.*, the liquid is subjected to the action of gas bubbles and the entrapped coagulated matter floated off. The organic substances in the coagulum are subsequently recovered.—A. de W.

Roller mills [; Controlling the feed of oil seed or the like to —]. J. D. Lee, B. P. Flockton, and Manlove, Alliott and Co., Ltd. E.P. 149,048, 2.5.19.

Solvent for fats. G.P. 320,807. See XIII.

Moulds rich in fat. G.P. 320,560. See XVIII.

Calamus root. G.P. 307,623. See XX.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Satin-white; Preparation and chemistry of —. A. Cobenzl. Chem.-Zeit., 1920, 44, 661–662.

SATIN-WHITE is prepared as follows:—85 kg. of quicklime is slaked with 200 l. of boiling water, the sludge diluted to 450–500 l., and passed through a sieve into a large vat. After cooling, a cold solution of 125 kg. of aluminium sulphate (18% Al_2O_3) in 500 l. of water is slowly added with vigorous agitation, followed by 1100–1200 l. of water to prevent the mass setting. The liquid is finally diluted to 6000 l.; 100 c.c. of the clear solution should not require more than about 25 c.c. of N/10 oxalic acid to render it neutral to phenolphthalein. If more alkaline than this, 4 kg. of sulphuric acid of 40° B. (sp gr. 1.38) is added. Any slight trace of yellow colour is removed by the addition of 100–150 c.c. of a solution of 250 g. of commercial Indanthrene Blue 2GSZ paste in 5 l. of water. The satin-white is then collected in a filter-press. The materials used must be as free as possible from iron, sand, and carbonaceous matter, and the best results are obtained by using slightly basic aluminium sulphate (i.e., that containing only 80–85% of the theoretical sulphuric acid). This may be prepared by treating a solution of the commercial salt with the necessary quantity of lime, allowing the precipitate to settle, and siphoning off the clear liquid for use. Experiments show that the reaction involved in the process is represented by the equation:

—A. R. P.

Bituminous acid-proof coatings for acid-proofing concrete surfaces. Report by Bituminous Materials and Cement Section, U.S. Bureau of Standards. Chem. and Met. Eng., 1920, 23, 287–289.

EITHER bituminous paint, enamel or mastic is used, depending upon the character of the surface to be coated, the strength of the acid, and the desired resistance to changes of temperature and abrasion. The surface to be coated must be clean, dry, and free from dust, and a priming coat should always be applied. Paints are made from bitumen or coal-tar pitch thinned with solvents, the priming material being thinner than the paint. Enamels are mixtures of bitumen of high-melting point thoroughly incorporated with 15–40% of finely-powdered silicious filler; they contain so much bitumen that they melt below 350° F. (177° C.), and are applied hot. The priming material consists of the same kind of bitumen thinned. Mastics are mixtures of hard asphalt, ground with asbestos and finely-powdered silicious mineral filler; when ready for application the mixture contains about 15% of asphaltic binder, 20% of mineral filler, and 65% of properly graded, coarse sand or other aggregate. Mastics are applied hot when the priming coat of thinned asphalt has dried to a tacky condition. Several layers of about 1–32 in., each poured on and spread out with a trowel, are applied one over the other so as to give a final thickness of at least 1 in. General specifications for each kind of material are given,

together with the necessary tests to be applied to ensure compliance with the specifications.

—W. H. C.

“Tunga” varnish resin; Properties and application of —. H. A. Gardner and P. C. Holdt. Paint Manufacturers' Assoc. U.S.A., Circ. No. 102. Aug., 1920. 3 pp.

TUNGA varnish resin (Paint Manuf. Assoc. U.S.A., Circ. 101) is prepared by esterification of rosin with glycerin either as a separate process or during the actual varnish-making process. The resin has a dark reddish-brown colour, sp. gr. 1.132, m.p. (capillary tube) 105°–125° C., acid value (in alcohol-benzol) 16.2, saponif. value 71.59. It is slightly softened by hot alcohol, completely soluble in hot benzol and hot oil of turpentine, insoluble in amyl alcohol, acetone, and petroleum spirit. Tunga resin is suitable for the manufacture of elastic, hard and spar (boat) varnishes. An elastic varnish made from tunga resin and tung oil dried hard in 7 hrs., and the dried film was very resistant to the action of boiling water. Varnishes made from tunga resin with perilla, mixtures of perilla and tung, and perilla and linseed oils have been prepared. With perilla oil there is somewhat more difficulty of manipulation than with tung or linseed oils.

—A. de W.

PATENTS.

Composition impervious to oils, spirits, water, and the like [for coating concrete etc.]. C. H. Iverson and G. S. Roberts. E.P. 149,365, 19.11.18.

A COMPOSITION contains 30–65 pts. by weight of zinc chloride, 30–55 pts. of zinc oxide, and 2–20 pts. of ammonium chloride together with other ingredients such as silica, borax, or powdered glass; magnesium oxide and chloride may replace a portion of the zinc compounds, and agglutinants, such as dextrin, starch, gum, or glue, may also be added. The mixture is made into a paste with water for application to the material to be treated.

—L. A. C.

White lead; Process for producing —. E. Euston. U.S.P. 1,349,334, 10.8.20. Appl., 22.3.19.

APPROXIMATELY neutral lead acetate solution is treated with carbon dioxide gas, basic lead acetate solution is introduced in amount and at such a rate as to maintain a neutral condition of the solution, and the treatment with carbon dioxide gas is continued until a part of the precipitate of basic lead carbonate is converted into the normal salt, and a mixture is obtained to yield a product containing 11.3–14.3% CO_2 .—A. de W.

Insulating and protective coating; Process for the making of an —. E. R. Stowell, Assr. to Stowell Fireproofing Co. U.S.P. 1,350,343, 24.8.20. Appl., 1.7.18. Renewed 10.4.20.

POWDERED silicon carbide (8lb.) is mixed with aqueous sodium hydroxide (1 gall.), and the mixture is allowed to stand in a covered container until the hydrogen gas formed by the action of the alkali on the free silicon is exhausted. The foam-like product is stirred until it is reduced to its original volume, and 1 pint of “50° to 54° sodium silicate” is then added per gall. of composition.—L. A. C.

Lampblack and hydrogen; Preparation of — by decomposition of hydrocarbons. Berlin-Anhaltische Maschinenbau A.-G. G.P. 312,546, 2.6.17.

DECOMPOSITION takes place in a series of retorts, pipes, or chambers heated to successively higher temperatures. For methane the stages are 700°–800°, 900°–1000°, and 1200°–1400° C. In the first stage carbon is deposited as lampblack, and in the last as graphitic carbon.—C. I.

Paint; Preparation of a — from tar and slaked lime. W. Klement. G.P. 318,699, 25.8.17.

A PAINT which furnishes a bright, smooth surface is obtained by mixing tar with milk of lime.

—G. F. M.

Paint for ships' bottoms etc. H. Burstin. G.P. 319,199, 22.11.18.

NEUTRAL or acid naphthenic acid salts of mercury, copper, arsenic, nickel, lead, or other heavy metals, or mixtures of these salts with already known paint materials are employed, either with or without solvents.—G. F. M.

Paint for wood; Preparation of a substance suitable for producing a durable —. K. S. Fuchs. G.P. 320,011, 11.5.19.

THE liquors from the alkaline disintegration of vegetable matter, particularly straw, are cooled, precipitated with acids, and the precipitate filtered off and dissolved in aqueous ammonia. The solution is painted on wood, and the colour is rendered insoluble by heating to 50°–60° C., or by treatment with formaldehyde or ferric chloride.

—G. F. M.

Oil colours and varnishes; Solvent for removing dried —. Tetralin G.m.b.H. G.P. 320,152, 28.5.18.

HYDRONAPHTHALENES, either alone or mixed with other solvents, such as amyl alcohol, are used as solvents for removing dried oil colours and varnishes.—G. F. M.

Solvent for the extraction of resins, fats, essential oils, liquid and solid hydrocarbons, caoutchouc, sulphur, dyestuffs, and the like. Tetralin G.m.b.H. G.P. 320,807, 7.3.16.

THE substances named are dissolved at elevated temperatures, and, if necessary, with the aid of a vacuum, by tetrahydro-, and other more highly-hydrogenised naphthalenes.—G. F. M.

Varnish; Preparation of quickly drying — from tar products. Deutsch-Luxemburgische Bergwerks- und Hütten A.-G., and S. Hilpert. G.P. 320,808, 9.12.16. Addn. to 319,010 (J., 1920, 577A).

THE varnish consists of a mixture of coumarone resin with the resinous organic material obtained from the waste acids which have been used for washing the coal tar fractions boiling above 150° C. For example, the dark brown resin obtained from the waste sulphuric acid which has been used for washing naphthalene is suitable for the purpose.

Pencil leads and the like; Manufacturing —. E. C. R. Marks. From American Lead Pencil Co. E.P. 149,072–3, 7.5.19.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

[*Rubber.*] *Investigations on different coagulants.* O. de Vries. Comm. Central Rubber Stat., Buitenzorg, 1920, No. 19, 163–219.

SULPHURIC acid used in small proportions as a coagulant yields a rubber comparable with the product obtained with acetic acid; with a somewhat larger proportion of sulphuric acid a rubber is obtained with an abnormally slow rate of vulcanisation, but this gradually attains a normal value. Alum is best used with undiluted latex in the proportion of 3–12 g. per l.; the product shows a marked decrease in rate of vulcanisation and in viscosity, the effect increasing with the proportion of coagulant. Formic acid gave irregular results probably owing to the variable composition of the commercial article. Hydrochloric acid in

relatively high proportion gave a rubber with a slow rate of vulcanisation, and the product in two years became tacky and no longer capable of vulcanisation. In coagulating with alcohol, approximately 500 c.c. is needed for 1 l. of undiluted latex, coagulation being instantaneous; the product has a normal rate of vulcanisation, and the process possesses some advantages for experimental purposes. (See also Eaton and Whithy, J., 1918, 99A; Eaton, J., 1918, 99A, 630A.)—D. F. T.

Latex and rubber from individual trees. O. de Vries. Comm. Central Rubber Stat., Buitenzorg, 1920, No. 20, 249–271.

THE yield of individual trees varied from 4 to 71 g. of rubber per day, the rubber content of the latex ranging from 17% to 50%; the necessary vulcanisation period varied from 90 to 160 mins., and the viscosity number from 14 to 90.—D. F. T.

Hevea latex; Natural coagulation of — in the absence of air after addition of lime salts. W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1920, No. 21, 273–291.

THE latex obtained from trees during July and August, when they were leafless, was unusually resistant to spontaneous coagulation in closed vessels, the process being far from complete after 20 hrs., although this period was sufficient earlier and subsequently. During the months in question satisfactory spontaneous coagulation could be ensured by the additional presence of 0.3% of sugar and heating for 7–8 hrs. at 40° C. or of 0.1% of calcium chloride. The rubber obtained with the addition of calcium chloride vulcanised more rapidly than that prepared by the acetic acid process, and was rather less uniform in this respect, but no harmful influence of the calcium salt could be detected.—D. F. T.

[*Rubber.*] *Further data on spontaneous coagulation.* O. de Vries and W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1920, No. 21, 292–311.

RUBBER obtained by spontaneous coagulation of undiluted latex showed practically the same tensile strength and slope as rubber prepared from the same latex by the addition of acetic acid. With latex of high rubber content yielded by trees after a period of rest, spontaneous coagulation proceeded very satisfactorily, but with the latex obtained after heavy tapping, spontaneous coagulation was much less easy and less complete. The crêpe from rubber obtained by spontaneous coagulation was not so pale in colour as the crêpe ordinarily produced.—D. F. T.

Rubber; Determination of sulphur in vulcanised —. P. Dekker. Gummi-Zeit., 1920, 34, 1020–1022, 1044–1045.

FOR the oxidation of free sulphur in the acetone extract from vulcanised rubber, treatment with concentrated nitric acid (sp. gr. 1.4) and a little potassium chlorate is satisfactory. Oxidation with concentrated nitric acid saturated with bromine, followed by evaporation and fusion with a mixture of sodium carbonate and potassium nitrate (Waters and Tuttle, J., 1911, 1268; Tuttle and Isaacs, J., 1915, 436), is satisfactory for the determination of the combined and total sulphur in vulcanised rubber; Rothe's method of oxidation with nitric acid (sp. gr. 1.48) and magnesium nitrate, followed by evaporation and heating, also yields satisfactory results. In order to avoid the strong heating necessary with the last two methods, and thereby to effect a saving in crucibles or flasks, the following modified process is recommended. The sample (1 g.) is gently warmed with concentrated nitric acid (40 c.c.) and anhydrous magnesium nitrate (6 g.) until the liquid begins to froth; the mixture

is then boiled gently for 1 hr., treated with one or two drops of bromine and boiled for a further $\frac{1}{2}$ hr.; the liquid is then evaporated almost to dryness in a porcelain dish, and after the addition of concentrated hydrochloric acid again evaporated until the residue crystallises on cooling; the residue is dissolved in water and its content of sulphate estimated in the usual manner. With this and the other methods mentioned above there is a tendency to somewhat low results if the rubber contains much sulphur.—D. F. T.

PATENTS.

Rubber and similar materials; Process for vulcanising — W. A. Gibbons, Assr. to American Rubber Co. U.S.P. 1,350,798, 24.8.20. Appl., 11.12.16.

VULCANISATION is effected in a medium consisting of an inert gas inside a chamber communicating with the atmosphere; the entry of air into the chamber is prevented by a continuous current of the inert medium.—D. F. T.

Rubber; Process for vulcanising — E. E. A. G. Meyer, Assr. to Morgan and Wright. U.S.P. 1,350,824, 24.8.20. Appl., 29.4.16.

A SMALL quantity of a concentrated solution of caustic alkali is introduced into the mixture to be vulcanised.—D. F. T.

Solvent for caoutchouc. G.P. 320,807. See XIII.

XV.—LEATHER; BONE; HORN; GLUE.

Tannin analysis; Boldracco and Camilla's modification of the official shacco method of — E. Schell. J. Soc. Leather Trades' Chem., 1920, 4, 220—221. (See J., 1920, 123 A, 523 A.)

THE gelatin-acetic acid reagent proposed by Baldracco and Camilla is designed to prove complete detannisation. The modified method effects complete detannisation by the use of more hide powder, which must absorb a corresponding excess of non-tannins. The proposed modification is less accurate, and the nature of the new hide powder and the proportion of hide powder required for a certain strength of tannin are not sufficiently defined. The tannin absorbed is also in a less pure form than by the official method.—D. W.

Chrome tanning. D. Burton. J. Soc. Leather Trades' Chem., 1920, 4, 205—218.

EXPERIMENTS with violet and green chrome liquors on pieces of limed hide have shown that the violet chrome solutions tan more rapidly than green solutions of the same basicity figure, and chromium and neutral salt content. This is explained by the more acid character of the green solutions. The properties of chrome leather are influenced not only by the percentage of chromium, but also by the degree of neutralisation of the chromium salt on the fibre. The completion of the tannage is best judged from the absence of horniness and curling at the edges of a piece of leather after boiling. The leather must be neutralised before boiling, and though it may shrink after boiling, such shrinkage is no criterion for judging the tannage. The tanning properties of a chrome liquor are determined by the chromium content and the hydron concentration. The basicity figure is no guide to the latter.—D. W.

PATENTS.

Condensation products [tanning substances]; Manufacture of — from N- and O-arylsulpho derivatives of aromatic amino- and hydroxy-sulphonic acids. Ges. f. Chem. Ind. in Basel. G.P. 320,613, 20.5.16. Addn. to 319,713 (J., 1920, 553 A).

SOLUBLE aromatic compounds which have two or

more N-arylsulphamino or O-arylsulpho groups, together with a sulpho group in the molecule, are treated with formaldehyde. The products are more soluble and have more effective tanning properties than the initial materials.—W. J. W.

Hides; Process for tanning — P. Ringbauer. G.P. 321,343, 31.10.19.

THE hides are stretched in a frame in the closed tanning-vessel, which is then exhausted. The dilute tanning liquor is then introduced, without destroying the vacuum, and by agitation is caused to exert a steady pressure on both the hair and flesh sides of the hides.—W. J. W.

Extracting tannin. G.P. 320,688. See XVII.

XVI.—SOILS; FERTILISERS.

Soil; Studies of a Scottish drift — W. G. Ogg and J. Hendrick. J. Agric. Sci., 1920, 10, 333—357.

THE glacial drift soil under examination, which is free from calcium carbonate, was separated into fractions by rubbing up and shaking with water, followed by sedimentation, the usual preliminary treatment with acid and ammonia being omitted. The absorptive power of unit weight for ammonia from a solution of ammonium sulphate was greatest in the case of the "clay" fraction, this being closely approached by the "fine silt" and "silt." Powdered granite was divided into mechanical fractions by the same method, and it was found that these fractions had very similar absorptive powers for ammonia from solutions of ammonium sulphate to those of the soil fractions. After ignition there was a reduction in the absorptive power, but this was more marked in the case of the soil fractions than with the granite fractions. The absorbed ammonia was only gradually washed out by percolating water, and the whole of it could not be removed in this way.—W. G.

Soils; Effect of various soluble salts and lime on evaporation, capillary rise and distribution of water in some agricultural — M. I. Wolkoff. Soil Sci., 1920, 9, 409—436.

IN general the soluble salts used, ammonium, potassium and magnesium sulphates, sodium chloride, calcium nitrate, and potassium phosphate, and also calcium oxide, materially decreased the evaporation of soil moisture, there being apparently a direct relationship between the efficiency of the salts in this respect and the osmotic concentration of the soil solution in the top inch of soil. Sodium chloride and calcium nitrate were most effective and potassium sulphate and phosphate least effective in checking evaporation. Calcium oxide was least effective in sea sand and sandy loam, and most effective in clay loam. Sodium chloride decreased the capillary rise in two of the soils examined, whilst calcium oxide in drab clay and potassium phosphate in silt loam tended to increase the capillary rise. In a silt loam treated with sodium chloride, potassium phosphate, or calcium oxide there was a pronounced tendency for an increase in the water content of the top 8 in. of soil, and soil treated with potassium phosphate or calcium oxide contained more water even in the top inch than the untreated soil, although evaporation was decreased from the treated soil.—W. G.

Soils; Effect of gypsum on bacterial activities in — T. M. Singh. Soil Sci., 1920, 9, 437—468.

BOTH ammonification and nitrification were decreased by applications of gypsum to the soil, whereas nitrogen-fixation was stimulated. The amounts of nitrogen fixed by *B. radicola* were much greater in soil than in solution cultures.

Gypsum increased the process, the greatest increase occurring with the largest application of gypsum. An application of 1000 lb. of gypsum per acre increased the yield of red clover, smaller dressings having, however, no effect on either wheat or leguminous crops. The nitrogen and potassium content of the leguminous crops were not affected by gypsum except in the case of red clover, where there was a very large increase in the potassium content. The applications of gypsum increased the acidity of the soil. The addition of lime as well as gypsum to the soil resulted, in some respects, in a better effect than with lime alone, whilst in others a poorer result was obtained. Thus nitrification was better but not ammonification.—W. G.

Soil; Causes of the injurious effect of potassium and sodium salts on the structure of the —. G. Hager. *J. Landw.*, 1920, 68, 73—105.

RELATIVELY small additions of sodium chloride depress considerably the permeability of soil, the turbidity of the drainage water indicating the occurrence of a peptisation of the highly disperse clay which is to be attributed to electrification of the soil particles owing to interchange of ions. The effects of the liberal application of potassium salts to heavy soils are similarly explained.—T. H. P.

Humic soils; Estimation of the acidity of —. S. Odén. *Int. Mitteil. Bodenkunde*, 1919, 9, 361—374. *Chem. Zentr.*, 1920, 91, IV., 285.

AN estimation of the total acidity of a soil does not show the amount of humic acid, as a number of other acids are also present. The hydrogen-ion content of a soil is first determined by the potentiometer method; concentrated potassium chloride is then added to the test portion of the soil, and the hydrogen-ion content is again measured. The acids in the filtrate are also estimated by titration, and the total acidity and acidity are determined by the method of Tacke or Tacke-Süchting (*J.*, 1908, 171), whereby an indication of percentage of acids present which readily form only slightly soluble calcium salts is obtained.—L. A. C.

Sulphur; Relation of — to soil acidity and to the control of potato scab. W. H. Martin. *Soil Sci.*, 1920, 9, 393—403.
